
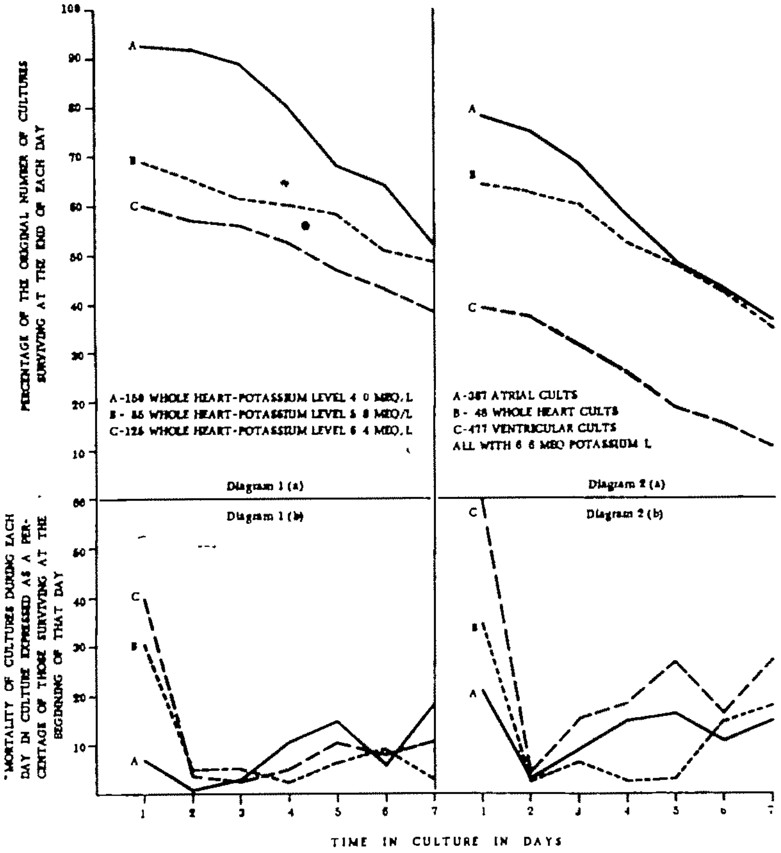

Figs. 1 and 2 The electrical functional survival and mortality of cultures of 6-day chick embryo whole hearts, isolated right atria and isolated right ventricles in supernatants of various potassium-levels

These series are grown in supernatants of different potassium-level and those in the supernatant of lowest potassium-level show the best 'survival'. The considerable initial 'survival' difference between the three series (particularly between series *A* and *B*) lessens with time. Supernatants *B* and *C* are made from the same serum containing lysed red cells but, since a low-potassium balanced salt solution is used to make supernatant *B*, they differ only in potassium-level. Thus, *B*'s better 'survival' makes it probable that, of lysed red cell products, the potassium has the greatest effect on 'survival' of hearts in culture. The small initial 'survival' in high potassium supernatants may be due to release of potassium from damaged muscle raising the total potassium-level around nearby healthy muscle fibres to the critical level which interferes with their electrical functions.

Fig. 1*b* shows the relationship between time and the number of hearts failing to 'survive' at the end of each day expressed as a percentage of the number of hearts surviving at the beginning of the same day. The first day's high 'mortality' supports the theory of the damaging effect of high local potassium-levels (a combination of high supernatant potassium and potassium released from damaged muscle). The potassium from damaged cells then diffuses into the general supernatant and the potassium-level around healthy cells is lowered, explaining the lessened 'mortality' during the second day. Thereafter, the slow rise in 'mortality' may be due in part to the progressive deficit of essential nutrients as they are utilized by the tissues. The potassium contents of salt solutions and supernatants commonly used in tissue culture are as follows: Eagle's solution, 4·09 m.equiv./l.; Dulbecco's, 4·2 m.equiv./l.; Osgood's, 5·2 m.equiv./l.; Gey's, 5·25 m.equiv./l.; Earle's, 5·4 m.equiv./l.; Melnick's, 5·6 m.equiv./l.; Hanks's *T.C.* 199 and Scherer's, 5·84 m.equiv./l. The potassium-level in several of them is above the physiological limits in humans and in the range which, according to the observations in this communication, causes a poor initial functional survival of hearts in culture.

Fig. 2*a* shows a comparison of the effects of the same high (6·6 m.equiv./l.) potassium supernatant on the electrical activity of 6-day chick embryo whole hearts, isolated right atria and isolated right ventricles in culture. Atria have the best, whole hearts next best and ventricles the poorest initial 'survival'. Atria and whole heart 'survival' differs only in the first four days in culture. The poor 'survival' of ventricles is not due to nutritional difficulties because of 'large' muscle bulk, for whole hearts have a larger bulk, nor to the relative amount of tissue damaged during explantation, for atria have a higher relative damage. It may result from the sensitivity of impulse-generating and conducting tissue to high potassium-levels since whole heart and isolated atrium have a higher proportion of such tissue than isolated ventricles. However, the best explanation for the poor 'survival' of ventricles in high potassium supernatants is that, since the isolated right atrium and whole heart have previously established initiating foci for contraction and the isolated right ventricle has to establish a new focus, the new focus is more sensitive to high potassium-levels than the older established foci.

Fig. 2*b* is similar to Fig. 1*b* and compares the daily 'mortality' percentages for whole hearts, isolated right atria and isolated right ventricles maintained in the same high-potassium (6·6 m.equiv./l.) supernatant. The lowest 'mortality' occurs during the second day, possibly for the reasons postulated in the discussion of Fig. 1*b*. Thereafter, the 'mortality' rises at a faster rate than for hearts in Fig. 1*b*. The whole-heart series shows the best and the ventricles the poorest relative 'survival' behaviour. Further studies of the factors affecting the 'survival' of hearts in culture is being undertaken.

Measurement of the Intrahepatic Shunted Flow of Blood in Cirrhosis of the Liver

THE most characteristic change in the hepatic circulation in cirrhosis of the liver is the appearance of pathological anastomoses in intrahepatic and extrahepatic blood vessels. The formation of intrahepatic and extrahepatic shunts markedly decreases the flow of blood through sinusoids, and increases the disturbance of liver cell function and liver cell damage, becoming one of the etiological factors of hepatic coma. Since there is apparently no published report of the quantitative measurement of the shunted flow of blood in liver cirrhosis, we have devised methods of measuring the intrahepatic and extrahepatic shunted flow in clinical cases. In this communication, the methods are presented for measuring the intrahepatic shunted flow of blood in cirrhosis of the liver. By these methods considerable amounts of intrahepatic shunted flow of blood is demonstrated in moderate and advanced liver cirrhosis.

The intrahepatic shunted flow of blood is measured either by the single administration method or by the continuous infusion method.

Single administration method. After the injection of an aqueous solution of 0·5 gm./kgm. body-weight of galactose in a single dose, blood is taken at successive intervals from the hepatic vein by means of hepatic venous catheterization and also from an arterial indwelling needle previously laid in the brachial artery. Quantitative analysis of galactose of these blood samples and urine is determined by a modified Fischer's[1] method. In normal subjects, at first, the peripheral arterial concentration curve shows the linear downward course, and hepatic venous concentration parallels the peripheral concentration, finally reaching zero level (first phase). When afterwards the amount of galactose entering the liver decreases below the maximal removing capacity of the liver, the peripheral concentration curve takes the shape of a simple exponential curve, and hepatic venous concentration remains at zero level (second phase). The hepatic flow of blood is calculated from the disappearance constant of the peripheral concentration in the second phase (k_2), the volume of distribution (V), and average urinary clearance of galactose (U_{cl}), according to the following modified equation of Waldstein[2]:

$$F = \frac{k_2 V - U_{cl}}{\left(1 - \frac{0\cdot4 \times \text{hæmatocrit}}{100}\right)} \times \frac{1}{\text{surface area}}$$

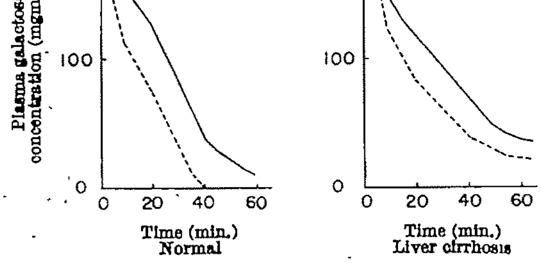

Fig. 1. Peripheral arterial (———) and hepatic venous (- - - - -) galactose concentration curves by single administration method in a normal subject and in a patient with advanced liver cirrhosis

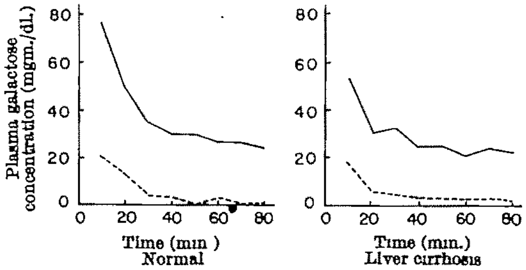

Fig. 2. Peripheral arterial (———) and hepatic venous (- - - - -) galactose concentration curves by continuous infusion method in a normal subject and in a patient with mild liver cirrhosis

When there is an intrahepatic shunt between portal and hepatic veins in liver cirrhosis, the concentration in the hepatic vein does not drop to zero in the second phase, that is, galactose flows into the hepatic vein through the shunt, and the hepatic venous concentration curve in this stage takes the form of a simple exponential curve, too (Fig. 1). Therefore, in the presence of an intrahepatic shunt, the above equation does not give the total amount of blood flowing through the liver, but gives the amount of blood which enters the sinusoids in unit time, namely, effective hepatic flow of blood. On the same principle as in the Diodrast or *para*-aminohippuric acid clearance in renal physiology, total and shunted hepatic flow of blood can be calculated from effective hepatic flow of blood ($EHBF$) and the extraction ratio in the second phase (E).

$$\text{Total hepatic flow of blood } (THBF) = \frac{EHBF}{E}$$

$$\text{Shunted hepatic flow of blood } (SHBF) = THBF - EHBF$$

Continuous infusion method. After a priming dose of 10 gm. of galactose, constant infusion of galactose is made at a rate that does not exceed the maximum removing capacity of the liver, which is usually 200 mgm. per min. The curves become horizontal after 40 min. (Fig. 2). The total hepatic flow of blood is calculated on the basis of Fick's principle[3].

$$THBF = \frac{I_m - U_m}{(P - H)\left(1 - \frac{0\cdot4 \times \text{hæmatocrit}}{100}\right)} \times \frac{1}{\text{surface area}}$$

(I_m is galactose infused per min., U_m galactose excreted into urine per min., P peripheral plasma concentration, and H hepatic venous plasma concentration.) On the same principle as by the single administration method, the effective and shunted flow of blood is calculated:

$$EHBF = THBF \times E$$

$$SHBF = THBF - EHBF = THBF\ (1 - E)$$

In normal subjects the extraction ratio was in the vicinity of 100 per cent, and there was no estimated intrahepatic shunted flow of blood. In four cases with mild liver cirrhosis, the shunted flow of blood was 0–155 c.c./min./sq.m. or 0–20 per cent of the total hepatic flow of blood. In eleven cases with moderate or advanced cirrhosis, on the other hand, the shunted flow of blood was calculated at 62–867 c.c./min./sq.m., or 18–78 per cent of the total hepatic flow. On the average, about half the total hepatic flow by-passed the liver in liver cirrhosis. Depressed extraction ratio was also noticed in two out of four cases with viral hepatitis in the icteric stage. Therefore, the intrahepatic shunted flow of blood calculated in this experiment is generally considered to include not only the flow of blood through the anatomic shunt, but also the functional shunted flow of blood due to hepatic dysfunction.

Inhibition of Monoamine Oxidase by Benactyzine *in vitro* and *in vivo*

VOJTĚCHOVSKÝ[1] has found recently that large doses of benactyzine (the diethylaminoethyl ester of benzylic acid) exert a psychotogenic effect. In doses of 40–200 mgm. it reduces the excretion of 5-hydroxyindole acetic acid in the urine to unmeasurable values[2]. These effects manifested themselves simultaneously. We suspected that benactyzine inhibits the monoamine oxidase which participates in the inactivation of serotonin[2]; and to confirm this hypothesis we tried to follow the effect of benactyzine on monoamine oxidase *in vitro* and *in vivo*.

For estimation of the activity of monoamine oxidase we used a 33 per cent homogenate of rat liver and 50 per cent homogenate of rat brain. The activity was determined using the modified method of Sjoerdsma *et al.*[3]. Instead of a decrease of serotonin we estimated production of 5-hydroxyindole acetic acid. After deproteinization of the homogenate with hydrochloric acid, we used the method of Udenfriend *et al.*[4], and the type of inhibition was determined by using Lineweaver and Burk's method[5]. Inhibition of monoamine oxidase *in vivo* was investigated in a homogeneous group of seven white rats, Wistar strain, weighing 200–250 gm. Benactyzine was administered subcutaneously in doses of 35 mgm. per 100 gm. body-weight. Normal values were obtained in a similar group of seven animals to which no benactyzine was administered. The animals were followed up for 60 min. following the dose of benactyzine and were afterwards killed.

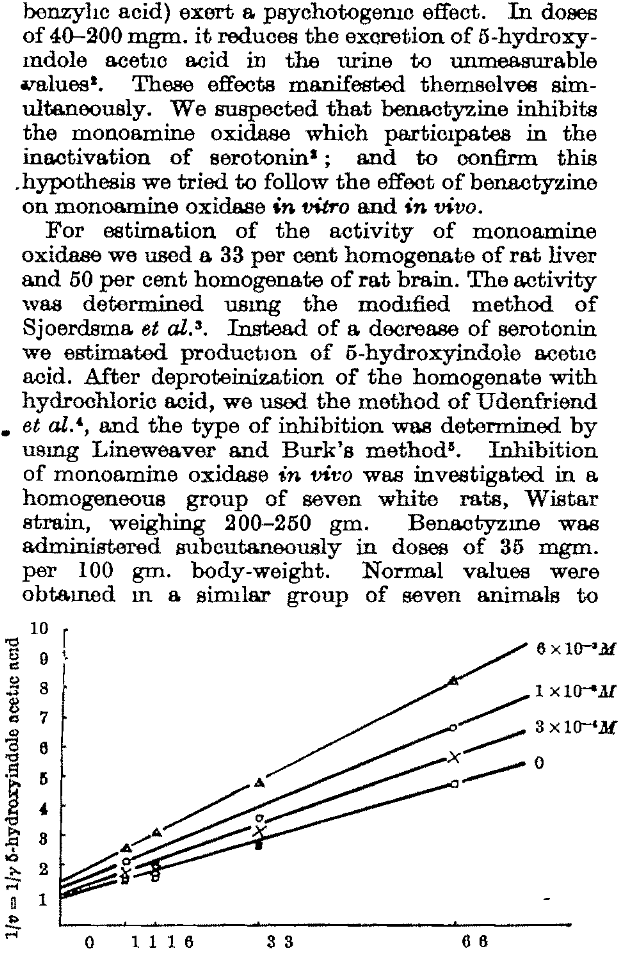

Fig. 1. Lineweaver–Burk plot of benactyzine inhibition as a function of 5-hydroxytryptamine concentration

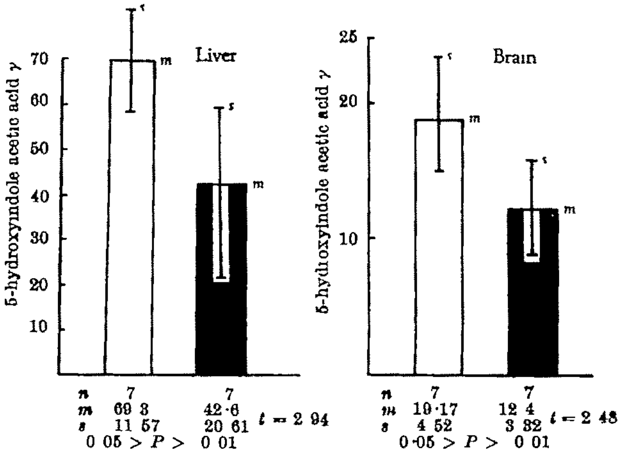

Fig. 2. Activity of monoamine oxidase *in vivo*

After homogenizing the brain and liver of both groups, monoamine oxidase activity was estimated[4].

Our experiments showed that benactyzine in concentrations of 4×10^{-3} *M* inhibits monoamine oxidase by 29 per cent, 4×10^{-4} *M* not at all; under similar conditions, 4×10^{-3} *M* 'Marsilid' inhibits it by 40 per cent and at concentrations of 4×10^{-4} *M* by 9 per cent. Benactyzine is thus a weaker inhibitor than 'Marsilid'. As shown by Fig. 1, benactyzine acts as a non-competitive inhibitor. Fig. 2 illustrates the inhibition of monoamine oxidase *in vivo*. It presents average values of the activity of the enzyme in the liver and in the brain; normal values, white columns; after benactyzine, black columns. Fig. 2 shows the variation of values and their statistical significance. Benactyzine when used in the above doses inhibits *in vivo* the monoamine oxidase in rat liver by 38·5 per cent on an average, and in rat brain on an average by 40 per cent. The results are somewhat distorted by the fact that two animals were resistant to benactyzine; thus they showed no signs of intoxication, and their behaviour did not change. In these animals no inhibitory effect was revealed in the organs investigated. This seems to us to explain also the great variations of values following the administration of benactyzine.

From our experiments it appears that benactyzine is a non-competitive inhibitor of monoamine oxidase *in vitro* as well as *in vivo*.

We are indebted to Mrs. J. Doubravová and Miss V. Kordová for technical assistance, and to Prof. V. R. Pickles, University of Sheffield, and to Sandoz, Ltd., Basle, for generous gifts of 5-hydroxytryptamine.

Antigen-induced Damage to Isolated Sensitized Mast Cells

THERE is now quite convincing evidence that damage to mast cells always occurs when histamine is released during anaphylaxis. Thus damage to these cells is known to occur after active or passive sensitization either when antigen is injected in the intact animal or when a piece of sensitized tissue is incubated with the specific antigen[1]. However, all the evidence is derived from experiments made with tissues containing not only mast cells but also a mixed cell population, and therefore it is not possible to know whether damage to the mast cells is a direct consequence of the antigen–antibody reaction or whether antibodies are located on or in the mast cells.

We present here the results of some experiments performed in order to find out whether isolated mast cells would react to the specific antigen. Wistar rats of both sexes and weighing 150–250 gm. were used. The animals were sensitized by injecting 1 ml. of horse serum plus 1 ml. of *Haemophilus pertussis* vaccine containing 20,000 million organisms intraperitoneally and were used twenty-five days later. Mast cells were isolated by a method similar to that described by Padawer and Gordon[2]. The animals were bled under ether anæsthesia and 2 ml. of saline (sodium chloride 0·85 per cent) containing 50 μgm. heparin per ml. were injected into the abdominal cavity, and gentle massage of the gut through the abdominal wall was performed for about 1 min. The abdominal wall was then incised along the mid-ventral line and the fluid from the abdominal cavity collected with a pipette. This was carefully layered over 1·5 ml. of a 30 per cent water solution of bovine serum albumin (fraction *V*., Armour) and centrifuged in an International refrigerated centrifuge model *PR* 1 at 900 r.p.m. for 2 min. The albumin solution was then removed with a pipette, avoiding contamination with interface cells, diluted to 20 ml. with Tyrode solution and centrifuged at 1,000 r.p.m. for 5 min. This last operation was repeated once more and finally the deposit in the bottom of the tube was resuspended in 0·2–0·3 ml. Tyrode solution. This procedure resulted in a suspension containing 90–98 per cent of mast cells most of which were well preserved. These cells were then studied by aid of phase contrast microscopy either under dry magnification (× 800) or with oil immersion objective (× 1,000). A drop of the mast cell suspension was placed on a slide and covered with a square coverslip two sides of which were sealed with melted paraffin. A small well of paraffin was then made at each free side of the coverslip in the same way as was described by Strangeways and Canti[3], the preparation kept in a warm stage at 37° C., and a suitable group of well-preserved mast cells selected for observation. Horse serum heated at 37° C. was then placed in one free side of the coverslip and sucked on to the cells with a piece of filter paper. Usually the mast cells stood still when the antigen was sucked through, although sometimes many were washed away. As a control to these experiments the effect of horse serum on non-sensitized mast cells was also observed.

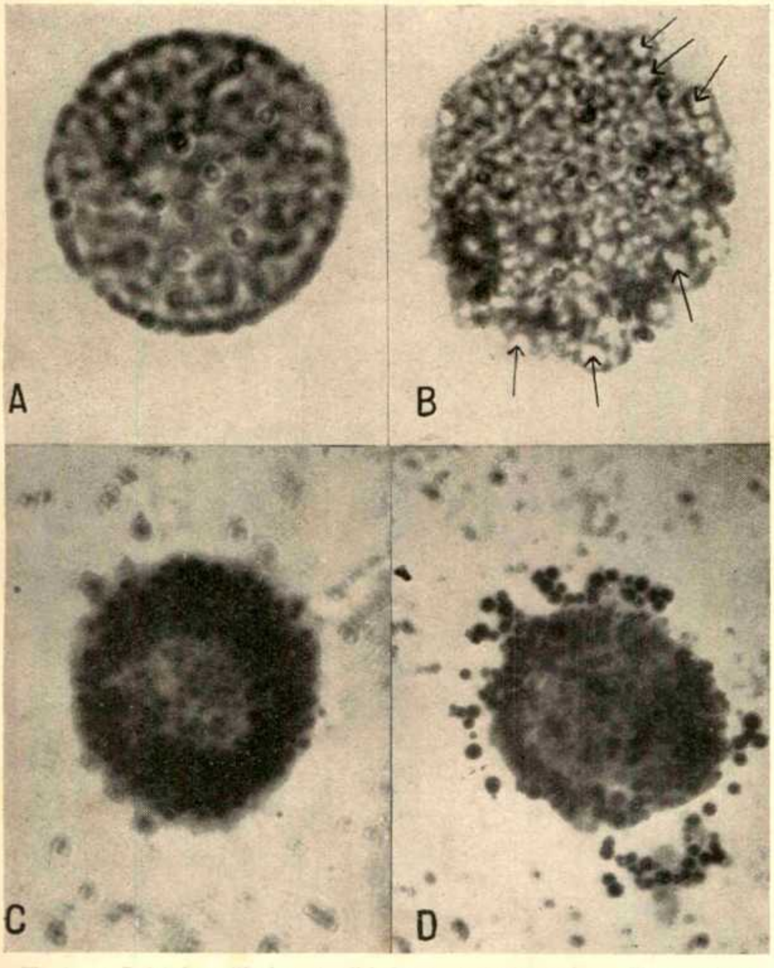

Fig. 1. *A*, Isolated sensitized mast cell before contact with antigen. Phase contrast (× *c*. 666); *B*, the same cell after contact with antigen. Arrows point to vacuoles (× *c*. 666). *C*, Isolated mast cell after fixation with 1 per cent formaldehyde and stained with toluidine blue (× *c*. 533). *D*, Isolated mast cell after contact with antigen. Note granules outside the cell. Fixed and stained as stated above (× *c*. 533)

In these conditions the effect of the antigen on sensitized mast cell was a very striking one. A few seconds after the antigen had been sucked on to the cells there was a slight increase in cell size followed by a sudden appearance and disappearance of successive vacuoles which made the cell look as if it were 'bubbling'. Sometimes it was possible to observe extrusion of the granules, which occurred, so far as could be observed, without damage to the cellular membrane. This phenomenon was very rapid, but was slowed down by low temperature and could be more easily followed at 25° C.—a temperature at which the phenomenon took as long as 1 min. to complete. When cell change was no longer seen, the cell had lost its regular contour, the granules had become more apparent and large empty spaces could be seen among them (Fig. 1). However, we were not able to see any alteration in the form of the mast granules, most of which remained inside the cell. This phenomenon is very like that produced by compound 48–80 on rat mast cell[4]. The very conspicuous damage induced to mast cells in anaphylaxis[1] led us to propose the hypothesis that mast cells might contain antibodies[1]. Later on, Humphrey and Mota[5], concluded that the antigen–antibody reaction in anaphylaxis must occur in, or very near, the mast cells. However, at that time no direct proof could be produced that the mast cells contain antibodies. Our present results showing that washed isolated mast cells taken from sensitized animals are still able to respond to the specific antigen strongly suggest that mast cells contain antibodies and that damage induced to these cells in anaphylaxis is the consequence of an antigen–antibody reaction occurring in the mast cell itself. How the antigen–antibody complex once formed damages the cell is a challenging problem. However, there is some evidence that antibodies are located on the cell surface[5], and if it is assumed that γ-globulin is one of the protein constituents of the cell membrane, its combination with antigen could disturb the molecular equilibrium of the membrane and in so doing start the process of cell damage. Further experimental work is needed on this point.

'Weightless' Micro-electrodes for recording Extracellular Unit Action Potentials from the Central Nervous System

IN order to record the activity of single nerve cells in the mammalian central nervous system it is necessary to maintain the tip of the recording electrode (a micropipette or metal needle) within some 30μ of the cell body[1]. The skeleton of the animal is usually rigidly clamped to a heavy metal base and in many experiments this base also carries the micro-electrode upon a rigid support. Unfortunately the exposed central nervous system expands with every beat of the heart and also with exhalation of air from the lungs. Because such movements can make records of unit activity difficult or impossible to obtain, a technique has been developed[2,3] for recording from cells in the cerebral cortex in a rigidly enclosed cranial cavity. This system has proved so successful that lengthy records can be obtained from unanæsthetized, mobile animals. There are, however, limitations to this technique. It is not readily adaptable to exploration of a wide area of cortex; moreover, it cannot be applied to an examination of the spinal cord or brain-stem. For this reason we have developed the 'weightless' micro-electrode described below.

The principle of the device illustrated in Fig. 1 is to suspend the micro-electrode (with its tip appropriately placed) from a spring which is sufficiently light to allow the electrode to follow movements of the nervous system. A weak spring *S* is soldered at the upper end to a length of brass rod *R*; the lower end of the spring is soldered to a trace *T* which encircles a strip of thin celluloid *C* carried on a transparent 'Perspex' collar fixed on the end of the protective glass tube *G* that encases the whole assembly. The lower part of the diamond-shaped trace *T* is soldered to a chlorided silver wire; when the micropipette *M* is screwed into the conical-spring *CS* the chlorided silver wire dips into the saline that fills the butt of the electrode. The trace *T* also carries two central prongs *P* so arranged that they are in line and separated at the tips by a distance *d* where $d - (\text{celluloid thickness}) \simeq 1$ mm. Electrical connexion with the cathode follower input is made through the whole metallic system supporting the weight of the micro-electrode.

The dimensions of the system are unimportant and cannot very well be decided without prior knowledge of the average weight of an electrode and the strength of the spring. In general, the electrodes used should be as light as is convenient for handling; the mass of trace and spring should be kept small, and the spring itself should be stretched to at least 150 per cent of its resting length by addition of the electrode. The dimensions of the instrument which we are using are provided in Fig. 1.

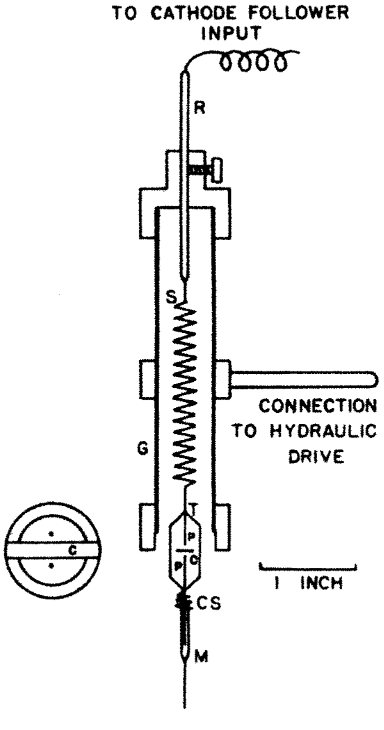

Fig. 1. *S*, Spring of 0·0054-in. nichrome wire; *T P*, trace of 0·0075-in. stainless steel; *M*, micropipette of average weight 70 mgm. when fitted. Other details are provided in the text

After attaching a particular micro-electrode, the electrode is weighed by raising or lowering *R* in relation to the upper 'Perspex' cap until the prongs *P* of the trace just ride clear of the celluloid gate *C*. The whole assembly may now be attached to an appropriate drive by a third 'Perspex' collar encircling the tube *G* and swung into position over the exposed nervous system. During insertion of the micro-electrode, as the whole carriage descends and the electrode touches the surface the celluloid gate comes in contact with the lower prong *P*. Insertion is continued until the micro-electrode's tip encounters a cell suitable for recording. If possible, it is desirable to descend 50–100μ below the optimal recording position; when the drive is reversed and an attempt is made to withdraw the electrode, the celluloid gate loses contact with the lower prong of the trace. Considerable movement of the whole carriage now leads to very small movements (in the same direction) of the micropipette, which is 'floating'. In this way the desired cell can be found again and, ideally, recording should be begun only when the celluloid gate is half-way between the two prongs. An instrument of this form must be designed to meet the owner's particular requirements. Our own carriages permit ±200μ upward or downward movement of the nervous system and allow ±2 mm. lateral movement of the preparation without loss of the record from a single unit. Lateral movements of 2 mm. can be made without causing any detectable alteration in amplitude of recorded spikes. This system completely eliminates the periodic variations of spike height which are due to respiration and the pulse in the fully exposed brain or brain-stem, and allows one to record from single units (deeper than about 100μ) for 6 hr. or more.

HÆMATOLOGY

Bacterially Mediated False-Positive Reactions in Lytic Blood-Typing Tests

IN blood-typing tests which employ lytic techniques, false-positive reactions can be brought about by the use of improperly rinsed and improperly dried test-tubes that still contain residues of acid or detergent or traces of water. In the course of performing routine blood-typing tests on citrated samples of cattle blood sent into this laboratory for blood-group analysis[1], we have encountered certain false-positive reactions which cannot be attributed to the use of dirty tubes. Rather, they appear to be of the order of true antigen–antibody reactions.

It is observed that the red cells in certain infected or bacterially contaminated samples of cattle blood are modified or transformed in such a manner that they react with certain natural antibodies which do not react with and cannot be absorbed by unmodified cattle red cells. These particular natural antibodies seem to be universally present, in varying concentrations, not only in virtually all our cattle blood-typing reagents[1] but also in fresh rabbit serum which is used as complement in the cattle tests.

We believe that these bacterially mediated transformations of cattle red cells may be closely akin or identical to the well-known transformations of human red cells—the Thomsen hæmagglutination phenomenon—brought about by certain bacteria or their filtrates[2]. At present, the main difference seems to be in the manifestation of the serological reactions. Transformed human red cells are said to be panagglutinable. That is, they agglutinate in virtually any serum including the autologous serum. Transformed cattle red cells are rarely if ever panagglutinable, an observation made long before us by Friedenreich[2]. This is in keeping with the observation that unmodified cattle red cells rarely exhibit agglutination even when sensitized with multiple doses of blood-typing antibodies—a fact which has necessitated the use of lytic techniques in the cattle studies[3].

Transformed cattle red cells, when sensitized with sufficient natural antibodies, are usually lysed in the presence of an appropriate complement (C') such as that in fresh rabbit serum. Whether they will be lysed by the action of natural antibodies and C' seems to depend largely on the degree of transformation and upon the concentration of natural antibodies not only in the various dilutions at which our blood-typing reagents are used but also on the concentration of natural antibodies in fresh rabbit serum.

When the red cells are what we shall refer to as maximally transformed, they are essentially panhæmolytic. That is, they become lysed in the tests with each reagent and also in the complement controls. Therefore, the complement controls alone are usually adequate in screening maximally transformed cattle red cells. Such controls are not, however, adequate in screening minimally transformed cattle red cells, and herein lies the fallacy in the notion that complement controls in conjunction with saline controls are sufficient to detect those samples of blood which are unfit for typing in lytic tests. The complement controls alone will not do this because, in our experience, the concentration of natural antibodies in pooled rabbit serum is usually not above a threshold necessary to bring about lysis of minimally transformed cattle red cells during the ordinary time-course of the blood-typing tests. When minimally transformed red cells are lysed in the complement controls, the lysis may not begin to make its appearance until the final reading (check-reading) of the tests and it is usually of a very weak degree. Furthermore, in the absence of reactions brought about by the specific blood-typing antibodies, the minimally transformed red cells seem to maintain their stability as well as or even better in tests with the majority of our reagents than they do in the complement controls. We suspect, as indicated by titrations, that certain constituents in the serum of the reagents exert a protective influence on the transformed red cells.

Some of our reagents, however, are rather richly endowed with the offending natural antibodies, and it is in the tests with such reagents that lysis of minimally transformed red cells takes place in spite of the protective influence of the serum. Such reactions can simulate closely those brought about by the specific blood-typing antibodies, thereby providing a previously unsuspected and a particularly subtle kind of false positives in lytic tests.

The observations which led us to the discovery of false positives of this order is another story which we hope to publish elsewhere along with results of transformation of cattle red cells brought about not only by various bacteria isolated from cattle blood samples but also with borrowed cultures of organisms known to transform human red cells. In the meantime, it may be well to mention at least one of the steps which we have taken in order to detect those samples in which the red cells may be minimally transformed. In addition to being cognizant of those reagents which are richly endowed with natural antibodies and are thereby capable of producing false-positive reactions with minimally transformed red cells, we employ, as a control, a bovine serum which contains no specific blood-typing antibodies but does contain natural antibodies in sufficient concentration to react with minimally transformed red cells. Red cells which become lysed in this reagent are regarded as transformed and are thereby subjected to close scrutiny with respect to their reactions with the regular blood-typing reagents. When there is any doubt regarding the latter reactions, antibody-absorptions can be performed to distinguish those reactions which may be brought about by natural antibodies rather than by the specific blood-typing antibodies.

Antithromboplastin in Human Serum and Plasma

THE existence of antithromboplastin as a blood coagulation factor has been well documented (for example, see ref. 1). While it is likely that antithromboplastin plays a part in the prevention of blood coagulation in the body in health, it does not appear to have been characterized physiologically. Berry[2] has indicated a suitable technique for its demonstration which we have applied with slight modifications in detail only to whole serum, whole plasma (platelet-free) and also to the electrophoretic fractions of serum and plasma. These fractions were eluted by mechanical squeezing from strips cut from pieces 36-cm. wide of Whatman No. 3 paper used in a 'fakir's mattress' type of electrophoresis apparatus[3]. Our technique was, basically, to incubate serum, plasma or the electrophoretic fractions with human brain thromboplastin and calcium chloride at 37° C., and at known intervals to add an aliquot of this incubation mixture to a substrate platelet-free plasma and note the time it takes to clot. A saline control repeatedly gave coagulation times of about 20 sec. (shown as 100 units on the ordinate in Fig. 1). It should be noted that this technique demonstrates antithromboplastin active only against the extrinsic tissue type of thromboplastin and not against the thromboplastin formed by blood undergoing the natural coagulation mechanisms (intrinsic thromboplastin).

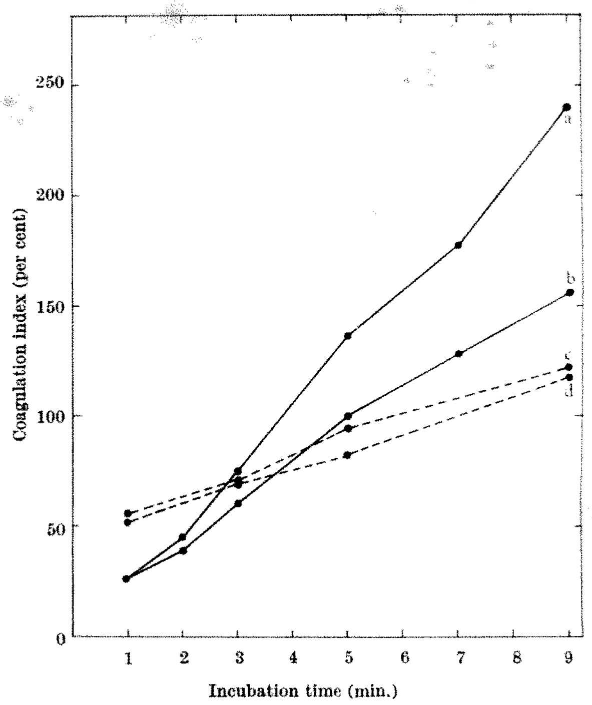

Fig. 1. Curves (*a*) and (*c*) show the progressive retardation effect of plasma and serum respectively on brain thromboplastin. Curves (*b*) and (*d*) show the effect after the addition of thrombin. The units of the ordinate are percentages. All coagulation times, including those in Table 1, were expressed as percentages of the saline control, so as to overcome differences due to slight day-to-day variations in the latter

Serum, when thus treated, showed an initial acceleration followed by a progressive lengthening of coagulation times (curve *c*). It is this progressive inhibition of the thromboplastin, claimed by Berry[2] to be due to an antithromboplastin, which can be estimated semi-quantitatively by the gradient of the curve ; steeper curves indicating greater amounts of activity.

Plasma showed a greater level of activity than serum (curve *a*). The initial acceleration of coagulation in both cases is probably due to the presence of factor VII, since it is absent after absorption by aluminium hydroxide[2]. The eluates from the α_1-globulin region of serum show an accelerating effect (that is, a coagulation index less than the 100 per cent control-level) ; see Table 1, column *a*. This, again, is probably due to factor VII, which has been shown to migrate in this region[4]. We cannot explain the accelerating effect seen in the β-globulin region. It is possible that it is associated with lipoproteins, many of which migrate in this zone.

Retarding effects appear in the α_2-globulin and the γ-globulin regions in both serum and plasma (columns *a*, *c* and *d*). Only in plasma is the retarding effect from both these regions progressive (column *d*) and therefore probably due to antithromboplastins. From columns *c* and *d* it can be seen that there is an increase in coagulation times when the fractions are incubated for 2 min., and then for 1 hr. In serum, this progressive retardation is seen only in the α-globulin region (column *c*). This suggests that there are two circulating antithromboplastins ; one, which migrates in the α-globulin region, present in serum

Table 1. COAGULATION TIMES (PERCENTAGE OF NORMAL) OF ELECTROPHORETIC FRACTIONS

Electrophoretic fractions		Serum	Serum plus thrombin	Difference in times after 2- and 60-min. incubation	
Stainable protein	Fraction No.	(*a*)	(*b*)	Serum (*c*)	Plasma (*d*)
Albumen	1	87	35	−7	3
,,	2	81	26		
,,	3	76	34	19	4
α_1-Globulin	4	84	31		
None	5	84	62	14	36
α_2-Globulin	6	98	124		
,,	7	109	117	13	22
β-Globulin	8	80	30		
,,	9	72	32	4	19
None	10	81	26		
γ-Globulin	11	107	26	−6	37
,,	12	132	23		
,,	13	125	35	−6	47
,,	14	100	34		

The difference in times in columns (*c*) and (*d*) is given in the sense: (time after 60 min. incubation) minus (time after 2 min. incubation). The fractions in columns (*c*) and (*d*) were paired in order to conserve materials.

and plasma, and another, migrating in the γ-globulin region, in plasma only.

Further evidence for two antithromboplastins was shown by the effect of adding a preparation of thrombin to the incubation mixtures. The amount of thrombin added was that which shortened the coagulation time of a saline - thromboplastin - calcium chloride mixture from 28 to 16 sec. When added to serum during incubation, no effect on the steepness of the curve was produced (curve *d*), but there was a marked decrease in antithromboplastic activity when thrombin was added to plasma (curve *b*).

When thrombin was added to the electrophoretic fractions during incubation, the retarding action in the γ-globulin region was neutralized (column *b*). The presence of long coagulation times in the α_2-globulin region in this column cannot, however, be assumed to be due entirely to antithromboplastin. It is probably also partly due to antithrombin, which is known to migrate in this region[4]. (Note that the activity in this region in column *b* exceeds the 100 per cent control level—a somewhat unexpected finding.)

The above findings suggest to us that there are two circulating antithromboplastins in plasma. One of them (the γ-globulin one) is neutralized by thrombin and presumably also during normal coagulation processes; and the other one in the α-globulin region remains unchanged throughout and is present in serum.

We thank Prof. K. R. Hill, Dr. Francis Gardner, and Dr. A. T. Richardson for their encouragement in this work.

Determination of Calcium in Blood Serum by Atomic Absorption Spectroscopy

ALTHOUGH many methods have been described for the determination of calcium in blood serum, they give results which vary over a range of nearly 20 per cent[1,2], and there is still no agreement as to which method is the most reliable. In general, the values given by the flame photometric methods are 3–4 per cent higher than those obtained from the classical oxalate–permanganate titration, which in turn are about 10 per cent higher than those given by complexometric and colorimetric methods, while the values given by spectrographic emission methods are lower still.

A completely new approach to the problem is afforded by the development of the technique of analysis by atomic absorption spectroscopy[3,4], and, following the development of a simple method[5] for determining serum magnesium by this means, I have now investigated the determination of serum calcium also.

With the same equipment as in the earlier work, but using a calcium hollow-cathode tube and passing the radiation through the lowest part of the air-acetylene flame, just above the zone of unburnt gas, accurate measurements of the absorption of the calcium resonance line (4227 Å.) were possible in solutions containing 5–15 p.p.m. calcium. The presence of phosphorus lowers the absorption markedly; but this can be entirely overcome by the addition of large concentrations of strontium chloride or of the disodium salt of ethylenediamine tetraacetic acid. Provided a rich acetylene–air mixture is used, the protein in serum nullifies the effect of the phosphate present, and for routine purposes measurements can be made on serum diluted 10- or 20-fold with water. Since only 2·5 ml. of solution are required for duplicate calcium determinations, less than 0·2 ml. of serum is required for the estimation of this metal. Magnesium, even in quantities far in excess of its concentration in serum, is without effect on the calcium absorption. The sodium and potassium present in serum have only a small influence on it, which is allowed for in any event by standardizing the instrument with solutions of calcium containing about the same concentration of sodium as do the serum solutions.

Table 1 shows calcium contents of sera obtained in the following ways: (*a*) The calcium was precipitated as oxalate, and the supernatant liquid removed by draining after centrifuging. The precipitate was dissolved in a drop of hydrochloric acid and made

Table 1. CALCIUM CONTENT (MGM./100 ML.) OF BLOOD SERUM

Serum No.	Type	(*a*) Calcium pptd. as oxalate	(*b*) Serum deproteinized	(*c*) Serum diluted with water	Oxalate-permanganate titration
1	Bovine*	11·15	11·35	11·0	11·1
2*A*	Equine†	8·5	8·95	8·6	9·1

19	,,	—	9·35	—	8·8

* Freeze-dried serum.
† This sample had stood in the refrigerator for several months and was centrifuged to remove the precipitate which had formed.

up to 5 ml. with strontium chloride solution (2,500 p.p.m. strontium). (*b*) The serum solution was deproteinized by the addition of trichloracetic acid containing strontium chloride and measurements were made on the supernatant liquid after centrifuging. (*c*) The serum was diluted directly with water to 5 ml.

It will be seen that there is good agreement between the values obtained for the calcium content of serum by these three variations of the atomic absorption technique, and that in general the results are slightly higher than the values obtained by the oxalate–permanganate titration. There is a small but significant difference between the results obtained by methods (*a*) and (*b*), which is of the magnitude to be expected from a combination of two factors, namely: (1) the failure of the oxalate buffer to precipitate the last 0·8–2·0 per cent of serum calcium[6] and (2) the decrease in volume, estimated at 0·5 per cent, of the serum solution after deproteinization in method (*b*).

It is clear that method (*b*) is an accurate procedure for determination of calcium in serum, while method (*c*) gives very rapidly results which may be of sufficient accuracy for many purposes.

A fuller account of this and the earlier[5] work will be submitted to *Spectrochimica Acta*.

PATHOLOGY

Cirrhosis of the Liver induced in Rabbits by Gastric Instillation of 3-Monohydroxycholanic Acid

Daily administration to rabbits of a desiccated whole bile preparation rapidly gives rise to cirrhosis of the liver[1]. Later findings suggested that the effect was linked to the activity of bile acids[2] although several of the first tested and more common variants of them showed only a feeble liver damaging effect when used according to the present method[2].

On the basis of further analysis of the dried bile preparation, several variously substituted cholanic acid derivatives have been investigated. Of the bile acids so far tested 3-monohydroxycholanic acid (lithocholic acid) has been found highly effective. Daily gastric instillation to rabbits (mean weight 2·5 kgm.) of 10 ml. of a 0·5 per cent water suspension of the sodium salt of this acid (L. Light and Co., Ltd.) induced cirrhosis of the liver in 10 of 11 animals within three months. In several control groups of equal size no cases of cirrhosis were found. Higher concentrations led to more extensive liver damage and death of the animals.

Massive fat infiltration was not observed. The extent of necrosis varied with the dose administered and the individual resistance of the animal. Hydropic degeneration of the liver cells was prominent. The ultimate picture was usually that of a finely nodular diffuse cirrhosis. A detailed report will be published elsewhere.

Estimation of Mouse Tumour Blood Volumes employing a Radioactive Isotope Technique

Changes in radiosensitivity and growth-rate in a serially irradiated line of the mouse sarcoma 37 have been reported elsewhere[1]. The effect of oxygen concentration on radiosensitivity has been reviewed recently by Gray[2] and might have contributed to the results obtained with sarcoma 37. The reduction in growth-rate in the serially irradiated line may have been due wholly, or in part, to a less-adequate development of blood vessels and capillaries within the tumour—resulting in longer diffusion paths. The evaluation of the internal vascularity of control and irradiated-line tumours was undertaken in an attempt to elucidate the causes of the observed changes. Macroscopic observations of the tumours *in situ* (developing on the abdominal skin) indicated a comparable increase in size of the cutaneous vessels in control and irradiated-line tumours.

Evaluation of the internal vascularity was undertaken by counting the ionization events within excised tumours after blood-labelling with a suitable tracer. This technique was possible owing to the lack of necrotic regions and blood sinuses in these tumours below a weight of approximately 700 mgm. The radioactive isotope employed had to be bound to a relatively inert molecule incapable of diffusion through the capillary walls. Radioiodine (^{131}I) bound to human serum albumin and suspended in a buffered saline[3] conformed to these requirements. This preparation was kindly made available by the National Institute for Medical Research, Mill Hill, London, N.W.7. The activity was of the order of 350–400 μc. per ml. on preparation.

The solution was injected into a lateral tail vein of lightly anæsthetized mice. Owing to the small quantity available from each preparation (about 3·5 ml.), approximately equal numbers of mice from each group were injected from each batch. Some batches produced a marked anaphylaxis, consequently the volume injected varied between 0·25–0·15 ml. per mouse. 3–5 min. after injection were allowed for mixing before killing by cervical dislocation. The tumours were then immediately excised, blotted with No. 5 filter paper and weighed. A blood sample was taken from the heart, placed in a 'Perspex' chamber of about the same volume as the tumour and weighed. Activity counts were made by a scintillation counter on the tumour, blood sample and background. The weight of blood in each tumour was calculated from the resulting data.

The results of these measurements for 19 irradiated *B* line (*B*12) and 22 control tumours are shown in Fig. 1. Blood weights are plotted against tumour weights on a double logarithmic scale. The trend

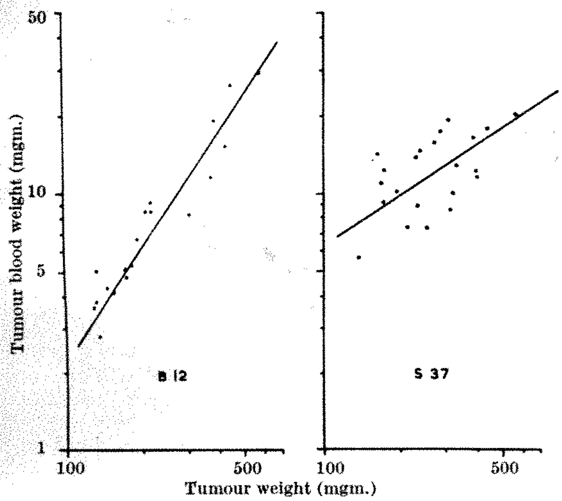

Fig. 1. Estimations of tumour blood proportions in sarcoma 37 and its serially irradiated line *B*12

lines for *B*12 and control data corresponded to slopes of 3/2 and 2/3 respectively. The scatter for *B*12 tumours was small, the correlation coefficient being 0·948—indicating a high degree of correlation (perfect functional relationship being unity). For control tumours a wider scatter was apparent, the correlation coefficient being 0·584—indicating the presence of a trend, but with a low degree of correlation.

The smaller blood volume values in *B*12 as compared with control tumours below a weight of about 350 mgm. (comparable to a tumour area of about 35 sq. mm.) suggest that the increase in time of tumour establishment experienced with this line may be due to a reduced vascular response by the host to the initial implant. A comparison of the trend lines and values for tumour weights greater than 350 mgm. indicates that vascularity is not a factor in explaining the reduction in growth-rate of established irradiated-line tumours.

The high degree of correlation between blood and tumour weights experienced with the *B*12 tumour results would appear to indicate that accurate evaluations of tumour blood content can be made by this technique.

Synovial Proliferation induced by Polysaccharides

ONE of the characteristic histopathological changes that occur in rheumatoid arthritis is the formation of pannus. This synovial granulation tissue grows over the surface of the articular cartilage, and in so doing erodes the underlying matrix. If remission of the disease process occurs at this stage, then the resulting abnormal joint surfaces will eventually lead to the development of secondary osteoarthritic changes, irrespective of further exacerbations in rheumatoid disease. The development of synovial pannus is therefore of critical importance in the natural history of the disease process in a given joint, and the study of substances that are capable of producing a similar condition in experimental animals is of interest.

Jones and Carter[1,2] have shown that a proliferative synovitis can be induced in guinea pigs by the subcutaneous or intravenous injection of bacterial polysaccharide complexes. These findings raised the possibility of inducing a similar effect by the intra-articular injection of other polysaccharides the chemical nature of which was better understood, and consequently we have investigated the effect of intra-articular carrageenin, a polygalactose sulphate employed by other workers to produce connective tissue granulomas[3-5].

The polysaccharide solution in normal saline was sterilized by autoclaving, and then injected, under pentothal anæsthesia, through the antero-lateral approach into the femorotibial joints of young adult male rabbits. Following varying periods of time, the animals were killed by air injection and the synovial membranes dissected, fixed and stained. Cultures from all joints were made in Robertson's cooked meat or Brewer's thioglycollate media, so that all infected material could be discarded. The degree of synovial response to the polysaccharide was measured by the changes in either (*a*) the average number of cells per unit area or (*b*) the mitotic index, expressed as the number of mitoses/1,000 cells/per hr., following colchicine arrest.

After a single injection of 4 mgm. of carrageenin there is a wave of proliferation, the number of synovial cells per unit area being at a maximum on the tenth day, and then falling gradually. The effects of 0·2, 2·0 and 20 mgm. of polysaccharide per knee differed significantly in the degree of synovial proliferation. The effect of the highest concentration, however, was to elicit a much more marked influx of leucocytes and macrophages. In consequence, doses of between 2 and 3 mgm. of polysaccharide were used in further experiments, as with this dose-level proliferation was easily stimulated and wandering cells were at a minimum. Table 1 shows the variation of mitotic indices with time following a single intra-articular injection of 3 mgm. of carrageenin. The contralateral knee was used as a control, as no increase in mitotic index above normal limits was ever observed in these knees following injection of their treated pairs.

The results are expressed as the ratio of the treated mitotic index to the mean control mitotic index, which was 0·19 (standard error of mean 0·02).

Table 1

Days after injection	1	2	3	4	5
$\frac{\text{Treated}}{\text{Control}}$ mitotic index	4·3	30·9	29·3	21·9	17·0

Parallel investigations of the levels of ribonucleic acid, deoxyribonucleic acid, phosphocreatine, diphosphopyridine nucleotide and the *in vitro* uptake of oxygen, lactate production and glucose utilization showed that their maximum changes occurred at about the same period. These findings will be reported in full elsewhere.

When carrageenin was injected weekly for several weeks, the resulting massive synovial proliferation was accompanied by areas of early pannus formation caused by the erosion of the matrix of the articular cartilage by the synovial granulation tissue. In some rabbits, areas of small round cell accumulations were found in the proliferating villi, which resulted in a general histological picture very similar to that found in rheumatoid arthritis.

Other polysaccharides, with widely varying structures, were also compared for their effect upon synovial proliferation by the use of a balanced incomplete block design. Glycogen, fucoidin, chondroitin sulphate, dextrin, starch (soluble) and pectic acid were inactive but alginic acid and agar (Japanese) were significantly active, although less so than carrageenin. Prof. Choji Araki, Kyoto Technical University, Japan, very kindly supplied us with specimens of agarose and agaropectin, the two components of this agar. The former compound has little effect; but agaropectin is as active as carrageenin in the induction of synovial proliferation.

It is of interest that the two most active compounds both contain galactose. Carrageenin is a mixture of two polysaccharides, one containing sulphated galactose, the other sulphated galactose and 3 : 6-anhydro galactose chains. However, both constituents of agar contain galactose and 3 : 6-anhydro galactose[6], the active component, agaropectin, also containing small amounts of sulphate, glucuronic acid and pyruvic acid. It is unfortunate that little is known of the detailed structure of agaropectin.

Further work is in progress on the possible relationship between polysaccharide structure and the induction of synovial proliferation; but it is suggested that the experimental system reported here may have some use for the screening of therapeutic substances, such as steroids and their synthetic analogues, for anti-proliferative activity in synovial membrane.

We are indebted to Dr. E. Booth, Institute of Seaweed Research, Inveresk, and Dr. G. F. Springer, University of Pennsylvania, for gifts of fucoidin, to Dr. M. J. Egerton, Beecham Foods, Ltd., for the pectic acid used in this investigation, and to Dr. L. Stoloff, Marine Colloids, Inc., New York, for samples of carrageenin.

Anthelmintic Efficiency of Tetrachlorodifluoroethane against *Fasciola hepatica* in Sheep

CARBON tetrachloride and hexachloroethane are the most frequently used anthelmintics against *Fasciola hepatica*, the common liver fluke of sheep. These drugs are not always fully effective, and both at times produce severe toxic symptoms or death. Consequently, there remains the need for a safer and more effective agent active against liver fluke.

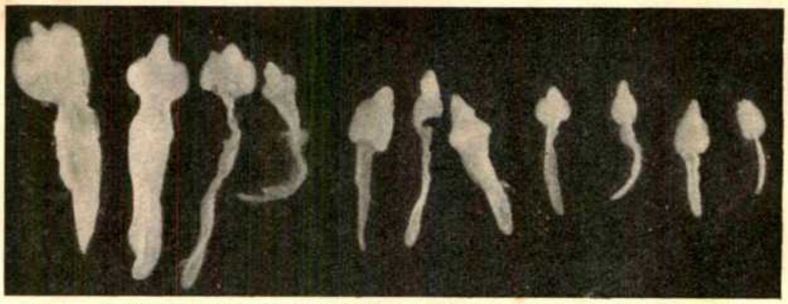

Fig. 1. Ascending necrosis of body of *F. hepatica* following treatment of sheep with 'Freon-112'

Inorganic[1,2] and organic[3,4] fluorine compounds have been shown to possess anthelmintic qualities, and it has been stated[5] that substitution of fluorine for chlorine in the methane series decreases toxicity.

Laboratory and field trials with 29 and 126 sheep, respectively, have shown that tetrachlorodifluoroethane ('Freon-112', E.I. du Pont de Nemours and Co. (Inc.), Delaware) is highly effective against mature *F. hepatica* at a dose-rate of 0·15 gm./lb. body-weight. Admixture with liquid paraffin to give a 50 per cent w/v mixture lowered the high freezing point and vapour pressure and gave a convenient solution for drenching. There was regularly a drop of 99–100 per cent in fæcal egg count. No living flukes were found in 29 previously infested sheep when the livers were examined at an abattoir 19 days after treatment. The drug was administered by intra-abomasal injection to two sheep and intrarumenally to four with similar results.

The effect on immature flukes was variable, and ranged from a complete kill to very little reduction in numbers. The low toxicity of 'Freon-112' will permit higher dose-rates to be employed in future trials of its efficiency in acute fasciolosis.

It has been reported[6] that doses of 2 gm./kgm. per day for up to 33 days did not produce liver damage in rats. No pathological changes were found in the liver, kidney or myocardium following single doses of 0·75 and 1·0 gm./lb. given orally to sheep 24 hr. before slaughter. No clinical symptoms of toxicity were observed in more than 150 sheep in 5 different locations treated with 'Freon-112'.

Three sheep were killed 24, 48 and 72 hr. respectively after treatment, and the flukes and eggs were collected. A very strong contraction of the uterus was observed, and it appeared that all eggs had been extruded from the flukes. In some cases the whole body except the oral and ventral suckers and the extreme oral portion of the fluke was necrotic (Fig. 1). In others most of the body had disintegrated and vanished, but the suckers and oral part were still active. This ascending necrosis of the fluke body has been observed by us at only one of many examinations following treatment of infested sheep with carbon tetrachloride. 'Freon-112' produced an adverse effect on the development and hatching of fluke eggs collected from the gall bladder and then incubated

Table 1. EFFECT OF 'FREON-112' ON FLUKE EGGS
Results given as percentage of total eggs examined after 2 weeks incubation

Sheep	Hr. after treatment	No development	Development started	Hatched
C 71	24	22	64	14
C 74	48	42	48	10
C 277	72	70	28	2

at 28° C. for 2 weeks. The intensity of this effect was increased with the length of the period during which the eggs had remained in the treated sheep (see Table 1). This is a useful residual effect.

Details of these experiments will be published in the *Australian Veterinary Journal*.

Subnormal Level of Carbonic Anhydrase in Blood of Carcinoma Patients?

It was shown in a recent paper[1] that the zinc content of whole blood in cases of very different cancers was subnormal (a mean decrease of about 20 per cent being found). Various metalloproteins are known which contain zinc as an essential part[2]. It seems wise to devote careful attention to carbonic anhydrase, a substance present in relatively large amounts in red blood corpuscles and described in detail by Keilin and Mann[3].

If, when using the preparation method of these authors quantitatively, it should turn out that the quantity of zinc present in whole blood equals the quantity of zinc present in carbonic anhydrase prepared from this blood, one might characterize carcinomas by a subnormal level of carbonic anhydrase. Table 1 shows results of determinations of zinc carried out by analysing various blood fractions which Dr. H. J. van den Berg was kind enough to prepare. After centrifuging off the serum, hæmolysing the erythrocytes and precipitating hæmoglobin with ethyl alcohol and chloroform, the remaining carbonic anhydrase was precipitated with lead acetate. The determination of zinc was carried out spectrochemically[4].

According to Keilin and Mann, 50–60 per cent of carbonic anhydrase is occluded during the precipitation of hæmoglobin, which can also be seen from Table 1.

Table 1

	Weight (gm.)	Zinc content (p.p.m.)	Weight of zinc (gm.)	Weight of zinc (gm.)
Whole blood	201	5·7		0·00115
Plasma	102	0·9*	0 000097	
Leucocytes + water	1 25	25	0·000031	
Erythrocytes	105	9 9	0 00104	
		Total	0 00117	0 00115
Erythrocytes	105	9 9		0·00104
Hæmoglobin:				
First fraction	25	13·6	0 00034	
Second fraction	3	43 8	0 00013	
Lead precipitate	4	136	0 00054	
		Total	0·00101	0 00104

The lead precipitate cannot be decomposed without destroying the protein. For this reason the clear solution of carbonic anhydrase was dialysed against water, whereby according to Vikbladh[5] once again zinc ("loosely-bound zinc") is lost up to about 70 per cent. The dialysed solution, free from chloroform, alcohol and salts, was dried *in vacuo* at a low temperature (about 5° C.).

Table 2 shows the zinc balance.

Table 2

	Mgm. zinc
100 ml. of whole blood contains	0·65
The serum fraction contains	0·1
remainder	0·55
60 per cent loss owing to co-precipitation with hæmoglobin remainder	0·22
70 per cent loss owing to loosely bound zinc being dialysed remainder	0·07
45 mgm. of impure carbonic anhydrase (containing 0·15 per cent zinc) prepared from 100 ml. of whole blood contain also	0 07

It appeared to be possible to increase the purity of the product: its zinc content varied between 0·25 and 0·35 per cent (Keilin and Mann, 0·33 per cent; other investigators, between 0·2 and 0·32 per cent).

The properties of the preparations are as follows:

(1) One of them appeared to contain 14·1 per cent nitrogen (Dr. F. J. Spruit); Keilin and Mann mention a value of 14·95 per cent.

(2) Paper electrophoresis (Dr. J. Voogd) showed the existence of two protein fractions (see also Bate-Smith[6]). The main fraction appeared to change proportionally with time into the second fraction, which has a smaller rate of migration and probably a larger molecular weight. This change appeared to be closely related to the zinc content of the carbonic anhydrase. It is known that zinc facilitates the formation of larger molecules. On the other hand, this effect of change was shown to be absent when all manipulations were carried out in the absence of oxygen. It is therefore probable that carbonic anhydrase is sensitive to oxygen.

(3) Semi-quantitative spectrochemical analyses showed the following results: 0·2–0·8 per cent potassium and also sodium; 0·7 per cent calcium; 0·1–0·2 per cent phosphorus; 0·05–0·1 per cent magnesium; 0·01–0·03 per cent copper; 0·01 per cent iron and 0·001 per cent manganese (a preparation made from ox blood appeared to contain twice as much of these elements, but only 8 per cent nitrogen).

The following hypothesis seems worth serious consideration. A subnormal level of carbonic anhydrase in carcinoma cases can have a serious effect on the metabolism. The transport of carbon dioxide can be hindered, and this is certainly the case in a tumour resulting in a process of fermentation[7]. Therefore in my opinion it would be worthwhile to study intensively the anti-carcinogenic activity of carbonic anhydrase.

Thanks are due to Dr. H. J. van den Berg, Dr. F. J. Spruit and Dr. J. Voogd for their valuable help as well as to Miss H. Savenije for her careful determinations of zinc.

RADIOBIOLOGY

Inability of Thiotaurine to protect Mice against Ionizing Radiation

One of the theories proposed for explaining the protective role of certain substances on animals submitted to a lethal dose of ionizing radiation involves the capture of free radicals by the protective compound (scavenger action). As a consequence of this process the compound is chemically modified in the biological structures where it happens to be, which then survive the irradiation. If such a theory is correct a certain degree of correlation would be expected between the protecting activity of a substance and its lability towards radiation, unless a catalytic mechanism is involved.

Cystamine, one of the best-known biological protectors against radiation[1], is relatively resistant to radiation in solution. A low percentage of degradation products has been detected only after heavy irradiation[2]. Thiotaurine, a metabolic product of cystine and cystamine, has been recently found more sensitive than cystamine to an equal amount of X- and γ-rays[3].

The validity of the presumed correlation between radiochemical degradation and biological protection has been investigated by comparing the protective effects of thiotaurine and cystamine against a lethal dose of X-rays on mice. Three groups of 15 white male mice of the Swiss strain weighing 20 gm. were placed in a wooden box with a 'Perspex' cover in mixed groups of 15 animals and exposed to a dose of 600 r. in the space of 15 min. One group was the control: another was injected intraperitoneally with half the *LD*50 of cysteamine neutralized with *N* hydrochloric acid (cysteamine and cystamine have equal protective power[1]), 15 min. before irradiation. The third group received half the *LD*50 of thiotaurine[4] in the place of cysteamine. Under our conditions the *LD*50 for cysteamine and thiotaurine were respectively 0·27 gm./kgm. and 3·52 gm./kgm., that is, thiotaurine is tolerated much more than cysteamine. On the molar base, the thiotaurine injected represents an amount seven times higher than that of cysteamine.

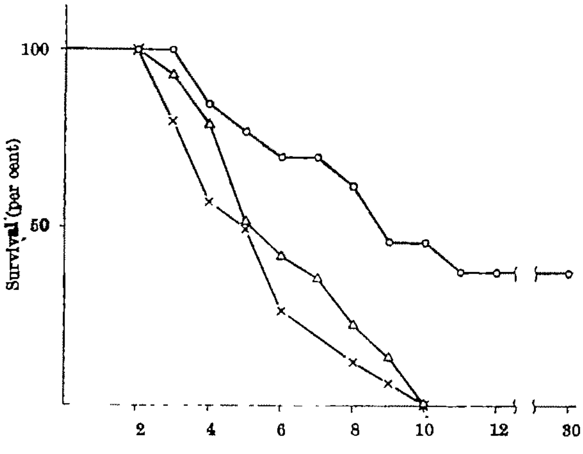

Fig. 1. Effect of cysteamine and thiotaurine on the survival of mice after exposure to X-rays. ×, 600 r.; ○, 600 r. and half the *LD*50 of cysteamine (0·135 gm./kgm.); △, 600 r. and half the *LD*50 of thiotaurine (1·760 gm./kgm.)

The results are shown in Fig. 1. It may be seen that all the thiotaurine-treated mice died within 10 days of irradiation, while little less than 50 per cent of the cysteamine-injected mice are still alive. This clear-cut result excludes any possible role of thiotaurine as a protective agent despite its relative lability towards radiations, and despite the large dose injected. This finding suggests that the correlation of the radiochemical degradation of a substance with its biological protective power is untenable. Moreover, it supports the view of those who believe that the 'scavenging action' plays only a minor part in the mechanism of the chemical protection[5].

Divergence between Lethal Doses and Sterilizing Doses of X-Rays with Progressive Development in *Habrobracon* Females

In the present work I have determined the weakest link in an insect life-cycle and related this to the quantitative differences between the sterility and lethality doses when virgin females were irradiated at various developmental stages. The wasp used is known in genetic literature as *Habrobracon juglandis* (Ashmead). The females were chosen since it was believed that a non-sterile female would normally live and copulate with a son and afterwards produce both males and females. Critical stages for exposure were selected at significant changes in somatic and/or gonadic differentiation.

The stock, derived from a mother–son mating in 1952 of wild type Whiting stock No. 33, has maintained excellent egg production and viability for more than 270 generations. The small braconid wasp parasitizes various lepidopteran larvæ. *Ephestia kuehniella* (Zeller) caterpillars are the standard host employed. *Habrobracon* females usually mate once. Fertilized eggs develop into diploid females; unfertilized eggs develop parthenogenetically into haploid males. All rearing was done at 30° C., and samples of 20 wasps per stage were used.

Eggs or immature forms of known age were irradiated at the Marine Biological Laboratory, Woods Hole, Massachusetts (25 m.amp., 250 kV. peak, filtration ≡ 0·2 mm. copper). A constant target–tube distance of 23 cm. was maintained to produce 600 r./min.

Females were considered sterile if oviposition failed; or in the case of forms more than 6 days old, if oviposition ceased after the deposit of eggs preformed at the time of irradiation. The lethal dose is considered to be that X-ray exposure which prevented eclosion; consequently, death could occur between

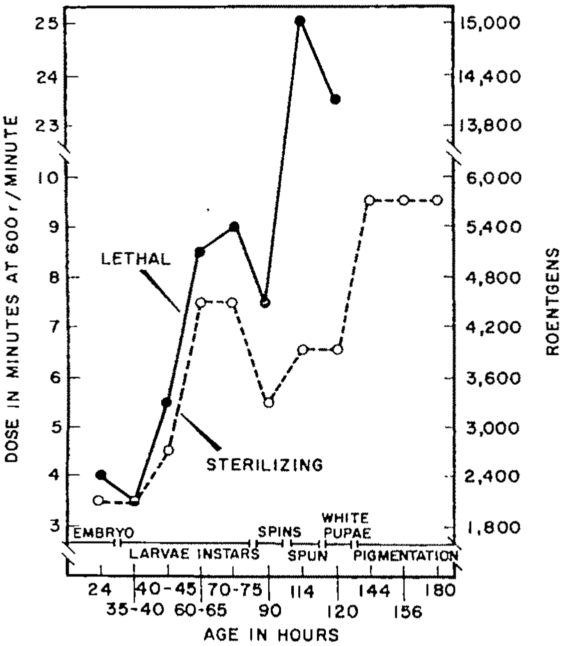

Fig. 1. Sterilizing and lethal X-ray doses for significant developmental stages in the life-cycle of *Habrobracon juglandis* (Ashmead)

treatment and pre-eclosion, usually at some developmental crisis.

Specific controls were not used. Stock performance during the experiments and its subsequent performance are sufficient evidence of an unaltered and high reproductive capacity of untreated wasps.

The pattern of radiation-induced effects is shown in Fig. 1 for most of the life-cycle to demonstrate the divergence between sterilizing and lethal doses. At stages earlier than shown, the gonad is no more radiosensitive than the soma, since females developing after doses at the lethal threshold are as fertile as unexposed wasps. Very little radiation, 100–200 r., kills 1–3 hr. embryos. This, the weakest link in the life-cycle, is the time at which primitive germ cells differentiate and begin posterior migration. These cells are not seriously influenced by irradiation up to the dose that prohibits hatching. Selective irradiation of the posterior pole was not successful in destroying this cell population. The bulk of the egg (9–13 hr. old) was shielded with lead so that only the posterior pole was irradiated with 170 r./min. Samples were exposed from 1 to 90 min. The 10-min. exposure appeared to be lethal.

The curve (Fig. 1) for increased radiosensitivity does not progress smoothly. Biological considerations are offered in explanation. During early larval life, all basic organ systems differentiate from embryonic germ layers, but the business of ingestion seems of chief concern during the instars. Then at 90 hr. there is a highly active physiological condition in preparation for spinning, as well as critical internal histological changes. Then, somatic radioresistance increases appreciably at the postmeconium stage (114 hr.), followed by a drop back toward sensitivity in white pupæ. Compared with older forms which withstand up to 300,000 r. (ref. 2), white pupæ are very sensitive probably because muscle and other tissues are forming while the fat body, the predominant tissue, is resorbed. Active cell division and physiology could account for the radiosensitivity. Thus, the over-all pattern of effects appears consistent with a modernized version of the radiobiological 'law' of Bergonie and Tribondeau (see ref. 4) which stated that sensitivity of cells to radiation depends upon their reproductive activity and degree of differentiation.

I thank Dr. D. S. Grosch for his help and guidance during this investigation and preparation of this communication. The work was carried out as part of the requirement for a Ph.D. thesis at North Carolina State College, Raleigh, North Carolina.

Changes in Structure of a Periclinal Chromosomal Chimera of Apple following X-Irradiation

THREE types of periclinal chromosomal chimeras in apple have been found in Nature[1-3]. Their apical meristems are characterized by one, two or three layers of diploid cells over tetraploid interior cells. Plants with one diploid layer (designated 2–4–4–4) produce diploid gametes, but the others (2–2–4–4 and 2–2–2–4) produce haploid gametes[3]. Since 2–4–4–4 chimeras are a source of diploid gametes for use in breeding polyploid apples, it would be desirable to produce this chimera in varieties in which only the other types have been found. X-rays have been shown to alter the structure of a periclinal chimera in carnation[4]. The effects of X-radiation on a 2–2–4–4 chimera of apple, 'Giant Spy (Loop)'[1-3,5], has been reported as an abstract[6] and are here described in more detail.

Dormant one-year-old shoots from trees seven to twenty years old of 'Giant Spy (Loop)' apple were irradiated in February, 1957, at Brookhaven National Laboratory, Upton, New York. A General Electric Maxitron X-ray machine was operated at 250 kVp. and 30 m.amp. with 1 mm. aluminium filtration to deliver doses of 3,000 r. A single layer of scions was exposed at one time and only those buds which occurred on the exposed side of the shoot were selected to grow. Treated and control scions were bench-grafted to apple seedlings and the plants forced in the greenhouse.

Buds just starting to grow were fixed in Randolph's modification of Navashin's fluid[7]. Slides of about 40 buds were prepared and stained in safranin and fast green[7] or in crystal violet[1].

The remaining plants were grown for two years. All trees sampled had grown from the irradiated scion and not from the rootstock. The terminal portion of each main branch (1–5 per tree) of 38 treated and 6 control trees was cut in the spring of 1959 and forced in water in the greenhouse. About 270 growing buds were collected and processed as described by Blaser and Einset[1].

The distribution of diploid and tetraploid cells, which were distinguished by the comparative size of division figures, chiefly metaphase plates[1], was noted in the apical meristem, deeper stem tissues and young leaves of 2–15 buds per tree. Shoot tips with the constitution 2–2–4–4 and 2–2–2–4 could be distinguished only by comparison of figures in the apical meristem itself. At least one shoot tip with a definite determination of ploidy of layers was necessary to identify the type of chimera present.

Buds from the trees which were the source of the irradiated material were found to be 2–2–4–4 chimeras either in the present or earlier[3] studies. The chromosomal constitution of buds from control plants was 2–2–4–4.

Buds collected two weeks after forcing of the irradiated bench-grafted scions showed a pattern of radiation damage similar to that found in other irradiated apple shoot apices[7]. The walls, cytoplasm and nucleus of cells of the first layer generally stained like those of normal meristematic cells. Occasionally a few cells showed collapse or 'absence' of the protoplast. Many deeper cells in the central area of the tunica and corpus showed heavily stained walls, collapsed cytoplasm and disorganized nucleus, or protoplast so lightly stained that the cell appeared 'empty'. The axillary meristems had a pattern of radiation damage similar to that of the apical meristem.

In about one-third of the apices collected 2–6 weeks after forcing where the damaged area was still conspicuous, division figures were found in living cells near the damaged cells, both in the first layer and, more frequently, in the deeper cells.

The chromosomal constitution of branched or unbranched shoots which had grown for two years after irradiation of the original bud is presented in Table 1. The high frequency (33 out of 41 surviving buds) of types different from the one irradiated makes it probable that these have occurred as a result of shifting of layers during the re-organization of the shoot apex after radiation damage, and not as a result of changes in ploidy induced by radiation. Divisions observed in cells near the area of damaged cells suggest that a shoot apex may be formed from cells peripheral to the injury, either in the terminal or axillary meristems. Unfortunately, no stages in the re-organization of the apex were found, perhaps due to too widely spaced collections. The formation of a shoot primarily from the inner tetraploid cells with the original surface cells propagating themselves as a single diploid layer, which produces a 2–4–4–4 type, was much less frequent than formation of a new shoot from the upper diploid layers, which produces 2–2–2–4 and diploid shoots.

Table 1. CHROMOSOMAL CONSTITUTION OF TWO-YEAR-OLD SHOOTS EACH FROM ONE IRRADIATED BUD OF 'GIANT SPY (LOOP)' (2–2–4–4)
Figures refer to the number of shoots of each type.

2–4–4–4	2–2–4–4	2–2–2–4	2–2–2–2	2–2–4–4 and 2–2–2–4	2–2–4–4 and 2–2–2–2	2–2–2–4 and 2–2–2–2
3	8	10	12	3	1	4

Eight shoots were not uniform in type (Table 1). The chromosomal constitution of buds in four instances was consistent within a branch, but in four others variable within a branch. The buds themselves appeared to be of one type. This lack of uniformity may result from the segregation of chimeral or diploid buds from different sectors of some reorganized apices. The instability of 2–2–2–4 chimeras may also be related to the slight tendency of natural 2–2–2–4 chimeras to produce diploid buds[3].

The pattern of radiation sensitivity of cells in the apple shoot apex, as indicated by their survival, is similar whether a wholly diploid shoot or a chimeral one is irradiated with a dose semi-lethal to the bud[7]. Sensitivity to these doses seems to be related to the position of the cells in the meristem rather than to the ploidy of those cells.

X-irradiation seems to be a tool for producing from 2–2–4–4 chimeras, which produce haploid gametes, 2–4–4–4 chimeras, which may be expected, barring chromosomal or genic changes, to produce diploid gametes for use in breeding polyploid apples.

BIOLOGY

Autocatalytic Particles and Steady States

THERE are several phenomena in microbial heredity which are suggestive of cytoplasmic inheritance in that a particular self-perpetuating state can be induced rapidly in a large majority of the population by relatively simple changes in the growth conditions. These include long-term adaptation in yeast[1], auto-adaptation in bacteria[2], and the adaptive formation of β-galactosidose in *Escherichia coli* grown at maintenance-levels of inducer[3].

The first of these systems to be analysed in detail with respect to the points of interest here was long-term adaptation. One question which was asked was whether the ability of the cells of slow fermenters to metabolize galactose depends on the presence in these cells of some kind of autocatalytic particles. From an analysis of the kinetics of the loss during growth on galactose-free medium of the capacity to form galactose-positive colonies, it was deduced that this was indeed the case, and that a small number of such particles (of the order of one per cell) was necessary to function autocatalytically[4].

Several models were proposed for the mechanism of the autocatalysis, some of which did, and others of which did not, require that the particles be self-duplicating[5,6]. These have all been superseded by the recent detailed analysis of the β-galactosidose system of *Escherichia coli*[3,7], in which it was possible to equate the autocatalytic particle with the β-galactosidose permease.

There is one point in the discussion of these results which should be clarified. The 'autocatalytic particle' hypothesis originally considered for long-term adaptation is of course logically valueless unless one can imagine some alternative model. The alternative generally considered is an aparticulate model depending on the existence of multiple steady states. There has been some disagreement in recent years[8] as to whether these two alternatives are really distinct. It has been implied that the 'steady state' hypothesis is simply a mathematical description which can be applied to autocatalytic particles among other things[9]. This is presumably also the point of view of Cohn and Horibata[7], since they interpret their results, which certainly involve autocatalytic particles, to be an example of the steady-state model.

I wish to point out here: (1) that there is a logical distinction between autocatalytic particle models and stable steady-state models; and (2) that no example of the latter has as yet been provided.

Steady states. Consider a cell which contains n chemical species involved in related reactions. Let c be the concentration of the ith species. Then we have, in general, a system of n simultaneous differential equations of the form:

$$\frac{dc_i}{dt} = f_i\,(c_1\, c_2 - - - - c_n)$$

A stable steady state is said to exist at some set of values $(C_1, C_2 - - - C_n)$ of the concentrations if two conditions are satisfied: (1) $f_i\,(C_1, C_2 \ldots C_n) = 0$ for all i; (2) the system will tend to return to the steady state following a sufficiently small displacement in any direction from the steady-state values.

It is easy to find examples of such steady state. It is also easy to construct examples in which more than one solution exists for condition (1). Condition (2) is also easy to satisfy for a single solution; but it is not satisfied by most of the systems with multiple solutions which have been proposed in more or less mathematical detail by various authors[10,11].

Condition (2) is, however, critical. Without it, the steady state is unstable in the same sense that the equilibrium of a cone balanced on its vertex is unstable. Any small fluctuation will cause it to diverge permanently from the steady state in question.

Autocatalytic particles and unstable steady states. The autocatalytic particle hypothesis can be defined as follows. There is some subcellular particle X with the properties that: (*a*) A cell with at least one particle of X will synthesize more such particles during growth; (*b*) a cell with no such particles will not form any.

Such a system will generally have at least two steady states. One of these (at $X = 0$) is, however, unstable. The most basic distinction is therefore between stable and unstable steady states, the autocatalytic particle hypothesis being a special case of the latter. The mechanism of autocatalysis is irrelevant in the context.

Condition (*b*) cannot of course be taken literally, since any molecular event must have some non-zero probability. In practice, what is meant is that the probability of forming a particle during one cell division cycle is much less than one. The genes themselves approximate this rule well enough to have allowed the construction of the science of genetics.

Stable steady states could in principle be maintained indefinitely in growing, well-mixed tubs of protoplasm which are never subdivided into smaller isolated regions. The 'hereditary' character of unstable steady states, on the other hand, depends completely on the fact that the cell has a finite size. Each cell division creates a certain possibility for the occurrence of occasional cells with a large disparity in the numbers or kinds of certain critical molecules, and one such fluctuation has occurred, its results being confined to the progeny of the cell in which it took place. The process is reminiscent of genetic drift or gene fixation; or, more properly, these phenomena are themselves examples of unstable steady states within a population rather than within a cell.

Another type of unstable state may explain some of the antigenic changes in *Paramecium*, for which Delbrück's[10] steady-state hypothesis was originally proposed. These are states which are not steady at all, but for which the change from one state to another is sufficiently slow to require many cell generations. The continuation of such states for a limited number of generations does not depend on finite cell size, and they cannot be perpetuated indefinitely even among sublines continually selected as being apparently in the original state.

Chromosome Numbers of Slugs

CHROMOSOME numbers are becoming increasingly part of the taxonomic descriptions of animal and plant species.

Very few figures are known for the slugs, the collective name given to members of the three families of almost shell-less pulmonate molluscs which occur in Britain. Some pulmonate species have been examined in France and Switzerland by M. and J. L. Perrot[1-3], and the comparison of their results with mine, given in Table 1, shows that the number of chromosomes is the same for British and Continental samples. No evidence has been found of chromosome races, as in the populations of *Sorex araneus* studied by Ford *et al.*[4].

Chromosome counts were made at the first meiotic prophase and metaphase stages of spermatogenesis, and also the mitotic metaphases found in ovotestes of mature or nearly mature animals. The ovotestis was fixed in alcohol-acetic, teased to separate the cells, and stained and squashed in aceto-orcein.

The taxonomic arrangement of this list is that of Quick[5], containing the alteration of *Limax arborum* Bouchard-Chantereaux to *Lehmannia marginata* Muller; the name *Lehmannia* having been used generically by Malm in 1868. Cytotaxonomy fully supports the withdrawal of this species from the genus *Limax*; a change made on the structure of the radula. *Limax tenellus* seems to correspond more closely with *Lehmannia marginata* in chromosome number than with the other three British species of *Limax*. Intrageneric variation in chromosome number in the genus *Arion* emphasizes the close relationship between *A. ater* L. and *A. rufus* L.; considered as subspecies by Cain and Williamson[6].

Little or no variation has been found within the other genera, and the number of chromosomes cannot

An Apparatus for Panning in Cine Micrography

IN ciné micrography it has not been possible to vary the viewpoint or introduce variety by devices equivalent to 'panning' or 'tracking' in ordinary ciné photography. This limitation makes it difficult to show some aspects of a microscopical field which demand the use of a moving stage.

The movement of the usual rack and pinion of the mechanical stage of a microscope, when enlarged 300–400 times on the film before projection, is so irregular owing to the backlash and the tremor of the operator's hand and the need for changing the grip that it is quite unacceptable.

After a number of attempts, a successful apparatus has been made which combines the principles used in the De Fonbrune and the Singer micromanipulators. This gives smooth control of movement in both directions separately or combined.

The arrangement consists of two pieces of aluminium plate, the bottom one bolted by two easily detachable brass brackets to the microscope stage, the upper one stuck to it with petroleum jelly.

The lower plate has a central hole over the condenser lens, and the upper plate has an excentric opening which overlaps the condenser hole by about 2 cm. When arranged ready for use, the upper plate projects for about 2 cm. beyond the lower, both to the left and forward.

Two small syringes with metal plungers are mounted horizontally and at right angles to each other beside the stage. Slots cut in the heads of the plungers rest against the upper, moving plate. This gives both a certain grip and at the same time permits automatic re-arrangement of one syringe as the other is in use. Both syringes are carried at the correct height by metal rods on top of which are spring clips. The rod which provides anterior–posterior movement is placed off-centre to clear the beam of light from the lamp. A plastic or wooden base with stops for the foot of the stand is also required. The supporting rods are screwed to this.

Each of the syringes is connected to another syringe by narrow rubber pressure tubing. Plastic tubing is too rigid in the wall and too springy to be a satisfactory alternative. The syringes on the free end of the rubber tubes are pressed to drive the stage. They need not be the same size as the others, but no advantage appeared to be derived from using smaller syringes as no gearing ratio was necessary in practice.

In use, the slide to be filmed is placed on the upper sliding plate. The pair of syringes on the free ends of the tubing are held between the fingers of the left hand and their plungers compressed with the thumb; one alone, or both, may be used to give movements in two directions at right angles or diagonal movement. The right hand is available for the normal controls of the microscope.

No special return mechanism is provided. At the end of the run, the sliding plate is simply pushed back to the starting position.

GENETICS

Position of the Gene determining the Diploid-like Meiotic Behaviour of Wheat

COMMON wheat (*Triticum aestivum* $2n = 6x = 42$) has attained the hexaploid condition by the combination of the full chromosome complements of the three diploid species *Triticum monococcum*, *Aegilops speltoides* and *Aegilops squarrosa*[1-3]. However, at meiosis in *T. aestivum*, despite the close genetical and cytological relationships of its diploid ancestors, each chromosome pairs with its fully homologous partner and only bivalents are formed. There is no pairing between corresponding, homœologous, chromosomes derived from different diploid ancestors, although considerable similarity in the genetical activities of homœologues still remains[4].

Riley and Chapman[5] showed that homœologous pairing was no longer precluded in the absence of a particular chromosome, the *HH* chromosome, from 20-chromosome haploids and 40-chromosome nullisomics of the variety Holdfast. Thus the control of the diploid-like, bivalent-forming, meiotic regime in wheat can be ascribed to a gene-system on this chromosome.

Simultaneously, Sears and Okamoto[6] interpreted the high incidence of meiotic pairing in hybrids between *T. monococcum* and *T. aestivum* variety Chinese Spring, deficient for chromosome V, to mean that the regular meiotic behaviour of wheat was due to the activity of this chromosome.

The deficiency of the *HH* chromosome in nullisomics of Holdfast, and of chromosome V in nullisomics of Chinese Spring, results in equivalent modifications of external plant morphology. Also, both chromosomes are alike in structure, being among the largest in their respective complements, and having one arm more than twice the length of the other. Thus it seems likely that they are homologous, but for an understanding of the cytogenetic structure of wheat it is necessary to determine their exact relationships.

For this purpose hybrids were made between 41-chromosome plants of Holdfast, with the *HH* chromosome monosomic, and plants of Chinese Spring in which chromosome V was represented by a pair of telocentrics for the long arm and the other arm was completely deficient. At meiosis, the 41-chromosome hybrids, which had not received the unpaired *HH* chromosome from Holdfast, had 20 normal bivalents, and the telocentric of chromosome V, from Chinese Spring, was a univalent. Consequently, V and *HH* must be fully homologous chromosomes and investigation of the two varieties concerned has revealed the same genetic control of meiosis.

Since the absence of chromosome V results in homœologous pairing, there is evidently no independent control, on any other chromosome, capable of causing the meiotic isolation of chromosomes of the different basic diploid sets. However, it might have been that the gene on chromosome V was part of a complementary system, the removal of any part of which would result in the breakdown of the normal regulation of meiosis. To test this a series of 21 wheat – rye hybrids was made in which hybrids were deficient, in turn, for each of the 21 chromosomes of wheat. The hybrids were produced by pollinating with rye (*Secale cereale* $2n = 14$) the 21 lines of Chinese Spring wheat which were monosomic for chromosomes I–XXI. Use was made of the 27-chromosome hybrids to which the chromosome which was unpaired in the monosomic wheat parent had not been transmitted.

Table 1. MEAN CHROMOSOME PAIRING AT FIRST METAPHASE OF MEIOSIS IN NORMAL HYBRIDS OF *T. aestivum* × *S. cereale* AND IN THE 21 HYBRIDS DEFICIENT, IN TURN, FOR EACH WHEAT CHROMOSOME

Riley, Chapman and Kimber[7] have already shown that there is much higher pairing in wheat – rye hybrids, deficient in chromosome V, than in normal, euploid hybrids. The extra pairing results from homœologous associations within the wheat complement as well as from associations of wheat and rye chromosomes. It may, therefore, be expected that the absence from a wheat – rye hybrid of any other wheat chromosome, carrying a gene similar in effect to that on chromosome V, would cause similarly altered meiotic pairing.

First metaphase of meiosis was examined in 50 pollen mother cells from each of at least two plants of every type of chromosome-deficient hybrid, as well as in six euploid hybrid controls (Table 1). Hybrids deficient for chromosome V had much higher pairing than euploid hybrids, and higher pairing than hybrids deficient for any other chromosome. The mean number of trivalents in V-deficient hybrids exceeded the mean number of bivalents in most other lines, and the number of bivalents was more than three times greater in the absence of V than in any other condition. There can be no doubt that the deficiency of chromosome V is unique in its effect on meiotic behaviour, for the differences among all the other hybrids are of an order which may be ascribed to environmental effects.

Thus the meiotic isolation of corresponding chromosomes of the different genomes of wheat is due to the activity of chromosome V alone. It has also been shown that this activity is due to the long arm of the chromosome[5], but there is no evidence concerning the number of loci involved.

However, the localization is consistent with the notion that a single mutant gene, having the observed effect on meiosis, was selected because of its influence on fertility and genetic stability, early in the development of polyploidy in *Triticum*. The selection of a single powerful, cytologically stabilizing, mutant would presumably be rapid and efficient. By contrast, it is difficult to visualize the processes by which, as required by the discarded alternative hypothesis, a system of complementary genes controlling the diploid-like meiosis could have evolved. This would have required the independent selective incorporation of a number of mutually dependent genes, each of which was vital for the occurrence of regular meiotic behaviour with its attendant reproductive stability.

Nevertheless, genes other than the one at the critical locus on chromosome V must influence the meiotic behaviour of wheat, and some may modify in one direction or another the regular, bivalent-forming, pattern Meiosis in wheat is, therefore, delicately balanced between excessive pairing leading to multivalent formation and genetic instability, and failure of pairing, leading to univalent formation and aneuploidy. This balance has made possible the simultaneous occurrence of pronounced genetical triplication with high fertility and stable inheritance.

Experimentally Induced Inter-bivalent Redistribution of Chiasmata in *Delphinium*

THE non-random distribution of chiasmata in a bivalent due to the occurrence of interference is well known. It has been suggested by some authors that the inter-bivalent distribution of chiasmata may also not be independently determined. Correlation studies on chiasma frequencies have demonstrated competition for chiasmata between bivalents in some organisms but not in others[1,2]. In the course of investigations on the cytogenetic effects of ionizing radiations on plants, we have been able to affect changes of chiasma frequency in one group of chromosomes in the nucleus and observe the reaction of the other group to this experimentally induced condition.

Dry seeds of *Delphinium ajacis* variety 'Comet' were irradiated with an X-ray dose of 15,000 r. (50 kV.). The X_1 plants raised from these showed certain cytological characteristics which appeared to be of interest. Apart from gross structural changes in the chromosomes of some of the plants which indicate interchange multiple associations, several others were characterized by disturbed chromosome pairing and chiasma frequencies. Observations on the control plants show that eight bivalents are regularly formed in most of their pollen mother-cells, a few of the cells showing seven pairs and two univalents. Since two of the eight chromosome pairs are considerably larger than others, they can be easily identified, and they appear mostly as ring bivalents at metaphase with two terminal or sub-terminal chiasmata; the remaining six smaller pairs appear in most pollen mother-cells as one ring, and five rods or all rods, each with a sub-terminal or nearly terminal chiasma. The two univalents whenever present are members of one of the smaller pairs of chromosomes.

The plants from the seeds treated with radiation differ from the controls in having two or more univalents present in many of their pollen mother-cells. Both the large and the small group chromosomes may appear as univalents, quite often in the same pollen mother-cell; their number varies from plant to plant as shown in Table 1. Also shown are observations on each of the 5 control and 9 X_1 plants with regard to the mean number of ring bivalents found in their pollen mother-cells. The proportion of rings formed by the large and small chromosomes respectively has been indicated separately.

The results for X_1 plants have been arranged in an order which helps to emphasize the relationship that appears to exist between the frequencies of the large and the small ring bivalents. The results show clearly that as the frequency of ring bivalents formed by the large chromosomes is reduced due to their occurrence as univalents or rod bivalents, the frequency of such configurations formed by the smaller chromosomes is either increased significantly beyond the level in the control material, as in plants 4, 6 and 11, or is maintained at a similar level, as in plants 7, 8 and 9, in spite of the fact that a number of small chromosomes also appear as univalents. In some of these plants it is quite common to find pollen mother-cells in which the two large ring bivalents were replaced by a similar number of small ring bivalents. The only exception is provided by plant 12, in which the frequencies of both the large and the small rings are reduced.

Although both chromosome pairing as well as chiasma formation and terminalization are known to be genotypically controlled, it is obvious that neither

the occurrence of univalents nor the changes in chiasma frequency in the plants from X-irradiated seeds are genetically determined. Not only do the univalents occur in most of the X_1 plants but also their frequency shows great variation; and the smaller chromosomes, which outnumber the larger ones, are affected more often as would be expected on a random basis. It may be supposed that the X-irradiation of seeds induces structural changes in a number of chromosomes at random, affecting their pairing at pachytene and formation of chiasmata. The re-distribution of chiasmata described above occurs probably in those plants in which a number of smaller chromosomes have escaped damage.

The non-random distribution of chiasmata, for which evidence has been presented here, emphasizes the co-ordination existing in the control of chiasma formation in different chromosomes in the nucleus. How this control is exercised is not very evident. The chromosome changes induced by radiation, which result in the re-distribution of chiasmata, also stress the evolutionary significance of spontaneously occurring structural changes of chromosomes. Not only may many of these changes give rise to new variation by producing effects which simulate point mutations, but also they may release latent variability through re-distribution of points of crossing-over. The importance of such re-distribution resulting from a different kind of agency, in relation to natural selection, has been discussed by Mather and Harrison[4].

We are grateful to Dr. B. P. Pal and Dr. A. B. Joshi for their interest and encouragement. Thanks are also due to Dr. M. S. Swaminathan for discussing the results with us.

VIROLOGY

Somatic Antigen 15 as a Precursor of Antigen 34 in *Salmonella*

PHAGE ε^{34} is a temperate phage produced by group E_3 *Salmonellae* with O antigens (3), (15), 34 and capable of converting group E_2 *Salmonella* (O antigens 3, 15) to group E_3 *Salmonella* (O antigens (3), (15), 34) by lysogenization[1–5]. The formation of antigen 34 is accompanied by partial loss of antigens 3 and 15[5], suggesting a close relationship between antigens 34 and 3 or 15. The experiments described here indicate that antigen 15 is a precursor of antigen 34.

Group E_1 *Salmonellae* with O antigens 3, 10 do not adsorb phage ε^{34}. However, the possibility of infecting group E_1 cells directly with phage ε^{34} is suggested by the experiments of Uetake, Luria and Burrous[6]. They reported that when *Salmonella anatum* (group E_1, O antigens 3, 10) is infected with phage ε^{15}, antigen 15 and receptors for phage ε^{34} appear within a few minutes, the cells which survive infection segregate phage-carrier and non-carrier cells in their progeny, and in the non-carrier segregants the changes in antigenic structure and in phage receptors initiated by phage infection persist for several generations. Therefore, if the non-carrier progenies with receptors for ε^{34} are infected with ε^{34}, *S. anatum* might probably be lysogenized with ε^{34} without carrying ε^{15}. This proved true in the following experiments.

Cells of *S. anatum* were infected with phage ε^{15} at a multiplicity of 3·6, and progenies of the cells, which survived infection with ε^{15}, were infected with another phage ε^{34} 3 hr. after ε^{15}-infection, at which time about 90 per cent of cells were not carrying ε^{15}. Approximately 87 per cent of cells survived infection with ε^{34}. Among the survivors, 82 per cent proved to produce ε^{34}, but most of them not to produce ε^{15} by replica plating[6,7]. By agglutination and absorption tests these ε^{34}-producing cells ($= A(\varepsilon^{34})$) proved to possess somatic antigen 3, 10, the same structure as that of *S. anatum*. Most important is that they do not possess antigen 34. They are sensitive to phage ε^{15} and its mutants, while they adsorb neither phage ε^{34} nor its mutants, being similar to *S. anatum*. The only difference from *S. anatum* is in resistance to phage C_{341} to which *S. anatum* is sensitive, although $A(\varepsilon^{34})$ cells still adsorb phage C_{341} at an adsorption-rate constant of $3 \cdot 1 \times 10^{-9}$ ml. per min. (Table 1). When $A(\varepsilon^{34})$ cells were infected with ε^{15}, both antigens 15 and 34 appeared within several minutes in infected cells.

Among the above, most remarkable are the findings that $A(\varepsilon^{34})$ cells do not form antigen 34 irrespective of presence of prophage ε^{34}, which always leads to the formation of antigen 34 when it infects 3, 15 cells of group E_2, and that antigen 34 appears when $A(\varepsilon^{34})$ cells form antigen 15 by infection with phage ε^{15}. These observations, together with Nakagawa's finding[5] mentioned above, indicate that the formation of antigen 15, at least partially, is a necessary prerequisite for the formation of antigen 34. Antigen 3 is also partially lost when 3, 15 cells are converted to (3), (15), 34 by lysogenization with ε^{34}; but it does not seem to be necessary for the formation of antigen

Table 1

Bacterial strain	Sensitivity to phage (/ml.)												O antigens
	ε^{15}			ε^{y}			C_{341}			ε^{34}vir			
	10^{10}	10^{7}	10^{4}	10^{10}	10^{7}	10^{4}	10^{10}	10^{7}	10^{4}	10^{10}	10^{7}	10^{4}	
$A(\varepsilon^{34})$	+	+	+	+	+	+	(+)	−	−	−	−	−	3, 10
A	+	+	+	+	+	+	+	+	+	−	−	−	3, 10
$A(\varepsilon^{15})$	−	−	−	−	−	−	−	−	−	+	+	+	3, 15
$A(\varepsilon^{15}, \varepsilon^{34})$	−	−	−	−	−	−	−	−	−	−	−	−	(3), (15), 34

Phage sensitivity was examined by spot test. ε^{y} is a mutant of ε^{15}. As to the phages C_{341} and ε^{34}vir, refer to Uetake *et al* (ref. 6). +, lysis −, no lysis; (+), abnormal lysis.

34, since antigen 3 of *S. anatum* is identical with that of group E_2 cells or of $A(\varepsilon^{15})$ cells but there is neither formation of antigen 34 nor loss of antigen 3 in $A(\varepsilon^{34})$.

Virus Release from Single Cells of Mouse Parotid Tumours

In vitro studies have shown that cells from polyoma-induced mouse tumours in mass culture can release virus, and that the release can vary in different tumours[1,2]. One of the factors responsible for this difference in release is the proportion of virus-releasing cells as measured by plating the tumour cells on mouse embryo monolayers, and determining the relationship between the number of tumour cells plated and the number of plaques[2]. The present communication is concerned with a study on single cells from mouse parotid tumours grown in microdrops, in order to obtain information on: (*a*) the proportion of cells releasing virus by plating in microdrops, and (*b*) the virus release per cell.

The parotid tumours were induced by inoculation of polyoma virus into 2- or 3-day old mice, and the tumour cells were dispersed by trypsinization with a 0·25 per cent trypsin solution (trypsin 1–300). Virus release per cell was tested either by seeding the cells directly in microdrops, or by seeding in microdrops cells that had been in mass culture. In all cases, the medium consisted of 0 5 per cent lactalbumin hydrolysate in Earle's saline and 20 per cent horse serum.

Cell suspensions were diluted in medium to about 10^3 cells in a 50-mm. Petri dish, and these were then used for the single cell seedings. The single cells were distributed freehand in microdrops with micropipettes under a dissecting microscope in an enclosed box, maintained at 37° C., with a humidified atmosphere containing 10 per cent carbon dioxide. The microdrops were made in 50-mm. Petri dishes under silicone fluid (Dow "Corning 200')[3], and the Petri dishes with microdrops were kept in an incubator with a humidified atmosphere containing 10 per cent carbon dioxide. The presence of only a single cell in each microdrop was checked by observation with an inverted phase-contrast microscope.

For collecting the samples, each drop was sucked up with a micropipette, and the cell was then washed twice with new medium. The complete sample per cell thus consisted of three drops, which were added to 0 2 ml. of medium. The samples did not include cell-associated virus. When cells were tested after they had been in mass culture (5 × 10^5 cells seeded in a 50-mm. Petri dish) the cultures were washed twice with medium and the cells removed from the glass by trypsinization with a 0·25 per cent trypsin solution for 10 min. at 37° C. Not all the cells came off the glass by this procedure, and only those that were detached after 10 min. trypsinization were used for the microdrops. The samples collected from th single cells were tested for plaque-forming units o mouse embryo monolayers as described previously The number of plaque-forming units was read at 1 days after inoculation of the monolayers, and in th case of *MP*12 again at 16 days.

The proportion of single cells, from 6 paroti tumours, releasing virus under these conditions shown in Table 1. Cells from two of these tumou were tested without previous mass culture, and th samples were taken at periods of 28–80 hr. afte seeding the single cells. The highest proportion o releasing cells, 9/19, was found in tumour *MP*2 and this tumour had also given the highest releas by cells in mass culture (hæmagglutination titre o 2,048 per ml. on the day equivalent to that used fo sampling from microdrops). In the other five tumours virus release was detected in only 3 out of 172 cell tested. None of the single tumour cells was seen t divide under these conditions.

Table 1. Proportion of Single Cells from Six Mouse Paroti Tumours releasing Virus in Microdrops

Tumour	Strain of mouse	No. of days in mass culture	No. of cells tested	No. of cells releasing virus	Release period (hr)
*MP*4	*AKR*	0	16	1	72
*MP*8	*AKR*	0	13	0	80
*MP*2	*AKR*	2	19	9	28
*MP*12	*DBA*/2	3	26	1	28
*MP*13	*SWR*	4	76	1	36 and 72
*MP*14	*SWR*	4	41	0	36 and 72

Total No. of cells tested, 191; total No. of cells releasing virus, 12

The number of plaque-forming units released pe cell in tumour *MP*2 during a 28-hr. release period is shown in Table 2. The release varied from 0 to 9 plaque-forming units per cell with an average of 5 for the virus-releasing cells. This figure is similar to that reported for the Rous chicken sarcoma[5], and whether parotid tumour cells have a regular release per day is now being tested. The release from the other 3 positive cells (Table 1) in 3 other tumours were 17 plaque-forming units in *MP*4, 4 in *MP*12, and 2 in *MP*13.

Table 2. Virus Release from Single Cells in Microdrops durin a 28-hr. Period

No. of plaque-forming units per cell	0	1	2	3	4	5	6	7	8	9
No. of cells	10	0	1	2	2	1	1	1	0	1

No. of cells releasing virus, 9/19, average release of virus releasing cells, 5 plaque-forming units.

The above results provide further information on the existence of a difference in virus release from different tumours, and they also show that under the conditions of these tests in microdrops, single cells from polyoma-induced parotid tumours have at most only a low virus release per day.

FORTHCOMING EVENTS

Wednesday, April 20

OYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, .7), at 5 p.m.—Annual General Meeting. Dr. J. M. Stagg: Presiaal Address.

ACULTY OF THE HISTORY OF MEDICINE AND PHARMACY (at the shipful Society of Apothecaries of London, Black Friars Lane, don, E.C.4), at 5.30 p.m.—Sir John Charles, K.C.B. "Roger m on the Errors of Physicians" (The Gideon Delaune Lecture).

Wednesday, April 20—Thursday, April 21

OIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (in the re Memorial Hall, Church House, Westminster, London, S.W.1), 0 a.m. daily—Symposium on "Advances in the Chemical Analysis oils, Fertilizers and Plants".

Thursday, April 21

STITUTION OF MINING AND METALLURGY (at the Geological ety, Burlington House, Piccadilly, London, W.1), at 5 p.m.— A. R. Gibson and Mr. J. R. Chalkley: "Production of Thorium al"; Prof. H. Borchert: "Genesis of Marine Sedimentary Iron s".

INNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, don, W.1), at 5 p.m. Mr R. I. Currie, Dr. D. H. Cushing and G. E. Fogg: "Productivity of the Sea".

ONDON MATHEMATICAL SOCIETY (at the Royal Astronomical ety, Burlington House, Piccadilly, London, W.1), at 5 p.m.— . E. Artin "On a Theorem of Gelfand with Applications to mber Theory".

HYSICAL SOCIETY, ACOUSTICS GROUP (in the Physics Department, erial College of Science and Technology, Imperial Institute Road, don, S.W.7), at 5.30 p.m.—Annual General Meeting, followed by R. S. Forster: "Noise—Legal Control".

OYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical gineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m. r. J. E. Allen: "On Reducing Costs of Space Research".

OCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP (at 14 Belgrave are, London, S.W.1), at 6 p.m.—Annual General Meeting, followed Mr. D. H. Collins: "Electrode Processes in Primary Batteries"

RITISH INSTITUTION OF RADIO ENGINEERS, LONDON SECTION (at London School of Hygiene and Tropical Medicine, Keppel Street, wer Street, London, W.C.1), at 6.30 p.m. Dr. J. G. Nicholls: erve Impulses from Stretch Receptors in Muscle".

OYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson use, 26 Portland Place, London, W.1), at 7.30 p.m.—Scientific pers.

Thursday, April 21—Friday, April 22

FERTILIZER SOCIETY AND SOCIETY FOR ANALYTICAL CHEMISTRY Church House, Westminster, London, S.W.1), at 2.45 p.m. on ursday and 9.15 a.m. on Friday—Symposium on "Fertiliser alysis".

LANT PHENOLICS GROUP (at Shoreditch College, Egham, Surrey) ymposium on "Current Chemical Research on Plant Phenolics".

Friday, April 22

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, ndon, W.1), at 4.15 p.m.—Discussion of papers. Chairman: Dr. Stoneley, F.R.S.

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 5.15 p.m.—Mr. George L. nssen and Mr. Richard W. James: "The Economics of Ship outing".

NSTITUTION OF ELECTRICAL ENGINEERS, EDUCATION DISCUSSION ROLE (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion "Broadening University Courses", opened by Prof. H. E. M. rlow.

ROYAL AERONAUTICAL SOCIETY, AGRICULTURAL AVIATION GROUP 4 Hamilton Place, London, W.1), at 7 p.m.—Meeting on "Pilot aining".

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, ndon, W.1), at 7.30 p.m.—Discussion Meeting on "Unconventional rms of Energy". Chairman: Prof. Pierre Auger. Speakers Prof. Sambursky, Mr. P. D. Dunn and Prof. M. W. Thring.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or fore the dates mentioned:

DEPUTY LIBRARIAN (with a good honours degree and administrative perience in a library) OF THE BROTHERTON LIBRARY—The Regisr, The University, Leeds (April 21).

ASSISTANT EXPERIMENTAL OFFICER (with a degree in science or rticulture) IN THE ENTOMOLOGY SECTION; and an ASSISTANT XPERIMENTAL OFFICER (with a degree or higher national certificate) THE CHEMISTRY SECTION—The Secretary, National Vegetable search Station, Wellesbourne, Warwick (April 28).

ASSISTANT, Grade B (with a good honours degree and preferably me teaching experience) IN CHEMISTRY at Brighton Technical llege, to teach general chemistry up to G.C.E. (Advanced Level) standard and to assist with the teaching of inorganic chemistry at degree level—The Director of Education, 54 Old Steine, Brighton (April 23)

EXPERIMENTAL OFFICER (with at least a pass degree or equivalent, and preferably considerable experience in a biochemical or pharmacological laboratory)—The Secretary, Institute of Animal Physiology, Babraham, Cambridge (April 23).

ASSISTANT LECTURER IN PURE MATHEMATICS—The Registrar, The University, Sheffield (April 25).

LECTURER (with a university degree in mechanical or chemical engineering or equivalent qualifications) IN CHEMICAL ENGINEERING —The Registrar, King's College (University of Durham), Newcastle upon Tyne 1 (April 25).

TECHNICAL ASSISTANT (with some knowledge of zoology), for culture work in protozoan research—Dr. E. M. Brown, Department of Zoology, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (April 25).

ASSISTANT ANALYST (member of the Royal Institute of Chemistry and practical experience in the examination of water samples)—The Public Analyst, City of Leicester Health Department, 7 Salisbury Road, Leicester (April 26).

SENIOR SCIENTIFIC OFFICER (with an honours degree in microbiology or in agricultural science, and postgraduate experience in food bacteriology, preferably in eggs and egg products) IN THE AGRICULTURAL BACTERIOLOGY DIVISION, Ministry of Agriculture—The Secretary, Civil Service Commission, Stormont, Belfast 4 (April 26).

SENIOR LECTURER or LECTURER IN PHILOSOPHY; and a SENIOR LECTURER or LECTURER IN AGRICULTURAL CHEMISTRY at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 27).

ASSISTANT (biochemist, with a first- or second-class honours degree) IN BACTERIOLOGY at the Western Infirmary—The Secretary of University Court, The University, Glasgow (April 30).

ASSISTANT IN THE DEPARTMENT OF CHEMISTRY—The Secretary, The University, Edinburgh (April 30).

ASSISTANT INSPECTOR (HORTICULTURE) (man or woman at least 25 on May 1, 1960, with a degree or diploma in horticulture and at least five years appropriate practical experience, and able to drive a car)—Department of Agriculture and Fisheries for Scotland, Room 266, St. Andrew's House, Edinburgh 1 (April 30).

ASSISTANT LECTURER IN CROP PRODUCTION; and an ASSISTANT LECTURER IN ANIMAL PRODUCTION, with special reference to Dairy Production—The Registrar, Wye College (University of London), near Ashford, Kent (April 30).

LECTURER (with a degree in engineering and Corporate Member of the appropriate professional institution) IN ELECTRICAL ENGINEERING at the Royal Technical College of East Africa, Nairobi—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (April 30).

LECTURER (with a veterinary, medical or science degree) IN VETERINARY PHYSIOLOGY—The Secretary of University Court, The University, Glasgow (April 30).

LECTURER or ASSISTANT LECTURER IN MATHEMATICAL STATISTICS, and a LECTURER or ASSISTANT LECTURER IN APPLIED MATHEMATICS —The Secretary, The University, Exeter (April 30).

LECTURERS (3) IN PHARMACEUTICAL CHEMISTRY at the Nigerian College of Arts, Science and Technology, Ibadan—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (April 30).

STATISTICIAN (Scientific Officer or Senior Scientific Officer), to be responsible for advising on statistical aspects of (*a*) the design and interpretation of environmental surveys of radioactive substances in human diet and agricultural materials; and (*b*) a programme of laboratory and field experiments in soil science and plant physiology —The Secretary, Agricultural Research Council, Radiobiological Laboratory, Letcombe Regis, near Wantage, Berks (April 30).

ASSISTANT (medical, veterinary or science graduate with B.Sc. (Hons.) in pharmacology or physiology) IN THE DEPARTMENT OF PHARMACOLOGY—The Secretary, Department of Pharmacology, University College, Merville Foster Avenue, Stillorgan, Dublin (May 1).

SENIOR LECTURER (registered medical graduate) IN ANATOMY— The Secretary of University Court, The University, Glasgow (May 1).

ASSISTANT LECTURER or LECTURER IN THE DEPARTMENT OF GEOLOGY (with special reference to Economic Geology and Geophysics) —The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (May 7)

LECTURER or ASSISTANT LECTURER (with a degree in physiology or some related subject) IN PHYSIOLOGY; and a LECTURER or ASSISTANT LECTURER (with a degree in biochemistry or some related subject) IN BIOCHEMISTRY—The Registrar (Room 29, O.R.B.), The University, Reading (May 7).

SENIOR LECTURER or LECTURER (honours graduate in electrical engineering or physics and with suitable research and teaching experience in electronics and radio communication) IN ELECTRICAL ENGINEERING—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (May 7).

ASSISTANT LECTURER (with a good honours degree in physics and preferably some interest in electronics) IN THE PHYSICS DEPARTMENT —The Dean, Guy's Hospital Medical School, London, S.E.1 (May 9).

ASSISTANT LECTURER (with special qualifications in pure mathematics) IN MATHEMATICS—The Registrar (Room 29, O.R.B.), The University, Reading (May 9).

RESEARCH FELLOW IN THE CHEMISTRY DEPARTMENT, for work on fundamental aspects of heterogeneous catalysis, in collaboration with Dr. G. C. Bond—The Professor of Chemistry, The University, Hull (May 9).

EDWARD A. DEEDS FELLOW (man or woman), for research in Engineering, Metallurgy, Chemistry, Physics, Mathematics or any cognate subject—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (May 10).

LECTURER/SENIOR LECTURER IN NUTRITION at the University of New England, Australia, to undertake teaching and research in Livestock Nutrition in the Department of Nutrition and Chemical Pathology—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, May 13).

Bowman Chair of Physiology—The Registrar, The University, Edgbaston, Birmingham 15 (May 14).

Chamber of Manufactures Chair of Physics in the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (May 15).

Lecturer or Assistant Lecturer in Botany at the University of Malaya (Singapore Division)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 15).

Lecturer (with special qualifications and experience in the food industry (other than the dairy industry) or in biochemical engineering) in Food Science—The Registrar (Room 22, O.R.B), The University, Reading (May 16).

Assistant Lecturer or Lecturer in the Department of Histology—The Registrar, The University, Liverpool, quoting Ref. CV/N (May 21).

Lecturer (graduate in engineering, with an interest in the application to agricultural operations of electronic and other control methods) in Farm Mechanization (Electrical Engineering)—The Registrar (Room 29, O.R.B.), The University, Reading (May 21).

Elder Chair of Physics in the University of Adelaide—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, May 31).

Reader or Senior Lecturer (with appropriate qualifications and experience needed to take charge of the newly established Statistics Unit) in Statistics at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, May 31).

Assistant Lecturer (with a Ph.D. in microbiology and research experience in this field) in the Department of Industrial Microbiology—Prof. E. Kuster, Department of Industrial Microbiology, University College, Ardmore House, Stillorgan Road, Dublin.

Astronomer (Senior Assistant) (with main interest in stellar astronomy)—The Director, Armagh Observatory, Armagh, Northern Ireland.

Demonstrator in Biochemistry—The Administrator, Department of Biochemistry, South Parks Road, Oxford.

Director (age 40–45, with a good degree or diploma in geology plus wide experience) of the Pakistan Geological Survey—The Recruitment Officer, Pakistan High Commission, 39 Lowndes Square, London, S.W.1.

Instructors or Assistant Professors (well-qualified candidates) in the Department of Chemistry—Prof. C. A. McDowell, Department of Chemistry, University of British Columbia, Vancouver 8, B.C., Canada.

Lecturers in the Mathematics Department—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

Research Assistant (chemistry graduate), to continue and extend a research project into the kinetics and mechanism of the reaction of sulphur monochloride with olefines—Head, National College of Rubber Technology, Northern Polytechnic, Holloway, London, N.7.

Research Fellow (Fellow of the Library Association)—The Secretary, Library Association, Chaucer House, Malet Place, London, W.C.1.

Senior Scientist (with experience in the use of radioactive isotopes for medical research), to organize an active research group and initiate a programme of fundamental research including the development of new clinical procedures—Dr. H. G. Thode, Vice-President, McMaster University, Hamilton, Ontario, Canada.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Coke and Chemistry, U.S.S.R., 1959, No. 8. (Organ of the State Scientific-Technical Committee of the Council of Ministers of the U.S.S.R.) (An English version of the monthly journal *Koks i Khimiya*, prepared by the Coal Tar Research Association, in collaboration with the British Coke Research Association.) Pp. 59. THE BALANCE OF FUNDAMENTAL AND APPLIED RESEARCH

THE ninth annual report of the (U.S.) National Science Foundation (see p. 362 of this issue) is the first to appear since the appointment of Lord Hailsham as Minister for Science; and although there is no institution in the United Kingdom which corresponds to the Foundation, it may be taken for granted that Lord Hailsham is likely to consider very carefully activities on which, in two years, the United States has increased its expenditure from some 40 million dollars to nearly 140 million dollars. Some of this work is parallel with that of the Department of Scientific and Industrial Research in Great Britain; but the latter's expenditure of £500,000 in research grants and approaching £1 million on studentships and fellowships looks small against the National Science Foundation's awards of some 46 million dollars in grants for fundamental research, with nearly 16 million dollars more for research facilities and 13 million dollars in graduate fellowships. Moreover, it is clear from the foreword of its chairman, Dr. Detlev Bronk, that the Foundation is tending to assume functions that the University Grants Committee discharges in Britain and that, like that Committee, it is succeeding notably in strengthening the universities in their true functions of research and teaching without encroaching on their freedom.

Nor is this the only contribution to education which the National Science Foundation is making. It was already concerned with the quality and the extent of science teaching in the schools and in the universities of the United States before the National Defense Education Act of 1958 widened its responsibilities in this field, and in three years its expenditure for such purposes has more than trebled. On a much greater scale than the Department of Scientific and Industrial Research in Britain, it is concerned with the dissemination of scientific information, and the current report attests not so much the magnitude of the resources which are made available for such purposes in the United States as the vision and vigour with which these purposes are pursued by the National Science Foundation.

Probably to the British reader, however, the most suggestive part of the report is that which, following the stimulating statement of the director, Dr. A. T. Waterman, surveys the re-appraisal and re-organization of the status of science in the United States during 1958–59. In that section, as in Dr. Waterman's statement, the essential factors which determine the resources available for research and development and condition their deployment are shown, and it is possible to distinguish how far the institutions devised for one particular set of national circumstances react on those performing other functions. The National Science Foundation is an institution peculiar to the United States, and the fact that it performs certain functions, such as the award of fellowships or research grants or the administration of science fellowships for the North Atlantic Treaty Organization which in Britain are executed by the Department of Scientific and Industrial Research or the University Grants Committee, does not imply that either of these bodies should necessarily be modified on the model of the National Science Foundation. It does, however, suggest that the comparative scale or scope of operations might be studied.

Dr. Bronk stresses particularly the way in which, during the past ten years, the support of science has become generally recognized in the United States as a proper and necessary function of the Federal Government. This is attested by the increase, in that period, of the budget of the National Science Foundation from 3·5 to 155 million dollars, while at the same time the universities have been receiving more assistance than ever from individuals, private foundations and industry. If Dr. Bronk's assumption that the Foundation has stimulated this increased and more widespread support of science is sound, it may be worth while for the Minister for Science in Great Britain to consider rather closely exactly how the Foundation functions, more particularly since it is incontestable that the Foundation has notably succeeded in strengthening American universities without in any way encroaching on their prerogatives or deflecting their policies.

Dr. A. T. Waterman's statement, however, is designed to discourage any facile optimism. Science, he observes, is increasingly an instrument of both national and international policy, and for all that has been done, there is still in the United States an alarming dearth of trained teachers, especially for secondary schools, and no prospect that the requisite number will be forthcoming. Indeed, he suggests that the United States has not yet come to grips with the major problem; and his further comment that the cultivation and staffing of a professional group can be realized adequately only if the career is a rewarding one from the point of view of salary, prospects and prestige, as well as the deeper satisfactions that go with the opportunity to serve, is one that bears vitally on the recommendations of the Crowther Report. It is above all the supply of trained teachers that determines the practicability of raising the school-leaving age, and when full weight is given to the argument of the Crowther Committee in regard to timing, the urgency and priority lie on increasing the number of teachers.

Dr. Waterman makes a further comment on the man-power situation. In spite of the surveys made by the Advisory Council on Scientific Policy's Standing Committee on Scientific Man-power, the studies of the National Science Foundation provide the United States with considerably fuller information about the situation in the United States than is available about the position in Great Britain. About a quarter of American scientists and engineers are engaged in research and development, and Dr. Waterman points out that this pool of talent is the limiting factor in the national research and development effort, and its competence determines the effectiveness of the nation's undertakings. Its size and quality, moreover, are only increased or improved as a result of long-term operations, and there are definite limits to the extent to which the special skills and the fields that will be important in the future can be forecast.

This last is a factor to be weighed when considering whether or not to embark on new fields such as that of space research, and Dr. Waterman is emphatic as to the need for carefully selecting the fields of research, particularly in applied science, in which even a nation with such immense resources as those of the United States can wisely engage. He regards the establishment of priorities, particularly in fields involving highly expensive equipment or installations, as fundamentally a matter for Government; and it was for this purpose that the Federal Council on Science and Technology was recently established. The functions of that body correspond broadly with those of the Advisory Council on Scientific Policy in Britain, and it should be a first objective of the Minister for Science to see that the Advisory Council is effectively placed to co-ordinate the interests and responsibilities of the various Government bodies with research and development programmes, to identify research needs and to advise him on the more effective utilization of our scientific and technological resources and the planning and administration of the programmes needed.

What stands out particularly from the report of the National Science Foundation is the way in which the educational and research aspects are interlocked and co-ordinated policies are now being concerted. Dr. Waterman, for example, advocates a man-power policy which endeavours to identify talented students in order to ensure that those with aptitude for science and engineering receive the appropriate professional training, more especially in fundamental science. The close relation between teaching and research leads him to emphasize the economic limits on research, and the way in which fundamental research, on which the United States is spending only some 8 per cent of its total expenditure of 10,000 million dollars on research and development, is the main limiting factor on development. Dr. Waterman makes the further observation, which also Lord Hailsham should note, that failure to provide full support may seriously impair the effectiveness of a project.

Dr. Waterman's main argument is for more generous support of fundamental research in the United States and for a more careful scrutiny of the effort devoted to applied research. The question of priorities is equally important in Britain, though it may well be that it is the effort in applied research that should be increased. Be that as it may, it is as essential as in the United States that the programme that is evolved should be supported by an informed body of public opinion, and that the resources placed at its disposal should be adequate in the first instance and not liable to be curtailed from year to year.

This will become the more important if there is any considerable extension of the system of research institutes, to which Sir Harry Melville referred in an address on scientific research in British universities given at Newcastle upon Tyne on September 22. At present the system is limited to nuclear physics, where the Department of Scientific and Industrial Research has been financing in some six universities the construction and largely the maintenance of particle accelerators which are now housed, maintained and operated in a central institute or institutes for the benefit of more than one university, so as to facilitate economic operation, as has been done at the European Organization for Nuclear Research in Geneva. Similarly, the National Institute for Research in Nuclear Science, where a proton synchrotron of an energy of 7 GeV. is under construction, has not a wholly permanent staff, and its work derives inspiration from the university staff who work there.

Much has still to be done to work out the most satisfactory arrangements for such institutes, but Sir Harry Melville stated that about 27 per cent of university expenditure on research in the United States is used in this way, and that experience has established definite benefit to the universities from such an association. The mounting costs of research equipment may well encourage similar developments in other fields, and it is as desirable that the implications, administrative as well as financial, of such a system of special institutes in association with the universities should be fully examined before some urgent problem leads to the establishment of procedures that are unsound. The report "Strengthening American Science", issued in December 1958 by the President's Science Advisory Committee (see *Nature*, 183, 1215; 1959) showed that this and other problems of financing university research and the relations between Government and universities are receiving close attention in the United States by minds as sensitive to the essential issues as are the University Grants Committee and the Advisory Council on Scientific Policy in Britain.

On the balance of scientific research, the National Science Foundation indicates some important developments. The Foundation has now assumed responsibility for research on the modification of weather, and in March 1959 announced grants for this purpose totalling 1·13 million dollars. At the same time it announced the establishment of an Antarctic Research Programme to continue scientific activity based largely on certain programmes of the International Geophysical Year. There have also been calls from the scientific community for increased effort in particular critical fields. For example, a group on medical research has urged systematic increase in Federal support for medical research from 330 million dollars in 1957 to about 900 million dollars in 1970, with at least a doubling of the number of research workers. A Committee on Oceanography has recommended doubling the support of fundamental research in the marine sciences during the next ten years at a cost of a further 650 million dollars, about half of this coming through the National Science Foundation. A report on atmospheric research envisaged an institute established and operated by a university committee and financed through the National Science Foundation at a capital and operating cost over six years of some 70 million dollars, as well as further encouragement and support of research in atmospheric physics in existing university departments. President Eisenhower, moreover, has already recommended the financing by the Federal Government of the construction of a large new electron linear accelerator over six years at a cost of some 100 million dollars. The statement also recommended further support of research in high-energy physics by the Atomic Energy Commission, the National Science Foundation and the Department of Defense, and that support for the construction and operation of high-energy accelerators should be increased to 135 million dollars by 1963.

It is not only the scale of effort in the United States that is changing. The Federal organization to meet the scientific needs of the nation is more fluid, and proposals have been made for the creation of departments of science and technology or of science, and for a commission to examine such proposals. It appears, however, that such measures as the establishment of the Federal Council for Science and Technology and the appointment of Dr. W. R. Brode as science advisor to the Secretary of State, following the earlier appointment of a Special Assistant for Science and Technology to the President himself, have largely provided what is needed to support the National Science Foundation, and these arrangements should be given full opportunity to function before decisions are taken as to the need for, or value of, some further centralized agency. Dr. Brode has already expressed deep concern with these questions of organization, but while he is obviously not entirely satisfied that the recent changes provide all that the United States needs, he seems disposed to advocate further study of the organization of science and scientific policy rather than immediate action.

The two points in the work of the National Science Foundation that appear to deserve most careful attention in Britain are the work being done to extend and improve the quality of education in science and technology, and the means by which the balance of research is fostered or varied. On the first, it is not the scale of educational effort that should be noted: Sir Harry Melville has forecast expenditure by the Department of Scientific and Industrial Research on studentships and fellowships of £4 million or more in a few years, probably on some 3,000 awards, or 30–40 per cent of the present total number of research students in the universities, with a further £1–2 million on research grants. It is rather the other measures adopted by the Foundation to assist teachers of science and technology to improve their standard of teaching, to assist the schools to improve their equipment and particularly to make the studies of new techniques and methods of presentation, which could make even the existing supply of teachers more effective.

Here very little has yet been done. The National Science Foundation obviously has a considerable advantage in being able to undertake such studies side by side with its efforts to assist students to take up courses in science and technology and to undertake research; but the Minister for Science is well able to deal with the situation on appropriate lines in Britain. He has the authority to secure whatever co-ordination may be desirable between the work of the Agricultural Research Council, the Medical Research Council, the Overseas Research Council and the Department of Scientific and Industrial Research in such matters as the award of research grants, fellowships or studentships. Further, he would seem to be the most appropriate person to explore the possibility of increasing co-operation with industry and elsewhere.

Very great stress was laid on this by Sir Harry Melville from two points of view. First, Sir Harry emphasized the importance of increasing support for the universities of Britain from other sources so as to prevent their dependence on financial support from the State becoming overwhelming. At the same time, he is convinced that in carrying the main responsibility for fundamental research, the universities should also be responsible for seeing to its balance and the closing of any gaps that may occur. Secondly, he urged that multiple sources of support provided an insurance against mistaken decisions and the refusal of support to a worthy project. The soundness of that view is to be seen to some extent in the existence of differing opinions as to the importance and value of space research, and it might become more important as efforts are made to extend the amount of applied research undertaken in Britain.

Mr. Aubrey Jones, former Minister of Supply, has frankly advocated the establishment of a Minister for Technology rather than a Minister for Science, and rests his argument largely on the prospective reduction of defence expenditure relative to national income. He does not believe that, with defence expenditure little more than 7 per cent of the national income and the defence scientific effort approaching 50 per cent of the total scientific effort of Britain, the rate of technological advance is likely to be maintained. While he thinks that the economic burden of armaments is exaggerated, he suggests that a prime responsibility of the Minister for Science is to find a substitute for the technological role taken by armaments in a free society.

If this contention is sound, clearly the Defence Research Policy Committee and the Advisory Committee on Scientific Policy may require to work much more closely together. Here again it would seem that the Minister for Science is best placed to supply the necessary guidance and to deal with those factors, such as excessive secrecy and departmentation, which may hinder the free exchange of views and information. The problem of communication indeed requires to be attacked with far more energy, vision and urgency than is apparent in recent references to it in reports from the Advisory Council. There is indeed much to be done to prepare the way for the difficult decisions that cannot long be postponed regarding the balance of research effort, both fundamental and applied, in Britain; and the deployment of our trained man-power in defence, industry, teaching and elsewhere, and the measures to be taken to ensure that the supply is adequate in quality and in numbers. The National Science Foundation's report, although prepared mainly for American readers, indicates numerous points calling for fresh thought and even inquiry in Britain, and it is to be hoped that it will be carefully studied by the Minister for Science and his advisors, the Parliamentary and Scientific Committee and professional associations of scientists and technologists, who are able to assist in forming that intelligent public opinion required to sustain public policy.

APPLIED RADIATION CHEMISTRY

Chemische Reaktionen ionisierender Strahlen (Radiation Chemistry)

Herausgegeben von Prof. Hermann Mohler. Pp. 299. (Aarau und Frankfurt am Main: Verlag H. R. Sauerlander und Co., 1958.) 30.80 D.M.

A SIGNIFICANT diminution in the cost of atomic power could be achieved if the energy at present 'lost' as radiation were used to achieve large-scale chemical production or processing. In many countries, private and government laboratories exist to explore the possibilities of applied radiation chemistry, and already a number of processes have been, or are being, used commercially. Hitherto the use of radiation in the chemical industry has been very small, primarily because radiation merely generates in chemical systems reactive species such as ions and/or free radicals which in most cases can be produced in a more controlled manner by more conventional chemical means. This fact and certain inherent disadvantages in the use of radiation are likely to limit its successful application to fields where chemical methods are either non-existent or very difficult to apply. The book under review has been written in the belief that the time has now come when the chemical technologist should know something of the principles and applications of radiation chemistry.

The book originated in a course of lectures in the University of Basle in 1956, and some of the authors contributing to this book took part as lecturers. After a brief definition of the subject, the first half of the book is concerned with a discussion of the necessary background knowledge of radioactivity, followed by an account of radiation sources (parts of which read like a technical sales brochure) and dosimetry, with a minor chemical digression (pages 54–68) in which a sketchy account of some radiation chemical mechanisms is given. The latter part of the book deals with the interaction of radiation and matter and presents somewhat cursory accounts of selected radiation-induced reactions in solid, liquid and gaseous phases, and concludes with two chapters, rather surprisingly in English, entitled "The Effects of Atomic Radiation on Polymers" and "Radiation-induced Reactions of Potential Industrial Importance".

The book displays several of the disadvantages of composite authorship. For example, in the whole of the last chapter the phrase 'radiochemical reaction' is given a meaning quite different from that commonly accepted and from that carefully specified by the editor and writer of the introduction. Again, there is a great unevenness in level of treatment; the chapter on polymers, though by an expert, is almost at the level of popular science exposition, whereas that on dosimetry is a good deal more profound. These defects are minor in comparison with several distorted and often erroneous notions about radiation chemistry which the book contains. The stated origin of the hydroxyl radicals in irradiated water (p. 63), the mechanism of formation of H_3O^+ on electron impact on water vapour (Table 4·08, p. 194), and the mechanism of the reduction of ceric ions (p. 152), all contain inexcusable errors which are not printing slips. The complete omission of ion-molecule reactions and the inadequate treatment of the competition between diffusion and combination of radicals, both matters of central importance, are serious deficiencies. When one reads phrases such as the following about the oxidation of sulphur dioxide by oxygen in aqueous solution, "Attention will have to be given to the effect of trace metals, for example, iron and copper, on the reaction" (p. 251), or "There is no published information to indicate to what extent chain reactions play a part" (p. 249), one marvels how the author of this chapter can have overlooked the classical works of Bäckström and others. Any chemist or chemical technologist using the Fricke dosimeter to determine doses or dose-rate who uses the *G* values for this system given on pages 156 and 161 must be content with values which will be 6–7 per cent too high.

Apart from the dropping of an 'h' from Shrivenham, the book is well printed and produced.

F. S. DAINTON

THE THEORY OF DAMS

The Theory of Storage

By Prof. P. A. P. Moran. (Methuen's Monographs on Applied Probability and Statistics.) Pp. 111. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1959.) 13*s*. 6*d*. net.

MANY of the individual problems of applied probability have a very respectable antiquity; thus queueing theory began with Erlang in 1908, what we now call birth-and-death processes were first studied by Galton and Watson in 1873, and the use of probabilistic models in physics and astronomy can be traced back to much earlier dates than these. But it was not (in Great Britain at least) until just after the Second World War that the full range of possibilities was widely recognized; during the past fifteen years the subject of applied probability has grown to such an extent that it now rivals in importance its elder sister, the statistics of experimentation. That the publishers of this new series of monographs recognize this fact is clearly shown by the general title which they have given to the series, by the individual titles of the five volumes so far announced (only one of these is concerned with statistics as ordinarily understood), and by their happy choice of Prof. M. S. Bartlett as general editor of the series.

In the monograph reviewed here Prof. P. A. P. Moran of the Australian National University, Canberra, writes on the theory of storage systems in which either the input or the output is of stochastic character. Most space is given to problems of the first type ("The Theory of Dams"); here a random input of water feeds a reservoir or a system of reservoirs subject to overflow and release rules of various types, and one is interested both in the conditions for statistical equilibrium and the statistical distributions which characterize it, and also in transient phenomena such as the risk that the reservoir will run dry within a given time period when the initial conditions are known. This is a very recent branch of applied probability, and can be said to be Prof. Moran's peculiar creation, for apart from some exceedingly interesting pioneer work by Hurst practically all the mathematical papers devoted to the subject have been written by Moran himself or by those influenced by him. The programme of research opened up by Moran in 1954 is still very far from complete; much more remains to be done on systems with a (random) continuous input, very little is known yet about the behaviour of networks of reservoirs, and a satisfactory treatment of correlated inputs is still lacking (as it is also in queueing theory, although recent work by Dagnall, Winsten, and Wishart has shown that significant progress can be made if the problem is suitably formulated). Those familiar with the earlier literature will be very grateful to the author for this timely survey of what has been done and of what remains to be done; others will be equally grateful for the possibility which this book offers them of joining in a very active programme of research.

D. G. Kendall

QUANTUM EFFECTS ON A MACROSCOPIC SCALE

Liquid Helium

By Prof. K. R. Atkins. (Cambridge Monographs on Physics.) Pp. x+312. (Cambridge: At the University Press, 1959.) 60*s*. net.

The strange behaviour of liquid helium at low temperatures has been the subject of much work and thinking for some time. Ever since Kamerlingh Onnes succeeded in liquefying helium some fifty years ago, work has been going on with this single substance; more and more new phenomena have been discovered and a new field of experiments and theory has been established. At first, the difficult techniques for obtaining the necessary low temperatures meant that the work was concentrated in a few laboratories which became famous in this field. With the more recent methods these low temperatures are easier to obtain, and much work is going on in many places all over the world. The subject is still in rapid development. A new monograph which tries to select the essential features in such a vast field of experiments and theoretical thinking is very welcome. At the same time, it is a somewhat bold enterprise to write a monograph on such a rapidly progressing subject. A few points were already out of date by the time that the book was printed.

The wide variety of strange phenomena connected with liquid helium led slowly towards a pattern of basic facts. Some of these are by now essentially understood, others are not, and many more are perhaps still to be discovered. Theoretical ideas and experimental discoveries proceeded hand in hand in a fruitful co-operation. There are many striking examples of this interaction between theory and experiment. The concept of elementary excitations which move around in the superfluid background was introduced by Landau and is essential for the understanding of many properties of liquid helium. These excitations, phonons and rotons, characterize the low-lying excited states of the system. Landau's predictions about the excitation spectrum have been recently confirmed by neutron-scattering experiments. The elementary excitations form the 'normal component' of the liquid, which together with the superfluid component leads to a 'two-fluid' theory from which many features of the hydrodynamic and thermal behaviour of liquid helium can be understood. Other features which are less well understood are related to the formation of vortices. According to the ideas of Onsager and Feynman, the strength of these vortices has quantized values, a prediction which has found experimental verification in the past few years.

Quantum properties play an important part in the whole behaviour of liquid helium, and some manifestations of these are on a macroscopic scale. The Bose statistics obeyed by the helium-4 atoms seems also to be essential for the superfluid behaviour of helium. The helium-3 isotope which obeys Fermi statistics does not show superfluidity. Though many features of liquid helium are understood, much progress is still needed in a detailed theoretical description. The phenomena are related to the collective behaviour of a large number of particles, and the wave mechanics of such a system is of considerable mathematical complexity. But a better understanding of the collective behaviour of helium atoms may be of significance also in connexion with other similar problems of physics.

The book under review succeeds in a fair selection of the relevant experimental facts in making a good systematic treatment. This will be of value both to the expert and for reference. Some parts in the theoretical sections are perhaps not of the same standard, and especially the author's estimate of the theoretical achievements seems to be slightly over-optimistic. The book covers a lot of ground, it makes pleasant reading, and will be enjoyed not only by the specialists but also by those who look merely for orientation in this rather exciting subject.

J. G. Valatin

FRESHWATER INVERTEBRATES

A Guide to Freshwater Invertebrate Animals

By Dr. T. T. Macan. Pp. x+118. (London: Longmans, Green and Co., Ltd., 1959.) 11*s*. 6*d*. net.

The importance of freshwater biology for scientific, economic and educational purposes has greatly increased in recent years and the many biologists, both amateur and professional, now interested in the subject, will be grateful to T. T. Macan for writing an attractive, straightforward and well-illustrated "Guide to Freshwater Invertebrate Animals".

The line drawings, of which there are more than two hundred, are simple, clear and attractively finished and make up for some of the carelessness in the choice of words. To anyone unfamiliar with the conventions applied in describing mollusc shells the definition of a sinistral shell will mean very little: "if it be held upright with the aperture towards the observer the aperture is to the observer's left". Readers requiring a definition of sinistral in this context are the very ones least likely to know the meaning of 'upright'. Fortunately most of the ambiguities and other obscurities can be resolved by reference to a figure or to an opposing couplet in the key; but this takes a little time, and the distractions they evoke are further aggravated by expressions like "Swimming quick" which may be a grammatically appropriate antithesis to "Swimming laboured", but could easily have been avoided.

Apart from these minor blemishes the "Guide" is a pleasure to use. The practice of giving the dimensions of the specimens figured in millimetres rather than giving the magnifications is commendable and will save much mental arithmetic. It is, however, unfair to expect all the readers for whom the book is intended to know that the length of an insect, for example, does not include in its measurement any appendages projecting at either end.

Most authors of taxonomic keys become slaves to the system, and for the sake of uniformity attempt to find simple characters to separate large groups which are too complex for this to be done satisfactorily. It is for this reason that most keys require the reader to inquire into the most obscure and insignificant details, particularly in the early stages of the key, where the groups to be separated are the most complex. This is very discouraging until the student learns by experience how to bypass the difficulty by recognizing the major groups by sight rather than by resolving the alternatives presented in the key. Dr. Macan avoids this trouble in a delightfully simple way: where to persist in the format of a key would lead to the use of impracticable alternative questions he abandons the format and substitutes a straightforward explanatory paragraph. By way of compensation, perhaps, the author makes use of the key format for his references to further literature. The number of species of freshwater invertebrates in Great Britain is far too great for them all to be dealt with in a single work, so in many places the key inevitably ends in a family or other group name rather than a genus or species, and here where the investigator wants it is a reference to further literature on the group. Macan's "Guide" is thus more than a key to the invertebrates, it is also a master key to other keys.

J. P. HARDING

DOWSING—FACT OR FICTION?

Water-Witching U.S.A.

By Evon Z. Vogt and Ray Hyman. Pp. xi+248. (Chicago: University of Chicago Press; London: Cambridge University Press, 1959.) 37*s.* 6*d.* net.

THE difficulties of popularizing science are well known; they are probably greatest in fields such as psychology and sociology, where most readers are quite unaccustomed to the possibility of a scientific approach. The book under review shows what can be done even in a field that superficially might seem rather unlikely. In turning to dowsing or 'water witching', the writers, of course, have the advantage that most lay readers will have some interest in the problem and will at least have heard of the claims made for this 'science'. Their account is well written, well documented, critical in the best sense and, above all, intensely readable. It can be recommended to anyone interested in the subject as a model of popularization, and few people will lay down the volume without having learned a few new facts at least from the authors' wide-ranging discussion.

In their book they pass from the reasons for dowsing, through its history, to a consideration of the question of whether it does in fact work or not. As they point out, there is fairly universal agreement that the stricter the controls become which are imposed on the dowser, the less frequently does his score deviate from the chance-level. In this, there is a striking parallel to other sets of beliefs, such as those associated with mediums, clairvoyants, phrenologists, graphologists, and Freudian psychotherapists. The unbiased reader will be unlikely to disagree with their conclusion that there is no scientific basis for water divining, and that recourse to it and belief in it are both based on psychological causes which are independent of reason and scientific proof. Particularly good in this connexion is their discussion of scientific methodology applied to problems of this type; even those least aware of modern psychological methodology could scarcely fail to follow their description step by step of the reasons why controlled experiments are necessary, and the way in which such experiments should be carried out.

The authors go on to discuss psychological theories which might account for the muscle twitches of the dowser, including a discussion of the famous 'talking horses' and other so-called 'parapsychological' phenomena. Here again, the discussion is lucid, well supported by strictly experimental findings, and altogether convincing. Their main point in bringing in these apparently extraneous facts is this. Modern psychology has demonstrated the truth underlying Carpenter's ideo-motor theory, to wit, that a person's thoughts tend to be mirrored in certain small incipient muscle movements or twitches. These can be used as signs or signals by a clever medium. By the same token, they can also, when amplified by the forked twig held by the water diviner, lead to an unconscious indication of the diviner's thoughts about the likelihood of water-bearing properties of a particular piece of ground—notions themselves in many cases derived from his personal familiarity with the neighbourhood, or even semi-scientific knowledge of geological indications.

The book ends with some chapters on the kind of people who undertake dowsing, the kind of people who employ dowsers, and the reasons why they do so. The facts discussed there are derived from the United States only, where dowsing appears to be much more prevalent than in Britain. The interested reader might like to consider whether the descriptions furnished by Vogt and Hyman of the typical dowser and his employer fit in with national stereotypes about the United States and Britain; it would certainly be interesting to have some similar facts about dowsing in the latter. Even without this, however, most readers will find this an interesting, enjoyable and well-written book, which will tell them all they need to know about 'water witching'.

H. J. EYSENCK

British Industrialists

Steel and Hosiery, 1850–1950. By Charlotte Erickson. (The National Institute of Economic and Social Research. Economic and Social Studies, Vol. 18.) Pp. xxi+276. (Cambridge: At the University Press, 1959.) 40*s*. net.

THIS book gives the results of a survey of the social origins and careers of about 1,000 managing partners and executive directors in the hosiery industry of the Nottingham area and in the heavy-steel industry during the past one hundred years. It is thus in the first place a historical study, but the work was planned on the assumption that important differences might exist in the recruitment of management by different industries, depending upon their age, traditions, structure and organization. It does not claim more than to present some empirical data on the social origins of business leaders and on the use made of the natural ability of able individuals, and makes no attempt to construct principles for the selection of leaders.

Nevertheless, as Prof. T. S. Ashton points out in his foreword, this admirably produced volume contains material highly relevant to present issues. It gives some background for present-day thinking about the selection of leaders and about training for management that should be carefully weighed in planning the expansion of higher technological education at the least. These studies bear closely on such questions as what constitutes the best education and experience for business leadership, the relative place of education and of experience, the appropriate age of appointment of directors, as well as retirement. Such questions cannot be dealt with in averages without regard to the particular individual's rate of development and retention of powers, but they need consideration, and this book demonstrates the practicability of obtaining evidence and shows how it can be obtained. Moreover, the two industries actually chosen offer the possibility of some tentative inferences about the growth of the impersonal corporation upon the selection of business leaders in Great Britain. Indeed the book may well gain in value as further studies on such lines are made in other industries and the results become available for comparison.

R. BRIGHTMAN

The Study of Man

The Lindsay Memorial Lectures, 1958. By Prof. Michael Polanyi. Pp. 102. (London: Routledge and Kegan Paul, Ltd., 1959.) 7*s*. 6*d*. net.

THESE lectures form a most valuable companion to the author's "Personal Knowledge", in which he goes far towards rejecting the objectivity of science in that, as a discipline, it is commonly thought of as detached and impersonal. An individual, even passionate, element is essential. The three discourses are entitled (1) "Understanding Ourselves", (2) "The Calling of Man", (3) "Understanding History". This emphasis upon understanding rather than upon prediction (the usual goal in theoretical studies) marks the writer as a true epistemologist. The importance of such an outlook to-day lies in its capacity to offset at least some of the evils of specialization without becoming merely dilettante in the process.

The author is now ready to do something well worth the attempt, namely, to transpose much of Gestalt-psychology into a theory of knowledge. Why this has not happened before is largely because its devotees were too passive, and inclined to under-estimate the personal element. In this, and in many other ways, Prof. Polanyi shows himself an artist, not least when he insists that those to whom the internal splendours of mathematics are a closed book have no knowledge of the subject.

It remains to see all this in the light of the late Lord Lindsay's outlook on education, and his early efforts on behalf of the University College of North Staffordshire in particular. He would have delighted in the liberalism which makes the act of knowing an urge to service.

F. I. G. RAWLINS

Russian–English Glossary of Solid State Physics

Edited by I. Emin. Pp. iii+90. (New York: Consultants Bureau, Inc., 1958.) 10 dollars.

Russian–English Glossary of Optics and Spectroscopy

Pp. iv+78. (New York: Interlanguage Dictionaries Publishing Corporation, 1959.) 10 dollars.

THESE two glossaries are of about the same size, the same format and edited by the same editor, but are published by different organizations. They represent very useful compilations of Russian terms belonging to the respective branches of physics, but although each glossary contains some 4,000 terms the user of these glossaries, as of any other specialized technical compilation, will often find certain terms missing. This applies to all specialized glossaries for the obvious reason that there are no hard and fast separations between specialized and general terms in science. Thus, for example, a very important Russian term of a French derivation 'etalon', meaning 'standard', such as 'standard sample' or 'standard measure', also the term 'brus' or 'brusok' meaning 'bar', or again names of certain chemical compounds or common minerals, are all missing from these compilations. The price of each of these glossaries is rather high.

S. I. TOMKEIEFF

Outline of Human Genetics

By Prof. L. S. Penrose. (Contemporary Science Series.) Pp. xii+146. (London: William Heinemann, Ltd., 1959.) 12*s*. 6*d*. net.

THIS is an excellent and lucidly written introduction to human genetics for the general reader. As one would expect, the treatment is well balanced and the factual basis correct and up to date. Of particular interest is the last chapter ("Eugenics and Dysgenics"), in which the author, himself the Galton professor of eugenics in the University of London, gives many good reasons for a conservative attitude towards practical measures in this field.

H. GRÜNEBERG

Die Cactaceae

Handbuch der Kakteenkunde. Von Curt Backeberg. Band 3: Cereoideae (Austrocactinae). Pp. iii+1361–1926+tafel 108–160. (Jena: Gustav Fischer Verlag, 1959.) 85 D.M.

THIS further volume of Herr Backeberg's colossal new handbook to the Cactaceae (*Nature*, 184, 1010; 1959) continues the account of the subfamily Cereoideae as far as the end of the 'sippe' Austroechinocacti of the subtribe Austrocactinae. Among the larger genera included are *Lobivia* (72 species), *Gymnocalycium* (58) and *Parodia* (36). As before, the volume is copiously illustrated.

A BASIS FOR A GENERAL SYSTEM OF INSECT MIGRATION AND DISPERSAL BY FLIGHT

By C. G. JOHNSON
Rothamsted Experimental Station, Harpenden

WHENEVER the start of a 'mass migration' of insects has been described—and this is very rare in spite of a voluminous literature—the insects have nearly always been making either their first flight as new adults or one very soon afterwards. This fact is usually mentioned only incidentally and has been observed intentionally in very few insects[1–15]: it has never been brought forward as a general principle, though it may provide a central feature for a long-needed, general system of insect migration and dispersal.

Studies of insect migration have usually been preoccupied with special qualities of the flight such as persistence, long distances travelled, collective flight or apparent control over the direction of displacement; and migration is usually defined in these terms[1–15]. But no matter how spectacular these behavioural qualities may be, they are so variable that definitions based on them as to what is or is not 'migration' or what is 'active' migration and what is 'passive' dispersal, become arbitrary, controversial and unsatisfactory when applied to all the types of insect which are said to migrate.

I suggest that the only common feature which is obvious at present in the mass migrations of insects in general is the active exodus flight by new adults from the breeding site followed by one or more flights, varying in character from species to species, to a new breeding site. This is what I shall mean by migration. I shall take mass migrations as the starting point for analysis.

Records of Post-teneral Migration Flights

I have so far found no exceptions to my conclusion that mass migrations begin in the first place either as first flights at the end of the teneral period or soon afterwards.

The examples supporting the conclusion are given in Table 1 and refer to recognized migrants like *Vanessa cardui*, *Ascia monuste*, locusts and dragonflies and to less spectacular ones; to organized drifters like aphids, and to Isoptera and crepuscular or nocturnal chironomids, which normally fly a very short distance but which can also be said to migrate in the above sense of the word. These examples include insects of several orders and cover a wide range of flight speed, duration and orientation.

The teneral period is taken here as beginning at emergence from the last immature instar and ending at full flight-worthiness, although pigmentation may be incomplete as in dragonflies. It varies inherently from about 1 hr. (*Vanessa cardui*)[16,17] to several days (locusts)[4,18,19]; its length is affected by temperature, as with any developmental process[20].

Perspectives in Migration Studies in the Light of the Post-teneral Flight

A recognition of the principle of post-teneral exodus flight brings new order and interesting speculation to the subject.

(1) *Periodicity of the first flight.* The daily synchronization of mass flights is not primarily behavioural, as with birds. Except in ants and termites it is caused by rhythms of emergence from the last immature instar, and by variation in the teneral period with changing temperature, in association with light and temperature thresholds for take-off[8–13]. Flight peaks may be repeated daily or within the day: total numbers migrating each day follow the curve for seasonal alate population change[47]. Seasonal synchronization may be caused by breaking of diapause[48]. Such periodicities are fundamental to the mass migration process.

This synchronized flight by individuals without apparent effect on each other is often called 'swarming'. This term is also used to describe aggregations by mutual attraction, which is quite a different process.

(2) *Possibility of teneral or post-teneral 'conditioning'.* The initial orientation of the insect in flight is probably 'imprinted' during the teneral period, or determined at take-off. The analogy with flight of bees comes to mind. Distances flown (within 24 hr.)

possibly depend on the time of day when flight maturity and take-off occur, that is, on the period remaining before flight is stopped by darkness or falling temperature. Too long an enforced wait before take-off, leading to sexual maturation or fertilization, apparently inhibits migration altogether in *A. monuste*[13] and *Hemileuca oliviae*[37]. Reversal of positive phototaxis with changes in temperature (and humidity)[49–51] may influence take-off behaviour and subsequent flight.

Thus, variation in initial orientation and flight duration, or whether the exodus flight will occur or not, could be expressed collectively according to the daily periodicity.

(3) *Take-off flight*. The individual take-off flight at the exodus appears to be very similar for several insects of different orders. It is often described as a vigorous flight upwards (positive phototaxis)[7,13,30,34,52] or at a steep angle, to about 20 ft. when turbulent transport determines speed and direction or the insects stop climbing and are reported as flying off in the same direction[10–12,15–17,30].

Some species may fly off without delay (aphids, *V. cardui*); others (locusts, *A. monuste*) first make a few, relatively short preliminary flights.

(4) *Duration of migration*. This is partly a species characteristic, probably evolved in relation to survival. Locusts and some Lepidoptera may continue to fly intermittently for many days, covering great distances; others fly for only a few hours (aphids) or even minutes (some Isoptera) before migration ends or flight ceases permanently (Isoptera: some aphids). The exodus flight, however, and sometimes its continuation, appears always to be of relatively great vigour.

(5) *Migratory and other flights*. At present it is not clear if the exodus flight and its more or less immediate continuation are different in quality from other flights which occur later: it is claimed that they are, soundly I think, for Lepidoptera[1–3] and mosquitoes[10–14] at least. But with some insects it is not possible to be certain about this. It seems to me that it is best to make the chronological distinctions first, and that the failure to do this has greatly blurred the migration picture.

(6) *Aggregation*. Insects may aggregate at take-off (locusts) or afterwards (*Danaus plexippus*)[53] or at hibernation or æstivation (for example, Coccinellids). This is a special feature, secondary to synchronization of flight by simultaneous maturation when individuals fly away together but apparently without affecting each other.

(7) *Hibernation and æstivation*. I presume that they are exodus flights which end in hibernation or æstivation, followed later by so-called 'return migration' towards former breeding sites.

(8) *The 'return flight'*. The 'return' flight has been considered a necessity without which a species would lose its breeding sites[3]. This assumes that all the females of the original population transfer to places unsuitable for breeding: this has not been proved. Direction, as well as distance, from the original source vary and migration is dispersive (as compass diagrams show[1–3]); some insects may remain behind[13,37]. The habitat may thus be replenished from within or from directions other than that of the main exodus[54]; there is, however, often a seasonal bias in different directions. The analogy with birds should not be pressed too far.

(9) *Causes of migration*. Current lack of food or space is often said to cause migration, but I postulate that to make the original exodus is the normal individual action of many new flight-mature insects, irrespective of the size of the population, the immediate food supply or space. Shortages of food or space may cause insects to move; such shortages often coincide with a mass exodus, but they are not necessarily cause and effect. Exodus flights are, no doubt, made also by individuals from the smallest possible populations but pass unnoticed. I see migration as an evolved adaptation rather than as a current reaction to adversity.

(10) *The adult as a migrant stage*. The idea that the adult represents a stage the primary function of which is dispersal fits in with my conclusions; for a primary function would be expected to occur as soon as possible once the adult stage is reached, when the insect is fresh.

(11) *Migration and reproduction*. The exodus flight having evolved for recolonization, it therefore precedes oviposition; in fact, in *Aphis fabae*, larviposition is delayed until induced by flight[55], and this may well be the general tendency.

(12) *Migration and dispersal*. The initial exodus flight appears to be generally very active and continuing into the migratory flights lead to dispersal except where they end in aggregations. It remains to find the proportion of the aerial 'plankton' concerned with 'deliberate' post-teneral flights as distinct from being caught up 'accidentally' at other times; but I suspect that post-teneral exodus is the rule with many more species than we realize, though it may be unobstrusive. Insects which do not migrate may well be the exceptional ones.

Conclusions

Mass migratory flights, as commonly recorded, appear to be made primarily by newly emerged adults at the end of the teneral period after moulting from the previous instar and as soon as the insects have full capacity for flight. Commonly, it is the first flight of the new adults, but in some species a number of relatively short flights lead to the exodus flight, which, continuing, becomes dispersive, and takes the insects to new breeding sites, from which new adults of another generation migrate. Exodus flights appear to be made usually by individuals without reference to each other except in special cases (for example, locusts).

This principle does more than repeat that insects leave their breeding places; it says when they migrate, and why they may do so collectively. It distinguishes migration flights chronologically in the first place before attempting to distinguish them behaviourally.

Migration from hibernating or æstivating aggregations of insects also occurs more or less *en masse*, but this is not a general feature; the resemblance to bird migrations (in that a change in behaviour occurs in adults with a previous, different behavioural history) has probably distracted attention from the original post-teneral migration which I postulate is common to all.

The chronology of mass migration now seems more clear: experimental work on migration in many insects might now be planned without waiting for the hitherto unpredictable phenomenon in the field.

This might apply especially to problems of orientation: and to the possible relation of endocrine balance to the active and persistent character of many migratory flights following emergence.

Note added in proof: Since writing this article I have seen P. B. M. Allan's paper (*Entom.*, 75, 147; 1942) in which he, like Piepers (1890), expresses opinions applying specifically to Lepidoptera, which are similar to the views developed above.

BINDING OF A HEPATOCARCINOGEN TO THE STRUCTURAL LIPOPROTEIN OF RAT LIVER: ITS BEARING ON THE IMMUNOLOGICAL THEORY OF CANCER

By J. W. WESTROP and PROF. H. N. GREEN

Cancer Research Unit, University of Sheffield

THE outstanding relevance of specific protein binding by carcinogens to the immunological theory of cancer has been stressed repeatedly since the theory was first proposed[1]. The concept that this specific binding is to a cytoplasmic tissue-specific lipoprotein complex, detectable as tissue-specific antigen, has been steadily developed since that time[2] and there is considerable evidence in its favour.

In hepatocarcinogenesis, central importance has been attached recently to azo-dye binding in the microsomal fraction[3,4]. Since it is known that this fraction, as obtained by differential centrifugation of liver homogenates, includes the cell membrane and ergastoplasm (endoplasmic reticulum + ribonucleic acid granules) it becomes important to decide whether binding of azo-dye to these structures is a factor in the binding found in the fraction as a whole.

Bruemmer and Thomas described a method[5] of obtaining a 'ghost cell' preparation from calf liver and showed it to be an insoluble lipoprotein with a similar chemical composition to an insoluble lipoprotein obtained by Smith *et al.*[6] by differential centrifugation of homogenates. It is thought to represent the structural substance of the cell, that is, the endoplasmic reticulum. Using this method[5], we have obtained a ghost cell preparation from the livers of control rats and rats injected with azo-dye, and confirmed that it is an insoluble lipoprotein. We have also shown, by analysis[7] for bound dye, that firm binding to the protein of this lipoprotein does in fact occur. It is seen (Table 1) that in acute experiments, binding by the hepatocarcinogen, 3′-methyl-4-dimethylaminoazobenzene, is relatively considerable. On the other hand, using the feebly carcinogenic 4′-methyl-4-dimethylaminoazobenzene and the non-carcinogenic 2-methyl compound, no more than a possible trace of bound dye in the ghost cell substance was found. A repeat experiment did, however, show some, though less, binding with both compounds. Under these experimental conditions the binding is not therefore specific to a carcinogen. Feeding of 4-dimethylaminoazobenzene for a long period resulted in the production of enlarged and grossly abnormal livers showing early neoplastic changes. No bound dye was detected in the ghost cell preparation from these livers.

The yield of ghost cell substance, expressed as percentage of fresh liver, from all the rats injected with azo-dye was strikingly reduced. Only in the case of the repeat experiment with 4′-methyl-4-dimethylaminoazobenzene and the 2-methyl compound could this reduced yield be ascribed, and even then only partially, to decreased cellularity of the liver as indicated by the concentration of liver deoxyribonucleic acid. In the other experiments, and notably

Table 1. FIRM BINDING TO THE 'GHOST CELL' SUBSTANCES IN LIVERS OF RATS TREATED WITH AZO-DYE

Exp. No.	Treatment	No. of rats	Time killed	Bound dye: Absorbance/50 mgm. protein	
				Total liver	Ghost cell substance
1	3'-Me-DAB	8	41 hr.	0·183	0·129
2	3'-Me-DAB	6	48 ,,	0·176	0·085
3	4'-Me-DAB	2	48 ,,	0·024	Trace ?
4	2-Me-DAB	1	48 ,,	0·129	Trace ?
5	4'-Me-DAB	7	48 ,,	0·063	0·028
	2-Me-DAB	4	48 ,,	0·122	0·067
6	DAB	3	15 months	—	0·003

Exps. 1–5: Intraperitoneal injection, 20 mgm./100 gm. body weight in arachis oil. Similar numbers of control rats injected with arachis oil only

Exp. 6: Fed 0·06 per cent 4-dimethylaminoazobenzene in stock diet. Similar numbers of controls fed stock diet only.

Absorbance is $\log_{10} I_0/I$, 1 cm. at 520μ for 4-dimethylaminoazobenzene (DAB), 525μ for 2-methyl-4-dimethylaminoazobenzene (2-Me-DAB) and the 3'-methyl compound (3'-Me-DAB), 580μ for 4'-methyl-4-dimethylaminoazobenzene (4'-Me-DAB).

with the 3'-methyl compound, a reduced concentration of liver deoxyribonucleic acid did not accompany the reduced yield of ghost cell substance.

It may perhaps be significant that there was a reduction in ghost cell substance in the 'neoplastic' livers resulting from long-term feeding with 4-dimethylaminoazobenzene. The livers from dye-fed rats were about twice the size of the controls, which might reflect a very low content of ghost cell substance in the neoplastic cell itself. Incidentally, the higher yield of ghost cell substance in this experiment was due to a less rigorous application of the extraction procedure in a first trial of the method. The reduced yield of ghost cell substance from the livers of rats injected with 3'-methyl-4-dimethylaminoazobenzene was accompanied by a reduced concentration of ribonucleic acid in the liver, which was most apparent when the animals were killed 48 hr. after injection of the dye. Since much of the cellular ribonucleic acid is associated with the endoplasmic reticulum to form the ergastoplasm, it would appear that dye injection has produced a loss in both components. This acute loss does not appear to be related to carcinogenic potency.

During the course of the present work, it was reported[4] that following feeding to rats, 3'-methyl-4-dimethylaminoazobenzene was firmly bound to the liver ergastoplasm and exclusively to the 'insoluble residuum' fraction thereof. It seems to us probable that this fraction and our ghost cell preparation represent the same cellular substance, that is, the structural lipoprotein of the endoplasmic reticulum, and that we have confirmed in another, possibly more direct, way that binding of carcinogenic azo-dye to this substance occurs. It is also stated in the report[4] already mentioned that single massive doses of dye may decrease the activity of (liver) glucose-6-phosphatase, an enzyme located in the 'insoluble residuum' fraction. If this is due to loss of endoplasmic reticulum, it would be in line with our finding of a diminished yield of ghost cell substance.

Table 2. EFFECT OF AZO-DYES ON THE YIELD OF 'GHOST CELL' SUBSTANCE AND CONCENTRATION OF NUCLEIC ACIDS IN RAT LIVER

Treatment	Dry liver/wet liver (per cent)	Yield ghost cell substance (per cent)	Composition of ghost cell substance			Liver nucleic acid conc.: change in dye group vs. control	
			Phosphatide (per cent)	N (per cent)	P (per cent)	RNA (per cent)	DNA (per cent)
3'-Me-DAB	23·2	0·30	—	—	—	−17·2	+14·1
Control	23·0	0·83	13·7	10·5	0·90

Control	—	2·45	10·0	9·3	0·83		

* Alcohol extractable only.

† Corresponding figures for additional groups treated similarly were −30·1 and +11·0 respectively.

Our results indicate that binding occurs in the region where tissue-specific antigen(s) is located. A liver microsomal sub-fraction containing a large proportion of the microsomal protein and phospholipid and thought to be a lipoprotein forming an integral part of the endoplasmic reticulum was shown by Vogt[8] to contain all, or nearly all, the tissue-specific antigen. Our preliminary results indicate that the major portion of firmly bound dye in the microsomes after injection of 3'-methyl-4-dimethylaminoazobenzene is in this fraction which contains nearly all the microsomal phosphatide (now completely confirmed in each of four experiments). This, together with the earlier findings, make it highly probable that tissue-specific antigen is involved in the binding process. The question of specificity must remain open until we know whether there is a big quantitative difference between carcinogens and non-carcinogens either in immediate binding, or in the time it persists, or both. However, present results, together with preliminary work on a transplantable hepatoma, indicate that the microsomal lipoprotein complex responsible for binding may be lost during carcinogenesis, since no binding occurred in the late stages of the process nor in the hepatoma. Failure of carcinogenic dye to bind with the soluble protein fraction from chemically induced hepatoma[9], whereas it shows firm binding in normal liver, may be secondary to the deficiency of tissue-specific antigen postulated by us. According to Hultin[3], primary binding is in the microsome fraction, followed by the release of metabolic products into the cytoplasmic fluid, which are then trapped by soluble protein components. If this is so, then in the absence of microsomal binding so-called 'specific' binding to the soluble protein fraction would not occur.

We have for some years[2], on the basis of much varied work, maintained that the cancer cell lacks in some degree cytoplasmic tissue-specific antigen which results in a loss of immunological identity as a tissue. This results in failure of certain (for example, 'scavenger') cells to recognize displaced cells, and in cancer cells lacking the receptors to recognize humoral (for example, hormonal) controls. The cancer cells can therefore no longer be fully integrated into an organized tissue or into the whole organism. The mechanism of loss of tissue-specific antigen doubtless varies greatly, but in chemical carcinogenesis immune attack on haptene-bound tissue-specific antigen may be important[3]. Even if this is not so, the basis of the immunological theory would not be affected.

We have previously suggested[10] that the tissue-specific antigens are membranous lipoprotein complexes and indicated how their loss could account for known alterations in the surface properties of the cancer cell. The concept that cellular affinities (that is, the forces binding like cells to like) are mediated through antigens on cell surfaces is supported by the work of Spiegel[11], who prevented re-aggregation of marine sponge and amphibian embryonic cells by treatment with specific surface-active antibodies. The fact that exposure to a carcinogen has a somewhat similar effect on marine sponge cells[12] favours the idea that surface antigens are involved in carcinogenesis. We are now getting a clearer picture of the site and nature of such antigens and indications of how carcinogenic chemicals and agents of many different kinds interact with them and cause their loss[13].

There is evidence that the ergastoplasm is concerned with the synthesis of proteins peculiar to that cell, and ideas suggesting that differentiation and structure are controlled by self-replicating particles located in the ergastoplasm and linked to nuclear genes by it, have some experimental support[14]. The present findings provide evidence that carcinogens are able to bind firmly to the cell framework. It remains to be seen whether there is in this respect a quantitative, or even qualitative, difference between carcinogens and related non-carcinogens. If there is, and absence of such binding in cancer tissue is confirmed, the idea that deficiency of tissue-specific antigens and neoplasia are synonymous terms will receive further support.

THE BIOCHEMISTRY OF THE EYE*

By DR. ANTOINETTE PIRIE

Nuffield Laboratory of Ophthalmology, Oxford

BIOCHEMICAL processes in the tissues of the eye are as diverse as in any other organ, and the functions of transmission of, and sensitivity to, light add special complexities. Size and shape must be controlled rigidly in order that the eye can act as an optical instrument, the tissues must be transparent, which means that they must be avascular, and the light-sensitive pigments in the retinal cells must be backed by the light-absorbing melanin of the choroid. Cornea, lens and vitreous body are light transmitters and focusers; the retina is the light-receiving and light-sensitive part of the eye.

Cornea and Lens

Recent experiments have shown that the clarity of the cornea depends upon its metabolism, which regulates the ionic balance. If respiration of the epithelium of the cornea is inhibited by fitting a type of contact lens, the epithelial cells swell and water accumulates in the fibrous stroma, thus making the cornea optically imperfect. Presence of oxygen beneath the contact lens prevents this swelling. Similar swelling occurs if the cornea is cooled or stored anaerobically or in the absence of glucose, but can be reversed when the tissue is re-warmed in presence of oxygen and glucose. A degree of swelling that might be unnoticeable in another tissue can distort the optical perfection of the cornea.

The cornea consists of three parts—epithelium, collagenous stroma and endothelium. The stroma is, in most animals, the largest part, but the epithelium has the most active metabolism. The cornea is avascular and oxygen is supplied by diffusion from the air, and, together with other nutrients, from the aqueous humour and surrounding tissues. The metabolism of glucose by the corneal epithelium appears to be similar to that of other tissues. The Q_{O_2} is 6–8, which is comparable to liver; cytochrome oxidase can be demonstrated histologically and cyanide inhibits respiration almost completely. Anaerobic glycolysis and some aerobic glycolysis occur. The enzymes of the citric acid cycle are present and glucose is also directly oxidized by the pentose phosphate pathway.

Glucose breakdown is the main source of energy in both cornea and lens. The relative importance of different paths of glucose breakdown has been studied in both tissues by Kinoshita and Wachtl using glucose labelled with carbon-14 on C_1 or C_6 or uniformly labelled on all carbons. In these avascular tissues anaerobic glycolysis is, as one might expect, the main path. The corneal epithelium glycolyses 65 per cent of all glucose metabolized and oxidizes 35 per cent, most of it by direct oxidation through the pentose phosphate route. The lens, which is much less active metabolically than the cornea, glycolyses almost all glucose used. The citric acid cycle is almost inactive in lens and any oxidation of glucose takes place by direct oxidation of C_1 through the pentose phosphate path. This oxidation is accompanied by reduction of triphosphopyridine nucleotide, and systems which can re-oxidize this coenzyme have been sought in both cornea and lens. Kinoshita found that the corneal epithelium contains a lactic dehydrogenase that will use reduced triphosphopyridine nucleotide, reducing pyruvic to lactic acid, and that addition of pyruvate anaerobically to cornea stimulates direct oxidation of glucose. Such a system may also be active in lens. Both tissues also contain a high concentration of reduced glutathione and glutathione reductase, which uses reduced triphosphopyridine nucleotide as coenzyme; but no system oxidizing glutathione has yet been found.

---

* Substance of two lectures given in University College, London, on February 29 and March 7, 1960.

The corneal stroma consists of fine uniformly arranged collagen fibres embedded in a matrix of mucopolysaccharides and mucoproteins. As these substances occur in the cornea unmixed with other fibrous proteins or with blood vessels it seems a suitable tissue in which to study collagen and mucopolysaccharide formation. Experiments have shown that repair of collagen in the cornea requires ascorbic acid. Three mucopolysaccharides are present—keratosulphate, a polymer of N-acetylglucosamine, galactose and sulphate, chondroitin sulphuric acid, a polymer of N-acetylgalactosamine, glucuronic acid and sulphate and the non-sulphated polysaccharide chondroitin. Cornea, both *in vivo* and *in vitro*, will incorporate sulphur-35 labelled inorganic sulphate into mucopolysaccharides. The uptake is much reduced in scorbutic guinea pigs.

The lens cells are derived from embryonic ectoderm. A small clump of cells grows into the optic cup, rounds itself off and becomes detached from the outer surface. By the time the human embryo is 2 cm. long this little clump has surrounded itself with a capsule which is impermeable to cells and to proteins, and the lens exists for the rest of life cut off from blood vessels and nerves, suspended radially in the eye by the suspensory ligament and bathed by the aqueous and vitreous humours. The adult lens has a dry weight of 35 per cent and nearly all of this is protein. The protein of the lens is not species specific. Common antigens are present in the lenses of all mammals examined, and man and animals can form antibodies to their own lens proteins. Escape of protein from a cataractous lens occasionally leads to development of sensitivity to lens protein and this can cause an intraocular allergic reaction. Until recently the lens was thought to contain only three major proteins, but with advance in electrophoretic techniques thirteen protein fractions have been separated and five fractions crystallized.

Senile cataract occurs throughout the world in man and animals but the biochemical changes are not known. A form of experimental cataract in which some of the biochemical changes are known is that produced in young rats by feeding high concentrations of galactose or xylose or by inducing diabetes with alloxan. R. van Heyningen has found that enzymes are present in the normal lens which will convert glucose to fructose by way of sorbitol. Sorbitol, present in traces in normal lens, accumulates in the lens of the diabetic rat, and the corresponding polyols, dulcitol and xylitol, accumulate in the lens of the rat fed galactose or xylose. The concentration of dulcitol may reach 2 gm./100 gm. lens after 1–2 days on a diet of 35 per cent galactose before any sign of cataract has appeared.

Cataract due to excess galactose also occurs in man. Some babies cannot metabolize galactose, do not thrive on milk and, among other signs of illness, may develop cataracts. Kalckar has found that galactosæmia is an inborn error of metabolism and that these babies do not have the enzyme galactose-1-phosphate uridyl transferase in their tissues, and their red blood corpuscles contain galactose-1-phosphate. Schwarz and Golberg found traces of galactose-1-phosphate in the fully cataractous lenses of galactose fed rats, and Lerner found that lenses from a galactosæmic infant had a low galactose-1-phosphate uridyl transferase activity. Whether block of galactose breakdown at the dulcitol-level with early high accumulation of dulcitol or block of the further metabolism of galactose-1-phosphate causes lens opacity to develop is still not clear.

Such cataracts are very rare in man, but senile cataract is still listed as the largest single cause of blindness in the world as a whole, in spite of the fact that the blindness can be relieved by surgical removal of the cataractous lens.

The Vitreous Body

The vitreous body fills the space between the lens and retina and can be considered as an extremely tenuous connective tissue. Although it is 99 per cent water it is a surprisingly stable jelly-like structure which does not dissolve when suspended in saline. A fibrous insoluble residue was described by Mörner in 1894, who suggested that it might be collagen, and this was confirmed using chromatographic and X-ray analysis. Electronmicrograms show very fine uniform fibres which occasionally show a cross-striation of 640 Å., in the posterior part of the vitreous body, while coarser fibres are present near the lens where the vitreous body is very firmly attached to the retina and outer coats of the eyeball. When the fibrous part is separated by centrifugation or filtration a clear viscous fluid remains, the vitreous humor, from which hyaluronic acid was first isolated by Meyer and Palmer in 1934. The stability of the vitreous body depends on the network of collagen fibres permeated by polymerized hyaluronic acid. The concentration of hyaluronic acid in the vitreous of cattle is about 400 mgm./l., and the concentration of fibrous protein 150 mgm./l., yet together, these large molecules, even in these low concentrations, form a surprisingly stable structure.

The Retina

The retina, like the brain from which it is derived embryologically, has a very active metabolism. The Q_{O_2} is about 10, and glycolysis proceeds both aerobically and anaerobically. Oxidation of glucose takes place by the pentose phosphate path and by the citric acid cycle, judged by formation of carbon dioxide from glucose labelled with carbon-14 on C_1 or C_6. But in studies of yields of radioactive lactic acid, carbon dioxide or other intermediates the fact that retina will actively incorporate carbon dioxide into malate must be remembered. Addition of pyruvate to retinal tissue stimulates direct oxidation of glucose presumably through stimulation of reactions which re-oxidize reduced triphosphopyridine nucleotide, thus supplying triphosphophyridine nucleotide for glucose oxidation. Such reactions could be the formation of malate from pyruvate plus carbon dioxide catalysed by the malic enzyme or reduction of pyruvate to lactate catalysed by a lactic dehydrogenase.

Attempts have recently been made to correlate the high rate of retinal glycolysis with maintenance of light sensitivity, and to determine metabolic changes when the retina is illuminated. Injection of iodoacetate in many species of animals causes an almost immediate fall in the electrical response of the retina to light and this is followed by a progressive fall in glycolysis with degeneration of those cells in the retina which contain light-sensitive pigments. But further work has shown that iodoacetate inhibits other processes in the retina besides glycolysis. No change has been found in respiration, in adenosinetriphosphate, deoxyribonucleic acid or ribonucleic acid when the retina is illuminated.

The main biochemical study of the retina has always been study of the light-sensitive pigments themselves. This brief review can discuss only one class, namely, those which are contained in the rod cells of vertebrate retinas and are thought to be the basis of vision in dim lights where colours are not appreciated. These pigments, the rhodopsins and porphyropsins, are lipoproteins with carotenoid chromophores, the carotenoid being retinene A_1, the aldehyde of vitamin A_1, or retinene A_2, the aldehyde of vitamin A_2. It is interesting that the first connexion between vitamin A and visual pigments came from study of human and experimental night blindness and that later biochemical work showed the vitamin to be a part of the pigment molecule. Rhodopsin can be isolated from the rod cells by extraction with digitonin with which it forms a soluble complex. It is a red pigment which fades to a yellow when exposed to light. This red pigment was first seen in the frog retina by Boll in 1876, who noticed that it faded in light but was re-formed if the live animal or separated eye was left in the dark.

The breakdown of rhodopsin by light and its re-formation in darkness has been studied by examination of changes in the absorption spectrum. Mammalian rhodopsin has an absorption maximum at 500 mμ, which is also the wave-length of light to which the mammalian eye is most sensitive. Change in absorption at 500 mμ measures change in rhodopsin. The primary action of light can be studied by determining change at very low temperatures, − 70° C., where thermal reactions are stopped. Such experiments show that light does not, strictly speaking, bleach rhodopsin but only changes the point of maximal absorption very slightly to the blue. Subsequent reactions which occur in light or in the dark cause more profound changes with release of retinene. Recent work of Wald and Hubbard has suggested that the retinene present in rhodopsin is a particular 11-*cis* stereoisomer and that the action of light is to change this isomer to the all-*trans* form while leaving it still attached to the protein. Vitamin A and retinene in other parts of the body are the all-*trans* isomers, but the pigment epithelium in mammalian eyes and the eyes of some marine crustaceans contain 11-*cis* retinene. The mechanism of formation of this isomer in the eye is not clear. Wald found it less effective than the all-*trans* isomer in promoting regeneration of rhodopsin in the retina of the vitamin A-deficient rat.

Examination of the density of rhodopsin in the living eye has shown that visual sensitivity is not related directly to rhodopsin concentration. Bleaching half a per cent of the total rhodopsin reduces sensitivity three-thousand-fold. Probably neural factors as well as pigment concentration are involved.

Apart from the light-sensitive pigments of the visual cells there are other pigments in the eye that modify the light stimulus received. For example, there is a yellow pigment, probably the carotenoid xanthophyll, at the macula, where vision is most acute in the human eye. This absorbs about 60 per cent of all incident blue light. The retinal pigment epithelium or choroid of many fish, amphibians and at least one reptile contains fluorescent pterins, and similar parts of the eyes of other species of fish and some mammals are rich in riboflavin. The most extreme example is the eye of the lemur, *Galego crassicaudatus*, in which there is a layer of crystals of riboflavin immediately behind the visual cells. This mirror will both reflect light and, through its fluorescence, will transform short-wave blue light to light of longer wave-length (520 mμ) to which rhodopsin is more sensitive.

Many animals have elaborated mirrors behind their retinas or on their irises. Carnivores have a layer of crystals of zinc cysteine ; and in the silver fox the zinc concentration of this part of the eye may reach 16 per cent of the dry weight. This is also the basis of the eye shine of dogs and cats. Fish and amphibians lay down crystals of guanin as a mirror in their eyes as in their scales (fish silver), while lemurs have crystals of riboflavin. The biochemical processes whereby these substances are concentrated to such an extent that they crystallize have yet to be investigated.

The study of both the specialized and the general biochemistry of eye tissues is only just beginning to expand. It is a fascinating study, and should lead to a clearer understanding of normal and abnormal processes in the eye as well as giving information which is interesting in connexion with the metabolism of other tissues.

OBITUARIES

Prof. H. W. B. Skinner, F.R.S.

HERBERT SKINNER, Lyon Jones professor of physics in the University of Liverpool, died suddenly in Geneva on January 20, at the age of fifty-nine, leaving a wife and daughter. His death was a great shock to a wide circle of friends and colleagues, for he was well known and liked far beyond his own University.

He was educated at Rugby and Trinity College, Cambridge, and worked under Rutherford at the Cavendish Laboratory until 1927, when he joined Tyndall at Bristol. He was elected to the Royal Society in 1942 in recognition of his work on the soft X-ray spectroscopy of metals.

Early in the War, Skinner worked on radar at the Telecommunications Research Establishment, which was a remarkably successful amalgamation of academic, industrial and Government scientists working in close liaison with the communications industry and the Royal Air Force. Skinner was one of the bright spirits of this enterprise and certainly contributed much to its success. He left in 1943 to join the atomic weapons work under the Department of Scientific and Industrial Research, and went to California as a senior member of the British group working with E. O. Lawrence and his colleagues on the electromagnetic separation of uranium isotopes.

Skinner returned to act as deputy to Sir John Cockcroft, who was still in Canada, in setting up the Atomic Energy Research Establishment at Harwell. He and a few colleagues began the creation of a great research laboratory from an empty R.A.F. station on the edge of the Berkshire Downs. Looking back now, it is remarkable that such impressive progress was made in those early years, when conditions were so difficult. Skinner's contribution, first acting in Cockcroft's absence and later as one of his able lieutenants, was a most important one. His particular personal creation was the General Physics Division which, organizationally, could have no logical justification but was a reflexion of his own wide interests and was extremely productive. Under his personal supervision came the synchrocyclotron, cloud chamber and nuclear emulsion work, synchrotrons, linear accelerators and electronics instrumentation, X-ray and neutron diffraction, isotope separation and mass spectrometry, and, later, extra-mural work on plasma physics. All this work prospered and, with the growth of Harwell, some found homes in new divisions.

Four years later, when chief physicist at Harwell, Skinner was appointed to succeed Sir James Chadwick at Liverpool. There he had further opportunity to exploit his talent for construction, because Chadwick, having created a flourishing school of nuclear physics around one of the first cyclotrons in Europe, had undertaken the construction of a new research laboratory centred on a 156-in. synchrocyclotron. This large project was in an early and critical stage, but was brought to a highly successful conclusion with the help of Chadwick's former colleagues and new men brought in by Skinner. Unlike Chadwick, Skinner was not primarily a nuclear physicist, and he appointed J. M. Cassels as professor of experimental physics. Liverpool became the home of a powerful school of high-energy physics, and the research work more than kept pace with the general growth in the universities. The small cyclotron, together with a Cockcroft–Walton generator, enabled the traditional nuclear physics school at Liverpool to grow in size and output to such good effect that one of Skinner's last acts was to undertake the installation of a tandem electrostatic generator for further expansion in this field. This machine is still being manufactured, and it is tragic that Skinner will not see it installed. A new and impressive building, the Chadwick Physics Laboratory, for teaching and research was completed recently under his guidance.

Skinner was active in the work of the European Organization for Nuclear Research (CERN) and was the senior British consultant in the 600-MeV. synchrocyclotron project. He was chairman of the CERN Panel of the Department of Scientific and Industrial Research, concerned with British participation in CERN'S work, and served on the Nuclear Physics Sub-Committee. He remained keenly interested in atomic energy, and was a consultant to the Atomic Energy Authority and a member of the *Nimrod* Project Committee. The National Institute for Research in Nuclear Science has good reason to be grateful for his advice and help on numerous occasions, and he was an active and provocative member of several committees of the Institute. He brought his laboratory into the national Liquid Hydrogen Bubble Chamber project sponsored by several British universities.

Herbert Skinner was devoted to physics and to physicists, and was generous with his time and energies. He hated red tape and sometimes alarmed administrators. Unconventional, persistent in argument and often disconcerting in management, he was also sincere, gentle and kind to an extent not always understood by his critics. He and his wife Erna were generous in hospitality, and their home was often crowded with guests. The affairs of physicists are duller without him.

T. G. Pickavance

Prof. Marcel Schein

On February 20, at the height of his scientific career, Marcel Schein died in Chicago, Illinois. With him disappeared a most brilliant, able and imaginative scientist whose work is destined to leave an enduring mark in the physics of our century.

Marcel Schein was born in Tresten, Czechoslovakia, on June 9, 1902. After studying in Prague, Vienna, Würtzburg and Zurich, he received a doctorate in physics at the University of Zurich in 1927. His first academic appointment was that of assistant in physics in that University. Between 1929 and 1930 he spent a year in Chicago on a Rockefeller Fellowship. He then returned to Zurich as a *docent*, a position which he held until 1935, when he was appointed professor of physics at the University of Odessa. In 1938, Marcel Schein went to settle permanently in the United States, at the invitation of Prof. A. H. Compton. He joined the University of Chicago where he remained until his death, holding various positions until, in 1946, he was appointed professor in the Department of Physics and in the Institute of Nuclear Studies. In 1927, while in Zurich, he married the former Hilde Schoenbeck, who was working as a Ph.D. candidate in the Physics Department. From this marriage he had a son, Edgar, who is now on the faculty of the School of Industrial Management at the Massachusetts Institute of Technology.

In the early years of his scientific career, Marcel Schein made some valuable contributions to the physics of X-rays. He is best known, however, for his work in cosmic rays, which he began after moving to Chicago in 1938. At that time it was known that the primary radiation consisted, at least to a large extent, of positively charged particles. The possibility that these particles might be protons had been suggested; however, there was no direct experimental evidence to support this assumption. Indeed, the prevailing view was still that primary cosmic rays were for the most part positive and negative electrons. During 1938–41, Marcel Schein conducted a series of balloon experiments in which he studied the physical properties of cosmic-ray particles in the highest layers of the atmosphere and was able to show that these particles did not behave in at all the way that high-energy electrons were known to behave. He concluded that electrons did not appear in any appreciable amount among primary cosmic rays, and that the incoming radiation consisted most likely of protons[1].

These experiments remain one of the milestones of cosmic-ray research. However, they were only the beginning of Marcel Schein's work in this field of science. Soon his interest became focused on the most energetic particles present in the primary cosmic radiation and on the remarkable and unbelievably intricate processes that occur when these particles strike atomic nuclei. Marcel Schein was a pioneer in the study of nuclear interactions at energies far exceeding those provided by man-made machines. At the time of his death, he had just returned from an expedition to the Caribbean where, in an effort to extend further and improve the experimental data on high-energy interactions, he had flown the largest stack of nuclear emulsions ever used in any experiment. This stack, which is now being processed, will undoubtedly contain invaluable data the analysis and interpretation of which will keep many physicists busy for a number of years.

Marcel Schein was keenly interested in international scientific collaboration. He travelled extensively in foreign countries, providing great stimulation through his lectures and his informal contacts with scientific workers. He participated most actively in practically all major international conferences dealing with subjects within his field of interest. His last experiment, which I mentioned before, was a truly international venture, with a large number of laboratories, both in the United States and abroad, participating in the analysis of the experimental results.

Marcel Schein was, in many ways, a remarkable man. For him science was a passionate search for the new and the unknown, involving all his scientific skills, as well as his deepest emotions. His sharp mind, his keen intuition, his irresistible enthusiasm and his intense personality will be long remembered by his many friends, pupils, and professional associates in all parts of the world. BRUNO ROSSI

Prof. G. P. Mazumdar

PROF. G. P. MAZUMDAR died suddenly on November 21. He was born on February 18, 1894, at Gopalnagar in the District of Pabna, North Bengal (now in East Pakistan), the third son of Kali Charan Mazumdar, a wealthy landlord and Zeminder of the district. After obtaining his B.Sc. at the University of Calcutta in 1913, he joined the teaching staff of the Botany Department, Presidency College, Calcutta. He later obtained his B.A. (1916) and M.Sc. in botany (1915), standing first in order of merit, and in 1917 the B.L. degree from the same University. He was eventually appointed a professor of botany in the Bengal Educational Service in the Presidency College, Calcutta, and from 1928 became one of the postgraduate lecturers in botany at the University of Calcutta. In 1938 he went on study leave to England to work on plant anatomy in the University of Leeds under the late Prof. J. H. Priestley and obtained the degree of Ph.D. in 1940. He retired from the Government service in 1949; but his services were soon requisitioned by the Government of West Bengal for the organization of honours teaching in botany in the Government College, Darjeeling. In December 1951 he was appointed professor of botany and head of the Biology Department, University of Dacca, in East Pakistan, and retired in October 1954. While in Pakistan, he acted as the chairman of the Commission of Courses of the Karachi University and presided over the Section of Biology at the annual session of the Pakistan Association for the Advancement of Science in January 1955. In 1945 he presided over the Section of Botany at the thirty-second Indian Science Congress. He also presided over the Section of Technical Sciences at the All-India Oriental Conference some few years back. He was elected a Fellow of the Indian Academy of Sciences, Bangalore, and National Institute of Sciences of India (1945). He was for a long time connected with the Indian Association for the Cultivation of Science, now at Jadavpur, Calcutta, both as a member and a treasurer. He was also member of other Indian learned societies.

Prof. Mazumdar published a large number of scientific papers in numerous journals throughout the world and several scientific Bengali primers, especially in botany. His writings for children on scientific subjects and botany in Bengali have evoked admiration. He also dealt with botany in ancient India in several books and papers. His "Vanaspati" earned for him the Griffith Memorial Prize of the University of Calcutta in 1925. His "Upavana Binoda" (dealing with horticulture in ancient India) was published in 1938. He published other works on the history of botany. The Asiatic Society awarded him the P. Bruhl Memorial Medal in 1955 for his outstanding researches in botany.

R. M. DATTA

NEWS and VIEWS

Botany at Cambridge: Prof. G. E. Briggs, F.R.S.

ON September 30, Prof. G. E. Briggs will retire from the professorship of botany in the University of Cambridge. Since he succeeded Prof. F. T. Brooks in 1948, he has maintained the notably wide range of teaching and research in the Botany School and has fostered expansion in several branches of the subject. The Department has flourished under his direction, and has benefited greatly from his example of easy friendliness. As a physiologist he has always believed in the value of a quantitative and critical approach both in teaching and research, and his lectures were planned not only to show this but also to indicate the weaknesses of many currently accepted generalizations. He is a brilliant teacher, and for those undergraduates and research students who could rise at least part-way towards his high standard, his lectures and supervision provided a never-to-be-forgotten education. His researches on enzyme kinetics, on growth and photosynthesis early brought him a world-wide reputation as a critical and original thinker. More recently he has entered a new field of research, the biophysics of the plant cell, and his success in this work has drawn to him a flourishing group of research students. In 1952 he became president of St. John's College, but he never allowed the duties of this post to curtail the time he gave to the Botany School.

Prof. H. Godwin, F.R.S.

DR. H. GODWIN, reader in Quaternary research at Cambridge, who has been appointed to succeed Prof. Briggs, is known to a large number of former Cambridge students as an able and enthusiastic teacher of botany at all levels. Outside Cambridge, he may be best known for his large book on the Quaternary history of the British vegetation. His first research was, in fact, in pure plant physiology with Dr. F. F. Blackman, but from early days the inspiration of A. G. Tansley led him to work at Wicken Fen and eventually ecology took up his whole time. Study of fluctuating water-level in the peat and of the effects of this and of cutting reeds on fen vegetation soon directed his attention to the history of this vegetation in the immediate past, and to actual changes in this locality rather than general seral development. Thus he naturally dug in the peat for visible plant remains, and was soon using the methods of pollen analysis worked out not long before by von Post in Sweden. He gradually developed his own blend of the study of pollen, other plant remains and local ecology. He has now a considerable and well-equipped research school. Latterly their work on the more recent peats have been telling such consistent stories that his school have pushed their studies back into the Late Glacial and into the more extensive wilderness of the various Interglacials.

Organic Chemistry in the University of New South Wales : Prof. S. J. Angyal

The newly created chair of organic chemistry in the University of New South Wales (formerly the New South Wales University of Technology) has been filled by the appointment of Dr. S. J. Angyal, formerly associate professor in the University. Prof. Angyal was educated in Hungary and migrated to Australia at the beginning of the War. As lecturer in the University of Sydney, he carried out research on the Sommelet reaction. In 1952, as Nuffield Dominion Travelling Fellow, he spent a year in Sir Alexander Todd's laboratory in Cambridge. He was visiting professor in the University of California in Berkeley in 1957. In the following year he was awarded the H. G. Smith Memorial Medal by the Royal Australian Chemical Institute. Prof. Angyal takes great interest in stereochemistry, and has made important contributions to the chemistry of the inositols. At present he is engaged in work on the application of conformational analysis to carbohydrate chemistry.

Radio Research in Britain : Dr. J. A. Saxton

Dr. J. A. Saxton has been appointed deputy director of the Radio Research Station, Slough (Department of Scientific and Industrial Research), in the grade of deputy chief scientific officer. This appointment is opportune, as he will serve for a period of six months under the present director, Dr. R. L. Smith-Rose, before the latter is succeeded by Mr. J. A. Ratcliffe on October 1 (see *Nature*, February 6, p. 353). Dr. Saxton joined the scientific staff of the Radio Division of the National Physical Laboratory in 1938, and has been responsible for carrying out a considerable programme of research in the propagation of very short radio waves over the ground and through the troposphere. He has studied the electrical properties of gases, water vapour, and water, at very high radio-frequencies, and applied the results to an understanding of the refraction of radio waves transmitted through the lower atmosphere. During 1945, and again in 1950, he was seconded to the United Kingdom Scientific Mission in Washington for liaison duties in radio physics and engineering; and he has made extensive visits in the United States and Canada in connexion with research in radio wave propagation and allied problems. He has been an official delegate of the United Kingdom at meetings of the International Scientific Radio Union (U.R.S.I.) and the International Radio Consultative Committee (C.C.I.R.) in London, Geneva, The Hague, Boulder (Colorado) and Los Angeles. Dr. Saxton has attended senior staff courses at the Administrative Staff College, Henley, and at Peterhouse College, Cambridge. For the past five years. he has been a senior principal scientific officer, and head of a division of the Radio Research Station, and so is well qualified and experienced for the new post of deputy director of the Station.

Atoms for Peace Awards for 1959 and 1960

Drs. Leo Szilard, professor of biophysics in the University of Chicago, and Eugene P. Wigner, Thomas B. Jones professor of mathematical physics, Princeton University, are to share the 1959 Atoms for Peace Award; and Dr. Walter H. Zinn, formerly director of the Argonne National Laboratory, and now vice-president of Combustion Engineering, Inc., and Dr. Alvin M. Weinberg, director of the Oak Ridge National Laboratory, will share the 1960 Award. All have been active in the development of nuclear reactors. Each will receive a gold medallion and will share equally in the combined honorarium of 150,000 dollars. The Awards will be presented at a ceremony to be held at the National Academy of Sciences, Washington, D.C., on May 18. In making the announcement, Dr. James R. Killian, jun., chairman of the Trustees of Atoms for Peace Awards, said:

"The Trustees believe the development of the nuclear reactor is one of the great advances in man's capability for using atomic energy for peaceful purposes. It gives the world a new source of energy with which to meet the growing requirements of modern society for power to run its machines. As a source of radioisotopes, it is now providing science and industry with new possibilities in research and control, as well as with new products. The transformation of a highly complex, theoretical concept of 1939 to the multitude of reactors operating to-day in research and in commercial establishments is a major achievement of modern science and engineering. The men who are selected for recognition by this Award have been leaders in that transformation. Dr. Szilard and Dr. Wigner, both working in the area of nuclear physics, were early advocates of a concerted effort to study the possibilities of nuclear chain reactions. Their interest and concern resulted in the well-known letter of the late Albert Einstein to President Roosevelt which noted that "the element uranium may be turned into a new and important source of energy in the immediate future". These two men held an influential place in the work which resulted in the first nuclear chain reaction and in the subsequent applications of that significant development. Dr. Zinn and Dr. Weinberg participated in the early work and have continued to make important contributions in the field of reactor design and in the administration of research and development efforts in this area."

The Atoms for Peace Award was established as a memorial to Henry Ford and his son, Edsel, in response to President Eisenhower's 1955 appeal at Geneva for international efforts to develop nuclear energy for peaceful purposes. It is granted "solely on the basis of the merit of contribution, wherever found in the world and without regard for nationality or politics".

Ballistic Missile Early Warning Station at Fylingdales Moor

The debate in the House of Commons on March 25 on Mr. T. Driberg's motion that to establish a ballistic missile early warning station on Fylingdales Moor is contrary to the spirit of the National Parks and Access to the Countryside Act, 1949, is chiefly of interest for the reply of the Under-Secretary of State for Air, Mr. W. J. Taylor. Mr. Driberg argued that unless the National Parks Commission was consulted in advance, consultation meant nothing, and he also alleged that some scientific opinion held that the station could not be equipped with a system of radar detection capable of identifying ballistic missiles with certainty. Mr. Taylor repeated the assurance given by the Secretary of State for Air on March 3 that no alternative area was available in Britain and said there was to be very full discussion of the detailed proposals between representatives of the Air Ministry, the National Parks Commission and the Council for the Preservation of Rural England, and while the siting of the radars themselves could not be modified, he hoped that by careful choice of design and attention to landscaping details, the appearance of the completed station should be such that the disturbance to the natural landscape would be generally acceptable. On the certainty of detection, Mr. Taylor said that the opinion quoted was not sustained by the advice of the distinguished scientists who had advised the Government on the project and that in the view of those scientists the system would work. He was informed that there was no difficulty in distinguishing between ballistic missiles and artificial satellites and that the possibility of confusion between a missile trajectory and an ionization trail was so remote that for practical purposes it could be ignored. The Government was satisfied that this system of radar detection was capable of identifying ballistic missiles with very great precision and, moreover, the station was complementary to other methods of obtaining information about hostile intentions and provided the last stage of tactical warning.

Development of Ballistic Missiles

On April 13 the Minister of Defence, Mr. H. Watkinson, in the House of Commons, and the First Lord of the Admiralty, Lord Carrington, in the House of Lords, announced that the Government has been considering the future of the project for developing the long-range ballistic missile *Blue Streak* and has been in touch with the Australian Government about it. The vulnerability of missiles launched from static sites, and the practicability of launching missiles of considerable range from mobile platforms have now been established, and in the light of military advice, the Government has concluded, and the Australian Government has fully accepted, that Britain should not continue to develop, as a military weapon, a missile that could be launched only from a fixed site. The Government is now considering whether the *Blue Streak* programme can be adapted for the development of a launcher for space satellites, and a further statement will be made as soon as possible. There are many other projects for which the range at Woomera will be needed, and a substantial programme of work for that range for some years to come at least is expected.

In reply to further questions Mr. Watkinson said that the cost of the project to date has been about £65 million and that of completing it would be between £500 and £600 million. None of the expenditure would be wasted if it was decided to go ahead with *Blue Streak* as a launcher for a space satellite. The Americans are investing an immense sum of money in space research, both for its military and its scientific and industrial value, and at present Britain could only get into space by the American offer to launch British satellites. *Blue Streak*, in conjunction with *Black Knight*, which has a record of firings practically 100 per cent perfect, is a possible space launching-vehicle, and this combination may give us experience of the utmost military and scientific value.

New Nature Reserve in Scotland

Strathy Bog, an area of 120 acres in the County of Sutherland, has been declared a nature reserve by the Nature Conservancy; this brings the total number of national nature reserves in Scotland to 24 with a total area of 101,809 acres. The new reserve is the least-disturbed part of a vast area of bogland which covers the flat or gently undulating moorlands of this district. The ground is extremely wet, with standing water in the pools throughout the year, and *Sphagnum* moss is prominent in the vegetation, giving a generally spongy surface. In a rich assemblage of bog-plants there are cotton-grasses, sundews, bog asphodel, dwarf birch and bearberry. The area shows certain unusual structural features. Part of the Bog is covered with elongated pools lying parallel to each other, giving the impression that the surface has torn repeatedly under tension caused by the rather fluid mass of underlying peat tending gradually to slide down-hill. Such bogs may thus eventually break up and dry out even when unaffected by human disturbance.

The Nature Conservancy also announces additions to the nature reserve at Rannoch Moor. The original area was 3,485 acres in the north-east corner of the Moor of Rannoch. The new area comprises 200 acres covering a stretch of Loch Laidon and a small area of 19 acres at the southern end of the existing reserve.

International Communications and Scientific Journals

With the rapid growth of new journals the problem of presenting these journals in a form which will make their contents available to readers in other countries becomes more and more acute. To help English-speaking peoples, an increasing number of editors in countries oversea are preparing copies of their journals translated into English. Although this practice is highly commendable from the point of view of English-speaking readers, the journals often fail to make the impact they might because of the inadequacies of the translation. It is extremely difficult to translate the highly technical language of one country into that of another, and, unless special precautions are taken, a translation may produce effects which are not quite what the original research worker had intended. Recent English versions of journals which emanated from France, Czechoslovakia and Japan all indicate that the translations have been carried out by natives of those countries who 'know English well'. Before publication they would have been well advised to submit their publications to English-speaking men of science who also have a good working knowledge of the foreign language concerned. In this way the circulation value of their journals would be considerably enhanced, and many ludicrous statements would be eliminated. Another solution to what is admittedly a most difficult problem might be greater use of an auxiliary language like Interlingua or Esperanto. A world-wide conference to discuss the matter could be of benefit to men of science everywhere.

Abstracting Scientific Information

The Review of the International Council of Scientific Unions for July 1959 contains an article by Prof. E. A. Boutry, secretary of the International Council of Scientific Unions Abstracting Board, describing the work of the Board, its story, ideas, methods and aims, which merits wide reading by scientific workers. Prof. Boutry points out that owing to the rapid increase of the bulk of published scientific information, the probability that printing a paper in a periodical will suffice to ensure that the scientific information it contains will reach the appropriate scientific worker has steadily decreased in recent decades and is likely to continue doing so, nor have editors of abstracting periodicals any certain means of procuring all the literature they should review or learning of its existence. Needless repetition and duplication hamper the work of abstracting periodicals and no mechanical or automatic methods can improve the quality of the literature published or reviewed, or reduce useless duplication. Looking to the future, Prof. Boutry makes various proposals. Authors, he suggests, should voluntarily accept and comply with certain rules in writing their manuscripts. Particularly he advocates submission with the paper of an author's abstracts in two versions, one of which should be written in English or French, composed in accordance with the "Guide for the Preparation and Publication of Synopses" (Unesco). He also deprecates publication of incomplete and incorrect "Letters to the Editor". Editors are asked to agree voluntarily to see that these practices are followed and to waive copyright in respect of such abstracts for members of the Board, while national committees of science and national scientific societies are asked to help in tracking and listing serial or non-periodical publications in their countries and to discourage excessive printing of non-periodical publications.

Carnegie Trust for the Universities of Scotland

The fifty-eighth annual report of the Carnegie Trust for the Universities of Scotland covers the year ended September 30, 1959, in which investment policy has absorbed an exceptional amount of the time of the Executive Committee (pp. iii+73. Edinburgh: Carnegie Trust for the Universities of Scotland, 1960). The new investment policy has substantially improved the income of the Trust, which reached a record high level of £176,564 in consequence. The largest single payment was £33,000 to the University of Glasgow towards the cost of the new arts building, while Edinburgh received £20,000 towards the cost of its new Staff Club. During the year there were on the books two Fellows, three senior scholars and 68 scholars of whom 30 were new appointments, and annual expenditure on the research scheme reached a record level of nearly £27,000. Counting mathematics and geography as arts subjects, forty of the awards were in arts and thirty-three in science; and 22 of the latter were to chemists, including biochemists. Under the new regulations, which discouraged applications from students benefiting from the improvement of local authority bursaries in 1957, while the number of beneficiaries fell from 1,430 in 1957–58 to 568 in 1958–59, the average payment per beneficiary rose from less than £15 to £30 and the total expenditure on fees only fell from £21,500 to just over £17,000. Appendixes to the report include the memorandum of evidence submitted to the Anderson Committee on Grants to Students and the usual reports on the work of Fellows and Scholars and on research grants other than travel grants as well as a list of publications since September 30, 1958, by Fellows, Scholars and recipients of grants. It is noted that three out of the six scholars who have completed their third year of work in chemistry have undertaken post-graduate research in the United States or Canada, but that information suggests that at least half such British research graduates in chemistry eventually return. Assistance given to the Scottish Dictionaries Joint Council was consolidated into an annual grant of £5,000 until 1963 and assistance to Scottish learned societies towards the cost of publications has been restricted to the present level of £2,500 per annum.

Instrument Abstracts

A useful journal for all who work with instruments is compiled by the British Scientific Instrument Research Association (No. 1, Vol. 1, January 15, 1960). It contains details of a wide range of publications in instrument technology with abstracts of many of them. Besides a general section there are sub-sections on astronomy, atomic physics, biology and medicine, chemistry, control, data handling, electricity, electronics, fluid mechanics, geophysics and meteorology, heat, light, magnetism and electromagnetism, materials and design, mechanics, navigation, sound, surveying, and telecommunications. The publications listed have been taken from many countries including France, Germany, Holland, United States and the U.S.S.R. *Instrument Abstracts* is published monthly by Taylor and Francis, Ltd., Red Lion Court, Fleet Street, London, E.C.4. The annual subscription is £4.

U.S.S.R. and the International Geophysical Year

A series of publications concerning various activities in the U.S.S.R. during the International Geophysical Year has been issued. Included are: a classified bibliography of 616 items covering all branches of activities in the U.S.S.R. during the International Geophysical Year ("Bibliographical Index of Literature in Russian Language for 1958." Pp. 63. Moscow: Publ. Acad. Sci. U.S.S.R.); a report on thirteen fulfilled plans of observations, four reports and some articles dealing with geophysical researches carried out with rockets in the United States (Information Bulletin No. 7. Pp. 114. Moscow: Publ. Acad. Sci. U.S.S.R.); a collection of twelve articles dealing with geomagnetism and ionosphere investigations ("Magneto-Ionosphere Disturbances". Pp. 75. Moscow: Publ. Acad. Sci. U.S.S.R.). In each case the text is in Russian; however, there is also a contents in English.

Russian for Scientists

A very slender pamphlet by Prof. J. W. Perry, entitled "Scientific Russian Without Tears", has been issued recently. Unfortunately it is far too short to be of much value to a novice and far too elementary for an advanced student of the Russian language (pp. ii+26. (Reprinted from *The Chemical Bulletin.*) (Chicago: Chicago Section, American Chemical Society, Inc., 1959.) 1 dollar). Its only possible use is as an auxiliary to a normal dictionary in the case of a scientist trying to read Russian scientific literature, but in this case a dictionary of scientific terms would obviously be better. It is "Without Tears" for the simple reason that the majority of words included are international, for example, atom, vector, canal, parameter, etc., and only a knowledge of the Cyrillic alphabet is necessary to read them in Russian. A novice who is struggling with the intricate cases and tenses of the Russian language and cannot ask for a glass of water is invited to read sentences like "rubber similar to isoprene and other unsaturated hydrocarbons takes up bromine". The examples given in this book are mainly from the field of chemistry and physics. Scientists should not content themselves with only picking up a scientific jargon. Unless they know the fundamentals of the language they may misread a scientific article rather than read it. Once they have mastered ordinary Russian, the only additional book they will need is a suitable dictionary.

Films and Film Strips in Teaching

The steady success of the educational films and film-strips produced by Gaumont–British Instructional Films, Ltd., now called Rank Precision Industries, Ltd., was due to clear recognition that they could never be more than aids to learning. The place of the teacher was accepted as paramount and all films and film-strips produced were deliberately designed to support the teacher rather than supplant him. As a result of this policy, Rank Precision Industries, Ltd., is now recognized as a valuable partner by the teaching profession in providing a wide range of both still and moving films. The latest film catalogue describes more than six hundred films in their separate categories with information about their content, running-time, suggested age-group, classification and hire- and purchase-prices. Besides films produced by Gaumont British Instructional, details are given of films produced by Encyclopædia Britannica Films, United World Films, and other organizations. In the film-strip catalogue more than three hundred strips are listed under eighteen subject categories; many of the films are in colour. Both catalogues are attractively produced and can be obtained from the Gaumont-British Film Library, Aintree Road, Perivale, Middlesex.

'Araldite' in Aircraft Research Models

For aerodynamic research, model aircraft of great accuracy and strength are required. A paper, published for the Royal Aircraft Establishment, Bedford, by the Ministry of Supply as Technical Note No. *A.D.W.*6, describes the making of models with shells consisting of 'Araldite' glasscloth laminate. It includes the results of bending tests on 'Araldite' glasscloth panels performed by the Royal Aircraft Establishment, Bedford. These tests show properties of laminates made with various 'Araldite' resins, glasscloth reinforcements and fillers. 'Araldite' epoxy resins, manufactured by Ciba (A.R.L.), Ltd., are extensively used in industry as adhesives, and for casting, laminating, tooling and surface coating. They were chosen by the Royal Aircraft Establishment, Bedford, for model-making because with glasscloth they give laminates with a very high strength/weight ratio. Several models of each type were required and the cold-laminating technique used resulted in these models being identical and of great dimensional accuracy. It is a feature of 'Araldite' epoxy resins that they cure with negligible shrinkage. A description of 'Araldite' and the uses to which it has been put at Bedford has been given by E. J. R. Thomas, of the Wood and Plastics Department (Ciba (A.R.L.), Ltd. Technical Notes No. 206 (February 1960): Model-Making with 'Araldite'. Pp. 12. Duxford: Ciba (A.R.L.), Ltd., 1960).

Measurement of Wind Speeds near a Tornado

An observation has been made of the speed of debris particles whirling round a tornado funnel from enlargements of the separate pictures of a cine film. The maximum value was 212 m.p.h. The observation was made in a tornado which struck Dallas, Texas, on April 2, 1957. On enlargement of the film at the Kansas City Research Unit of the U.S. Weather Bureau it proved possible to identify individual particles of debris whirling round the tornado and compute their tracks and speeds. The observations are reported in the October 1959 issue of the *Monthly Weather Review*.

The Neolithic Revolution

Recently, a British Museum (Natural History) publication entitled "The Neolithic Revolution" has appeared (Pp. vi+60+18 plates. London: British Museum (Natural History), 1959. 5*s*.). The author, Sonia Cole, is well known for her work on certain aspects of African prehistory. The discovery by early man of the possibilities of agriculture and the breeding of animals in captivity produced profound changes not only in his well-being, but also in his outlook on life. This neolithic revolution necessitated communal life, and for the first time man had to live close to his fellow man—not always an easy matter. Food could now be stored and a much larger population could survive. It is not too much to say that we can describe the prehistoric folk prior to these discoveries as our forerunners, those that come after them as our early ancestors. This well-illustrated work discusses such problems as the origins of grain cultivation, the domestication of animals—that is to say, breeding in captivity, not merely taming; flint mining and forest clearance; transport—particularly necessary when a further stage in civilization was reached and the village developed into the town; crafts and buildings.

Fishery Research Training Grants

The Development Commissioners have announced that, in association with the Ministry of Agriculture, Fisheries and Food and the Scottish Home Department, they will award postgraduate training grants in fishery research tenable from October 1. These training grants are intended to enable selected candidates to undergo a specified course of training to fit them for the investigation of problems in marine or freshwater science. Candidates must be British subjects and should be graduates with honours in science of a British university or possess equivalent qualifications. The value of the awards will be £420–£270 per annum depending on where the research training is carried out. Further information can be obtained from the Secretary, Development Commission, 3, Dean's Yard, Westminster, London, S.W.1. Applications should reach the Commissioners on or before May 20.

The British Textile Institute

The Textile Institute celebrates its golden jubilee this year, and in its awareness of the importance of science in the textile industry the theme of the annual conference will be "Fibre Science". The meeting will be held in London during May 30–June 3. The conference will be opened by Sir Harry Melville, who will speak on the impact of modern chemistry on industry in general. Other speakers will include Prof. J. B. Speakman (University of Leeds), Prof.

M. J. Lighthill (Royal Aircraft Establishment, Farnborough), the Rt. Hon. Douglas P. T. Jay, M.P., Prof. D. T. Jack (University of Durham), Prof. W. T. Astbury (University of Leeds), Prof. R. Meredith (Royal College of Science and Technology, Glasgow), Prof. R. Nicholson (Royal College of Art), Prof. Janey Ironside (Royal College of Art) and Sir Walter Puckey (chairman, Automation Consultants and Associates, Ltd., and of Management Selection, Ltd.). Further information can be obtained from the Golden Jubilee Conference Organizer, Textile Institute, 10 Blackfriars Street, Manchester 3.

Advisory Committee on Scientific Work of the Infestation Control Laboratory

THE Minister of Agriculture, Fisheries and Food has appointed the following committee to advise and report annually on the programme of experimental and research work of the Infestation Control Laboratory of the Ministry: Prof. J. B. Cragg, professor of zoology in the University of Durham (*chairman*); Mr. H. R. Hewer, reader in zoology, Imperial College of Science and Technology; Dr. T. Moran, director of research for the Research Association of British Flour Millers, St. Albans, Herts; Mr. F. Rayns, director of the Norfolk Agricultural Station, Sprowston, Norwich; Prof. H. G. Sanders, chief scientific adviser (agriculture), Ministry of Agriculture, Fisheries and Food; Prof. V. C. Wynne-Edwards, professor of natural history, University of Aberdeen. The secretary of the Committee is Miss Y. Larthe. Assessors to the Committee are: Mr. A. S. Fortune, chief inspector, Department of Agriculture for Scotland; Dr. R. A. E. Galley, director of the Tropical Products Institute, Department of Scientific and Industrial Research; Mr. G. V. B. Herford, director of the Pest Infestation Laboratory, Slough, Bucks; Mr. G. G. Samuel, Agricultural Research Council; Dr. E. B. Worthington, deputy director-general (scientific), Nature Conservancy.

Announcements

H.M. THE QUEEN has conferred the Order of Merit on Sir Cyril Hinshelwood, Dr. Lee's professor of chemistry in the University of Oxford and president of the Royal Society. Lord Radnor, chairman of the Forestry Commission since 1952, has been appointed a knight of the Order of the Garter.

DR. RICHARD O. ROBLIN, vice-president for research and development of the American Cyanamid Company, who is known for his work on sulphadiazine and sulphamerazine, has been elected president and director of the Cyanamid European Research Institute in Geneva; Dr. Mario Scalera, assistant to the general manager of the Central Research Division of Cyanamid, has been elected a vice-president of the Institute. The Institute, which last year acquired eight and a half acres of land for its laboratories in Geneva's Cologny section, will be devoted to long-range, basic research in the chemical and related fields.

THE Trustees of the Rockefeller Foundation have authorized a grant of 30,000 dollars to the Marine Biological Association of the United Kingdom for the purchase of research equipment for use in the Plymouth laboratory.

THE Latin American school of physics is to be held this year at the Centro Brasileiro de Pesquisas Físicas, under the auspices of Conselho Nacional de Pesquisas do Brasil, Academia Brasileira de Ciências, Campanha de Aperfeiçoamento de Pessoal de Nível Superior, Pan American Union and Unesco, during June 27–August 7. Further information can be obtained from J. Leite Lopes, Centro Brasileiro de Pesquisas Físicas, Av. Wenceslau Braz, 71 Rio de Janeiro, Brazil.

THE thirtieth annual report of the University Research Committee, University of Birmingham, gives a summary of departmental research progress during the academic year 1958–59. Lists of papers published during the year and of titles of those approved for higher degrees during the period are included in each departmental report, arranged alphabetically by authors (pp. 123. Birmingham: The University, 1960). A selected list of general works and further writings by members of the University staff is appended, arranged under faculties.

THE International Atomic Energy Agency is issuing a world list of institutions concerned with atomic energy (Gen./Pub. No. 3). The list is being issued at irregular intervals as a series of publications; each publication covering a Member State of the Agency. The list is intended to facilitate the exchange of information on nuclear energy between scientists, engineers, research workers and administrators in Member States. Copies can be obtained from the Scientific and Technical Information Division, International Atomic Energy Agency, Kärntner Ring, Vienna.

AN international conference on Powder Metallurgy is to be held at the Hotel Beltmore, New York City, during June 13–15. Further information can be obtained from Mr. Kempton H. Roll, Metal Powder Industries Federation, 60 East 42nd Street, New York 19.

THE sixth Commonwealth Mycological Conference will be held during July 15–22 at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1. Further information can be obtained from the Director, Commonwealth Mycological Institute, Ferry Lane, Kew, Surrey.

THE thirteenth symposium in biology at the Brookhaven National Laboratory on Protein Structure and Function will be held during June 6–8. Further information can be obtained from Dr. D. E. Koshland, jun., Department of Biology, Brookhaven National Laboratory, Upton, L.I., New York.

THE second annual conference of the British Computer Society, Ltd., is being held during July 4–7 at the Sun Pavilion, Harrogate, Yorkshire. Further information can be obtained from Miss D. E. Pilling, Electronic Computing Laboratory, The University, Leeds 2.

THIS year the Charité (Faculty of Medicine), Humboldt University, Berlin, celebrates its 250th anniversary, and functions will be held in conjunction with the 150th anniversary of the University. Further information can be obtained from Dr. Dagobert Müller, secretary of the Committee for Preparations of the 250th anniversary of the Charité, Berlin, N.4, Schumannstrasse 20–21.

ERRATUM. In announcing the award of the J. Lawrence Smith Medal of the U.S. Academy of Sciences to Dr. E. J. Öpik (see *Nature*, April 23, p. 280), it was stated that Dr. Opik is director of the Armagh Observatory; he is, in fact, a research associate of the Observatory, the director of which is Dr. E. M. Lindsay.

THE NATIONAL SCIENCE FOUNDATION, WASHINGTON

As in last year's report, rather more than half the ninth annual report of the (U.S.) National Science Foundation*, covering the year 1959, is occupied by appendixes listing the members of the National Science Board, its staff, committees and advisory panels, the grants for basic research and other purposes, grants for the International Geophysical Year programme, fellowship awards and publications, together with the financial report. About a quarter of the remainder deals with the re-appraisal and re-organization of the status of science in the United States, 1958–59, including a brief account of the two reports, "Strengthening American Science" and "Education for the Age of Science", coming from the President's Science Advisory Committee. This section, and the Chairman's foreword and the Director's statement, are discussed separately (see p. 341 of this issue); the remaining parts of the report, which review the activities of the Foundation itself, are reviewed here.

The significant increase in the support given by the Foundation to basic research in the United States from 25 million dollars in 1958 to almost 65 million dollars in 1959, should be noted first; this includes some 15·5 million dollars for research facilities, of which 12·3 million dollars were in support of facilities in mathematical, physical and engineering sciences. Support in the biological and medical sciences covers a wide range in developmental and environmental biology, systematic and regulatory biology. In genetic biology it is directed towards elucidating the nature of genetic material, the laws governing the transmission of hereditary traits, and the mechanisms controlling and determining the expression of hereditary characters; in metabolic biology, towards the mechanisms of protein synthesis and growth and specific metabolic factors which inhibit growth; in molecular biology, towards the investigation of the structure, synthesis and reactivity of peptides and proteins; and in psycho-biology, to the support of quantitative techniques in physiological and experimental psychology as these develop from mathematics and mathematical statistics.

In mathematical, physical and engineering sciences, a new programme for atmospheric sciences was established, under which the weather modification programme is now handled. Grants in chemistry were chiefly in organic and physical chemistry, while in the Earth sciences, support for oceanography was increased. In the engineering sciences, special reference is made to two grants in plasma dynamics, while the physics programme continued to place major emphasis on high-energy physics, particularly cosmic rays, and increasing attention was given to low-temperature research. Many of the facilities of the National Radio Astronomy Observatory are now approaching completion or actually in operation, and construction of the Kitt Peak National Observatory was started in 1959, where besides a 36-in. and an 84-in. reflector for stellar observations, it is proposed to instal a solar telescope with a parabolic mirror 60 in. in diameter and a focal length of 300 ft.

An Office of Social Sciences was established during the year to support research and related activities in social science disciplines, for which grants during the year totalled 853,000 dollars, including anthropological sciences, sociological sciences, economic sciences and the history and philosophy of science. The Antarctic Research Programme, which received 2·3 million dollars, is supported on a geographical basis and an interdepartmental committee has been set up by the Foundation to examine proposals and programmes of the various agencies and the broad programme suggested by the Committee on Polar Research of the U.S. National Academy of Sciences.

Among the significant research developments of the year to which the report directs attention are the sunspot photographs obtained with the *Stratoscope I* 12-in. balloon-borne solar telescope; the resolution of the galactic nucleus Sagittarius *A* with the new 85-ft. Tatel radio-telescope at Greenbank, West Virginia; the use of a new technique of testing for perception of visual depth to throw light on native and learned factors in the perception of distance; the synthesis of a pituitary hormone of 13 amino-acids linked in a specific sequence resembling adrenocorticotrophic hormone in structure; the identification of a catalytic factor from blood which can transform 1,000–10,000 times its own weight of soluble fibrin into the insoluble form; the discovery of a mollusc thought to be extinct for nearly 300 million years; the establishment of migrations of *Sequoia* from tropical swamps 60 million years ago through adaptation to drier and cooler climates; and the development of a tetrahedral anvil which can generate pressures up to 100,000 atm. at 3,000° C.

During the year the Foundation sponsored and provided partial support for 41 scientific conferences and symposia and awarded 419 grants, totalling 330,000 dollars, to enable scientists to attend international meetings. Fellowship awards totalled 3,937, amounting to about 13·1 million dollars, and with those assisted under the research grants programme, the number of scientists assisted during the year was about 6,000. Of the fellowships, 965 were in the biological and medical sciences, 2,857 in the physical sciences (chemistry, 730; geological sciences, 195; engineering sciences, 558; mathematical sciences, 689; physics, 663), and 59 in the social sciences. Of the total, 1,100 were pre-doctoral, 194 post-doctoral and 83 senior post-doctoral; 302 science faculty fellowships were awarded for improving the quality of science teaching, as well as 628 summer fellowships to secondary school teachers of science and mathematics, 580 summer fellowships for graduate teaching assistants, and 1,050 co-operative graduate fellowships of 2,200 dollars for 12 months. The plans for improving the quality of science teaching by assisting teachers in secondary schools to extend their knowledge of science and of new developments comprise four main programmes on which 33·25 million dollars were expended in 1959. The summer institutes programme provided stipends to

---

* National Science Foundation. Ninth Annual Report for the Fiscal Year ended June 30, 1959. Pp. xvii+274 (12 plates). (Washington, D.C.: Government Printing Office, 1960.) 1 dollar.

20,000 participants. Besides teachers in secondary schools and colleges attending 348 'courses' varying in length from 4 to 12 weeks, 515 teachers and supervisors in elementary schools received training in 12 summer schools; technical school personnel were provided for in two experimental summer programmes and 546 college teachers of science and mathematics attended 20 summer conferences dealing with special fields of science and mathematics. Under the Academic Year Institute programme, providing a year's study in science and mathematics for secondary school teachers, awards were made to 32 colleges and universities, and it is estimated that the 1959–60 programme will support more than 1,500 teachers; while opportunities for further study in out-of-school hours will be provided to about 9,000 secondary school teachers under the In-Service Institutes programme. Special projects in science education on which nearly 9 million dollars was expended cover visits of scientists to secondary schools, the provision of a travelling science library of carefully selected books for high schools, a travelling science demonstration lecture programme for secondary schools and support for summer training of secondary school students. The State Academies of Science, the College Programme and Teacher Improvement Programmes provide for visits by scientists, and foster the participation of undergraduates in research, supplementary training for science teachers and eight special field institutes covering advanced training in highly specialized subjects. On the Course Content Improvement Programme, a further 6 million dollars was expended on projects in elementary and secondary schools and in colleges; this included supplementary teaching aids such as films and television. Activities under the International Science Education Programme initiated during the year include the improvement of science curricula and the training of teachers and also measures to assist science students and scientists to engage in international educational programmes.

The Scientific Man-Power Programme, on which 780,000 dollars was expended in 1959, besides maintaining the National Register of Scientific and Technical Personnel, initiated surveys of scientific and technical employment in private industry and State Governments, of scientific and technical personnel in colleges and universities, and of scientists and engineers in Federal Government employment engaged in research, and pilot studies of the demand for scientists and engineers in several industries. Reports were completed on the knowledge of foreign languages of American scientists in 1954–55, on scientists and engineers in American industry in January 1957, and on employment and other characteristics of American scientific man-power during 1954–55. The measurement and appraisal of the national research and development effort is a major responsibility of the Foundation, and its Office of Special Studies has now completed its surveys of the year 1953–54; its present programme of statistical surveys proposes a detailed survey of each sector every four or five years, summary data only being collected in the intervening years. During the year, a survey was made of expenditure on scientific research and development in the fiscal years 1958, 1959 and 1960, and a survey of scientific research and development expenditure and man-power in colleges and universities during 1957–58 is now being conducted, following the publication of the report on the 1953–54 survey.

During the year, further responsibilities for improving the availability of research information to scientists were assigned to the Foundation by the National Defense Education Act, 1958, and accordingly the Office of Science Information Service and the Federal Advisory Committee on Scientific Information have been established. For the dissemination of scientific information, 146 grants totalling 3·8 million dollars were made for such purposes as documentation research, the international exchange of scientific information, the support of scientific publications and information services and the dissemination of unpublished research information such as unpublished Government research reports. Studies of the flow of information among scientists and of the scientific activity of chemists were completed during the year and five mechanical translation projects are at present supported, as well as the effort of 28 professional societies and academic institutions in providing translations of 35 Russian scientific and technical periodicals and 18 books and monographs. A Foreign Technical Information Centre has been established in the Office of Technical Services of the Department of Commerce, where scientific and technical translations prepared by Government agencies are collected, and their availability is announced. Support of scientific publications covered the issue of *Physical Review Letters*, an experiment in rapid low-cost publication of short, up-to-the-minute articles on physical research, support for the *Journal of Geophysical Research* and a grant to enable *Biological Abstracts* to extend its coverage; while grants in support of information services include one to the Bio-Sciences Information Exchange, administered by the Smithsonian Institution, and continued support to the Office of Critical Tables of the U.S. National Academy of Sciences.

THE PUBLIC AND THE BROADCASTING PROGRAMMES IN BRITAIN

THE British Broadcasting Corporation has issued a report on an inquiry carried out at the end of 1958 by its Audience Research Department*. Its first chapter describes the public and the facilities which are available for listening and viewing, comparing the public which depends solely on sound broadcasting with that which has television as well, and also contrasting viewers who can receive B.B.C. television only, with those who can also receive Independent television. The following three chapters deal successively with listening in the evening, viewing in the evening and listening in the day-time, contrasting the amount of listening or viewing, the selectiveness of listeners or viewers and the distribution of their patronage. A fifth chapter discusses the tastes of listeners and viewers as they emerge when people have a chance to express their views in respect of a range of categories of programme output, and includes a comparison of the tastes of men and women of different age groups and different educational levels. Each chapter ends with a summary of its main findings, but a concluding section of the report entitled "Highlights and Reflections" attempts to view the results as a whole.

---

* British Broadcasting Corporation. The Public and the Programmes: an Audience Research Report on Listeners and Viewers, the time they devote to listening and viewing, the Services they patronize, their Selectiveness and their Tastes. Pp. 71. (London: British Broadcasting Corporation, 1959.) 3*s*. 6*d*.

At the present time there are three distinct publics. The first, 'Band 1/3', which can receive both B.B.C. and Independent television and also sound broadcasting (now about half the population), is gradually swallowing up the other two: 'Band 1', which can receive B.B.C. television and sound (now about 20 per cent), and the 'sound only', which cannot receive television (now about 30 per cent). About 15 per cent had very high frequency receivers, and three-quarters of these are in television homes. The 'sound only' public is somewhat older and of a slightly higher educational level than the 'sound and television' public, and on average families in this group are a good deal smaller than 'sound and television' families. The 'Band 1' public also was somewhat older and of a rather higher educational standard than the 'Band 1/3' public.

The typical viewer watches television in winter for approaching two hours each evening, and this means that at peak hours not far short of half the adult population is watching television. The typical listener has his radio on for not much more than half an hour a night and will usually be doing something else at the same time. In television homes sound broadcasting is used very little in the evening, and after 6 p.m. it is catering primarily for people who have no television set. The vast majority of its day-time audiences, particularly in the early morning period and on Sundays, consists of people who have television sets. The inquiry showed that most people exercised their opportunity to choose between different programme services; those who did so, both viewers and listeners, outnumbering single-service loyalists by about two to one; but those who settled for one service were by no means homogeneous in either choice or tastes. There was an abnormally high proportion of discriminating listeners among those who limit their listening to the Home Service, and an abnormally high proportion of discriminating viewers among those who, though they could view Independent television, rarely did so.

A relation was noted between the amount of time people devote to listening or viewing and the services they patronize. The more time a person spends in listening the greater the proportion of that time he is likely to give to the Light Programme; similarly, the more he views, the greater is likely to be the proportion of his time spent in viewing Independent television. The inquiry showed that the less a person listens or views the more likely he is to be selective, and the more selective he is, the more likely he is to prefer the kinds of programme characteristic of the Home Service and the B.B.C. television than of the Light Programme and Independent television. Again, the older a listener is, the less likely he is to enjoy feature films, crime series, or westerns. Sex is sometimes predictive, women being more likely than men to be 'heavy' consumers of both sound and television in the evening. Science features on television, ranging sixteenth out of eighteen categories in popularity with the public, were not unpopular with men but were unpopular with women and most unpopular with viewers over sixty. Their popularity increases with each step up the educational level, and most often the individual's behaviour, attitudes and tastes tend to be associated with the age when his full-time education ceased, and/or 'occupational status', frequently reinforced by information about the newspapers he reads. Again and again the report demonstrates that the higher the individual's cultural level, the less he tends to listen or view, the more likely he is to be selective and to take an interest in serious types of programmes. Whatever measure of 'cultural level' is used, the population appears as a sharply tapering pyramid, and, accordingly, the more a type of broadcasting output or service depends for its custom upon people who have enjoyed cultural advantages or want something more than the undemanding relaxation, the more numerically restricted its audience is likely to be. So far as science is concerned the inquiry indicates that nearly all effective viewing is on B.B.C. television and hence anything that prejudices B.B.C. television as against Independent television would be liable to prejudice the use of television in the presentation of science to the public.

AUTOMATION AND ITS HUMAN REPERCUSSIONS

THE mental health problems of automation were examined recently by a World Health Organization study group (Study Group on the Mental Health Problems of Automation. (World Health Organization Report, Series No. 183.) Pp. 30. Geneva: W.H.O.; London: H.M. Stationery Office, 1959). It is not automation in the form of automatic co-ordination of machine tools on production lines, nor in the form of automatic control over manufacturing processes, that is liable to bring about the most revolutionary changes in mechanized work, but the rapid and automatic processing of an increasing range of technical and business information by the electronic digital computer.

Emotional reactions to automation range from unreasonable hopes of a rapid rise in living standards to fears of upheavals in conditions of employment and of difficulty in adaptation to the new machines. These reactions are of an anticipatory nature and are not based on actual experience. In the meantime, workers in automated undertakings are already suffering from physiological and psychological strain.

Because of its nature, automated work may have psychological consequences: for example, if the manual activity of a worker who has been accustomed to assess his work on the basis of his physical effort is reduced, he will feel himself less useful and suffer from a sense of inadequacy; if contact with the machine or with the object on which he is working is eliminated or reduced, he will see his task in a more abstract form and this may lead to anxiety; if his responsibility is increased his job may become more of a strain.

What kind of strains are imposed upon the worker ? First, there is the nervous strain caused by the need of unremitting attention to signals of varying perceptability, often separated by long intervals. The less the physical activity of such a worker and the greater the number of indicators to be watched, the more the nervous tension to which he will be exposed. In these circumstances particular importance will be attached to working conditions, such as temperature, sound-proofing, lighting, and the position of the operator and the machines. By preventing the operator from communicating with others, automated work tends to isolate him both physically and mentally. This feeling of isolation may be heightened by the background noise made by the machines.

In addition to its direct effects upon the workers' mental health, automation will undoubtedly have indirect social consequences. Families may, for example, be affected by the increased mobility of labour. The most serious difficulties indirectly affecting mental health are, however, liable to arise in connexion with the organization of the work itself. If automation calls for more shift work (as appears likely), this will certainly be opposed by the workers and their families.

Automation may provide certain satisfactions ; for example, in an entirely automated plant, each operator becomes more or less his own master ; the gap lessens between the factory worker and the office worker, and changes of occupation in middle age should be easier.

Efforts to mitigate the harmful effects of automation on mental health should be based on information and education. Education will be all the more effective if it is directed primarily towards those in key positions, that is to say, managers, engineers, trade-union leaders and the medical profession, particularly works doctors.

EMPLOYMENT OF WOMEN IN BRITAIN

THE Institute of Personnel Management has published under the title "Working Wives" a survey of facts and opinions concerning the gainful employment of married women in Britain carried out in co-operation with Mass Observation, Ltd., by Viola Klein during the autumn months of 1957, when out of 12,820,000 married women in Great Britain nearly 4 million were gainfully employed (Occasional Papers, No. 15. Pp. 63. London: Institute of Personnel Management, 1960. 7*s.* 6*d.*). Thus, in about one out of every three households the wife contributes by her earnings to the family income, but the apparent steep rise in the employment of married women since 1951 is due to the Population Census seriously underrating the number of married women in employment, particularly part-time. The outstanding impression gained by the survey is that women's lives to-day are dominated as much as ever by their role—actual or expected—as wives and mothers, and all other occupations are subordinated to their responsibility for home and family. The growth in the number of married women going out to work is due to the smaller size of their families and the general reduction in housework through the modernization of household techniques, combined with a striving to improve their standards of living. It is not widely assumed that married women should have jobs, although among the more highly educated single women in the sample nearly one third wished to continue their careers after marriage ; this is nearly double the percentage in the next occupational group of women willing to continue in employment not merely temporary. The taking up of employment by married women appears to result from unforeseen though not unforeseeable circumstances, and men appear to be less conservative in their outlook in these matters than they are usually assumed to be.

Slightly more than one half the married women in employment have part-time jobs, which may be in the region of 4–30 hr. per week. The sample also showed that two-thirds of the women in part-time employment are engaged in unskilled or semi-skilled work, and that shorthand typing is the occupation least likely to offer any scope for the married woman who wishes to supplement her income by part-time employment. In some smaller occupational groups, such as teachers, nurses, social workers, a shortage of trained staff has opened the doors to part-time employees, and though the problems involved have not yet received the attention they deserve, more opportunities may well be offered here in the future for married women to combine a career with having a family. Women, in fact, it is concluded, are an essential and distinctive part of our man-power resources.

EXPLORATIONS OF THE GALÁPAGOS ISLANDS

THE Galápagos Islands have recently attracted widespread attention as a result of the Darwin centenary and the measures at present being taken to preserve and study their flora and fauna. The Galápagos Islands have been one of the principal fields of endeavour of the California Academy of Sciences since its first expedition there during 1905–6, and its collections from the archipelago are unsurpassed. It is therefore appropriate that the Academy should publish a short history of the islands by the late Joseph Richard Slevin, for more than fifty-three years associated with its Department of Herpetology, and a member of the original expedition, who for half a century maintained an active interest in the islands and published a number of scientific and popular papers about them (Occasional Papers of the California Academy of Sciences. No. 25: The Galápagos Islands : a History of their Exploration. By Joseph Richard Slevin. Pp. x+150. San Francisco : California Academy of Sciences, 1959).

This publication gives a description of the islands, their geology, climate, and fauna, but it is mainly concerned with their history. An immense amount of literary research has gone into it, and the author has ransacked the archives of America and Europe to bring together the information that he has skilfully welded into a fascinating account of the islands from their discovery to the present day. He has consulted the original log-books of the early explorers, official reports from naval officers of many nationalities engaged on surveying, and the letters and logs of whalers and tortoise-oil hunters. There can be few records of visits to the islands that he has not seen, and his illustrations range from reproductions of Cowley's drawings made in 1684 to photographs of many interesting nineteenth-century ships that worked there, and of living giant tortoises and of the devastation of broken carapaces left by the oil hunters. The paper concludes with a notice of all the scientific expeditions that have been at the Galápagos, sections on the giant tortoises and the preservation of the fauna, and a select bibliography. Slevin could have wished for no better monument.

L. HARRISON MATTHEWS

THE AUSTRALIAN DEFENCE STANDARDS LABORATORIES

THE annual report of the Defence Standards Laboratories of the Department of Supply, Australian Defence Scientific Service, for the year ended June 30 1959, the staff of which numbered 621 at the end of the year, compared with 637 at July 1, 1958, includes lists of senior and professional staff, papers published, and committees on which the Laboratories' staff have served*. The Laboratories, besides providing a scientific advisory service to those concerned with development, manufacture, inspecting, procurement, storage and use of defence material, have a recognized function of research, both in relation to their scientific advisory function and in advising and assisting the defence services on the development of new and improved materials, methods and equipment. The range of the Laboratories' activities may be illustrated by mentioning a few of the investigations on which some notes are given in the report.

In chemistry these include studies of the pore structure and other physical characteristics of brown coal and copra charcoals, the oxidation of phosphorus in the decomposition of cast iron by acid, determination of minute amounts of ammonia by Nessler's reagent and of small amounts of tin, and of the dyeing of textiles. In metallurgy the study of chromium and chromium base high-temperature alloys continued, as well as of the production of pure chromium, the processing, properties and structure of chromium and chromium alloys and also on titanium alloys. In physics, further experience was gained in the technique of electron spin resonance, the use of X-ray diffraction in studying the structural changes in the ageing of titanium–chromium alloys, and on the stabilization of a.c.-line voltages. A stable electric arc was developed, and further work carried out on precise load measurement and the determination of gamma-ray source strengths. Miscellaneous work included improvements in electrophotography such as improved particulate photoconductor coatings of acceptance to charge on the surface, uniformity, sensitivity and spectral response, and the study of thin selenium films for xerography.

HETEROGENEITY OF LECITHINS LABELLED WITH PHOSPHORUS-32

By DR. F. D. COLLINS
Biochemistry Department, University of Melbourne

SINCE the first use of phosphorus-32 in 1937 [1] for the study of phospholipid metabolism an immense amount of work has been done using this isotope; but in every case the results have been limited by the analytical methods used to separate the very complicated mixture of naturally occurring phospholipids. In the early work, for example, lecithin was isolated as the ethanol-soluble material, but this was far from pure. In more recent years the use of chromatography on alumina[2,3] or silicic acid[3] has yielded lecithins which analysed correctly in that the molar ratio of phosphorus : choline : fatty acid plus fatty aldehyde was equal to 1 : 1 : 2. In addition mild alkaline hydrolysis[4,5] of lecithin has been shown to yield glyceryl–phosphoryl–choline, which could be isolated and purified by paper chromatography. The use of these procedures enabled the mean specific radioactivity to be determined but took no account of the possible effects of the different fatty acids and fatty aldehydes that were present. Because of the absence of methods for fractionating the lecithins it has had to be assumed that any variation between lecithins was not large enough to invalidate comparisons of the specific radioactivities between the lecithins and other phospholipids. The following experiment shows that quite large variations in specific radioactivity can exist between different lecithins.

A rat (310 gm.) was injected intravenously with 0·8 mc. of labelled sodium dihydrogen phosphate in 0·1 *M* sodium chloride and 0·001 *M* sodium dihydrogen phosphate and killed after 90 min. The liver lipids were extracted, dinitrophenylated and methylated as described by me[6], and then divided at −18° into an acetone-soluble and an -insoluble fraction. The acetone-insoluble materials were free of dinitrophenyl-containing lipids, and countercurrent distribution (120 transfers) in carbon tetrachloride–chloroform–methylene chloride–methanol–

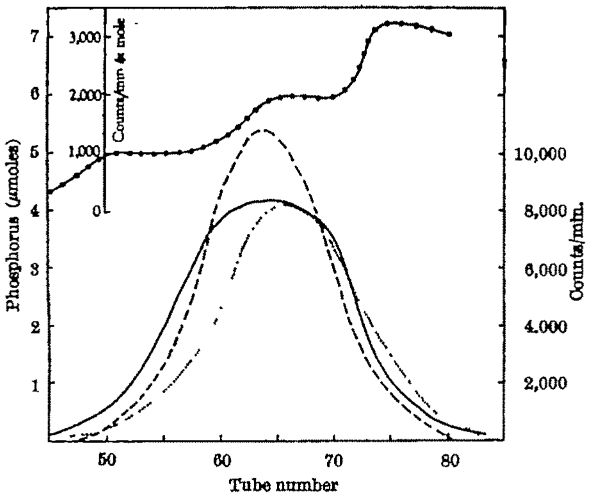

Fig. 1. Counter-current distribution of lecithin in carbon tetrachloride–methanol–water. —, phosphorus (μmoles); . . ., counts/min.; – – –, theoretical curve (phosphorus μmoles); · – · – ·, specific radioactivity counts/min./μmole

water (25 : 15 : 10 : 40 : 10 by volume) showed that lecithin (partition coefficient = 0·20) constituted 81 per cent of this fraction. The contents of the tubes containing the lecithin (mean specific radioactivity 1,750 counts/min./μmole) were combined and redistributed (120 transfers) in carbon tetrachloride–methanol–water (62 : 35 : 3·15 by volume) and the distribution obtained is shown in Fig. 1.

The theoretical distribution of 76 μmoles of a pure material with a partition coefficient of 1·15 is shown, and it will be seen that the experimental curve is broader and lower than that which would be expected for a pure compound. The curve for the radioactivity is skew, and the plot of the specific radioactivity shows a stepwise curve increasing in the more polar direction; the mean specific radioactivity is 1,690 counts/min./μmole but varied between 600 and 3,250 counts/min./μmole.

The lecithins were divided into three fractions obtained by combining the contents of the tubes as shown in Table 1. Each fraction was submitted to mild alkaline hydrolysis[4,5] and the water-soluble products subjected to paper chromatography in phenol–water (saturated). In each case a phosphate spot was detected[7] with an R_F of 0·90–0·95 which corresponded to glyceryl–phosphoryl–choline. The spot was cut out, extracted with water and the specific radioactivity of the phosphorus determined. The ether-soluble material remaining after the mild alkaline hydrolysis was further hydrolysed by heating with N potassium hydroxide in ethanol for 1 hr. The unsaponifiable material was extracted with diethyl ether from the alkaline digest and discarded. The mixture was then acidified and the fatty acids extracted with diethyl ether. The uptake of hydrogen of the fatty acids in the presence of a platinum catalyst was measured as an indication of the degree of unsaturation with the results shown in Table 1.

Table 1. COUNTER-CURRENT DISTRIBUTION OF LECITHIN

After distribution in carbon tetrachloride–methanol–water the contents of the tubes shown below were combined and analysed

Fraction	*A*	*B*	*C*
Tube Nos.	44–59	60–70	71–83
Phosphorus (μmoles)	21·4	40·0	13·1
Specific radioactivity (counts/min./μmole phosphorus)			
Calculated from graph	1,000	1,750	2,520
From isolated glyceryl-phosphoryl-choline	985	1,930	2,750
Absorption of hydrogen (ml. at S.T.P.) per 100 mgm. fatty acids	6·89	9·14	Insufficient for analysis
Apparent 'partition coefficient'	0·85	1·22	1·73

There was close agreement between the specific radioactivity measured on the intact lecithin and the isolated glyceryl–phosphoryl–choline. Fraction *B* was more unsaturated than *A* but unfortunately there was insufficient material for the examination of fraction *C*. Synthetic dimyristoyl lecithin had a partition coefficient of 0·9 in carbon tetrachloride–methanol–water while the mid-points of fractions *A*, *B* and *C* correspond with partition coefficients of 0·85, 1·22 and 1·73 respectively. These results indicate that the saturated fatty acids predominate on the non-polar side of the distribution and the unsaturated ones on the more polar portion. Thus one can conclude that lecithins containing the more unsaturated fatty acids exchange more rapidly with inorganic-phosphate.

A preparation of a mixture of phosphatidyl ethanolamine and phosphatidyl serine (after dinitrophenylation and methylation) from the same animal as that used for the lecithin referred to above showed a similar skew distribution of radioactivity both in carbon tetrachloride–methanol–water (62 : 35 : 3·15 by volume) and in petroleum ether (b.p. 110–120°) : methanol. The specific radioactivity ranged from 10,600 to 16,500 counts/min./μmole phosphorus with the highest values on the more polar side of the distribution. The fatty acids were not examined and in this instance there was about 80 per cent phosphatidyl ethanolamine and 20 per cent phosphatidyl serine, but previous work had shown that there is little or no separation of these two phospholipids in the solvent system used. In spite of these limitations it is very likely that this skew distribution is also due to the partial segregation of phospholipids with differing fatty acid compositions.

The two examples given here show a range of specific radioactivity but their means still differ significantly. However, in other cases the results may not be so clear cut and some of the conclusions reached by the use of radiophosphorus may have to be revised. It will be necessary to fractionate each phospholipid in order to study the correlation between fatty acid composition and the turnover of the lipid-phosphorus.

Chromatography on silicic acid can be used[8] but counter-current distribution of the purified phospholipids provides a means in which the separations can be precisely controlled.

I am indebted to Dr. K. W. Zimmermann, Commonwealth Scientific and Industrial Research Organization, Melbourne, for the determination of hydrogen uptake of the fatty acids.

MECHANISM OF THE GASTRIC SECRETION OF HYDROGEN IONS

By PROF. SPYRIDON G. A. ALIVISATOS

Mount Sinai Medical Research Foundation and Hospital, Chicago Medical School

THE experimental work and theories proposed for the formation of hydrochloric acid in the stomach were reviewed by Heinz and Öbrink[1]. Secretion of gastric acid appears to be dependent on aerobic metabolic processes; but glycolysis may also contribute to a small extent. The probable participation of various enzyme systems in the acid-producing mechanism was also discussed[1]. Such systems would eventually couple with the above-mentioned energy-yielding processes. Of the two ionic species involved, both the hydrogen and the chloride ions seem to be actively secreted, but the latter cannot be responsible for the essential part of acid formation[1,2]. Recently, Heinz and Durbin[3] accumulated more evidence for the existence of an independent 'hydrogen ion pump' in the stomach mucosa. However, at present there is no enzyme system that could be identified with any degree of certainty with this 'pump'.

The stimulating effect of histamine on the gastric secretion was first discovered by Popielski[4]. This effect is independent of the nervous system and, most probably, is due to a direct action of the drug upon the parietal cells of the gastric mucosa[5]. A steady concentration of histamine should be maintained in the body in order to achieve a steady state of elevated secretion of acid in the stomach (references in ref. 1).

Diphosphopyridine nucleotide (coenzyme I), which is an 'onium'-bearing compound, may undergo in the presence of a suitable enzyme[6] either hydrolysis or imidazolysis of its nicotinamide–ribose bond[7]. Both these processes are accompanied by the liberation of a hydrogen ion. The latter is, in a sense, forcibly ejected during the reaction, since both enzymic processes, namely, hydrolysis and imidazolysis, occur at neutrality, while protonation of either nicotinamide or the imidazolytic products of coenzyme I (for example, the histamine dinucleotide[8]) occurs at much lower *p*H values (for a thermodynamic evaluation of this question see ref. 9).

S-adenosyl-methionine, a sulphonium-bearing compound, may also undergo imidazolysis, as inferred from the *in vivo* work of Schayer *et al.* (references in ref. 10), a preliminary report of Brown *et al.*[11] and our unpublished studies (S. G. A. Alivisatos *et al.*, in preparation).

The above-mentioned observations led recently to the hypothesis that the immediate mechanism for hydrogen ion production in the stomach mucosa may involve the degradation of an 'onium' structure similar to that present in coenzyme I or in S-adenosylmethionine. Hydrolysis or, alternatively, histaminolysis (imidazolysis) of this structure would yield the necessary hydrogen ions (Fig. 1). In view of the relatively large quantities of hydrogen ions secreted in the stomach, these processes should be reversible, provided that the required energy from aerobic or glycolytic metabolic sources would be available. Overall reversibility, however, would undoubtedly involve different routes. In general, restoration of the 'onium' structure would probably proceed through phosphorolytic pathways involving nucleoside triphosphates (Fig. 1). In addition, while direct reversibility in hydrolysis would be very unlikely, imidazolysis could possibly be to a limited extent reversible, depending on the *p*K′ value for the protonation of the imidazolytic product and on the *p*H range of activity of the enzyme(s). Such 'direct' reversibility could, perhaps, explain anomalies of 'back-diffusion' of hydrogen ions observed in histamine-stimulated stomach pouches (references in ref. 1).

According to this hypothesis, the stimulatory effect of histamine in gastric secretion would be due to its higher affinity, as compared to the affinity of water, for the enzyme-substrate intermediate. This would be in accord with the observation that, at neutrality, histaminolysis of coenzyme I predominates and proceeds to quantitative yields when the ratio of this imidazole to water is about one to 50 (ref. 12). By analogy with the intracellular distribution of the diphosphopyridine nucleotidase of rabbit erythrocytes[13], the enzyme(s) catalysing the reaction(s) postulated above may reside in the mucosal (secretory) side of the membrane of those cells of the stomach mucosa that are responsible for the hydrogen ion secretion (probably the parietal cells; however, see ref. 1).

The previously mentioned necessity of a steady histamine concentration in the body fluids as a prerequisite for a steady elevation of the hydrochloric acid secretion-rate in the stomach[1] pointed towards a perhaps small but continuous 'leak' of the hypothetical imidazolytic product. Accordingly, my first experimental approach was a trial to study the fate of histamine in the isolated stomach. It was hoped that this might lead to conclusions with respect to the nature of the postulated 'onium'-bearing structure. For this purpose, stomachs of white mice were excised and washed as described by Davenport *et al.*[14]. A glucose-containing Krebs–Henseleit type saline also described by Davenport[15] was used, after gassing with oxygen, for the washings and as an incubation medium. The washed stomachs were filled with this saline ('stomach contents', approximately 0·7 ml. per stomach) and both cardiac and pyloric ends were tied with silk thread. The liquid-inflated stomachs were then incubated at 37° C. with shaking, immersed in saline[15] ('nutrient medium', approximately 8·0 ml. per stomach). Throughout the incubation period of 60–90 min., a continuous stream of oxygen was bubbled through the 'nutrient medium'. In preliminary experiments it was found that under these conditions mice stomachs would produce about 3·7 μequiv. of acid per ml. per hr. When 2(ring) carbon-14-labelled histamine was included in the 'stomach contents' (4·0 μmoles per ml.; 4·75 curies per mole) acid production rose over that of the control (hista-

		(*a*) Material soluble in water : ethanol : ether (1 : 1 : 25)			(*b*) Material insoluble in water : ethanol : ether (1 : 1 : 25)
		1. Water	2. Ether	3. Insoluble	1. 0·2 *N* HCl fraction*
1. Stomachs, mouse	5·7	76·0	1·0	4·0	14·0
2. Stomachs, mouse	6·3	82·2	0·2	0·1	10·9
3. Stomachs, mouse	44·0	34·7	2·0	0·4	18·7
4. Stomachs, frog	45·0	44·5	0·2	0·1	10·2
5. Intestines, mouse	67·5	14·1	9·1	0·1	8·0
6. Intestines, frog	35·3	16·6	2·7	0·8	44·3

Each experiment comprised 4–5 stomachs or intestines. The figures represent per cent counts per min. of those originally added. Total radioactivity recovered in each experiment was about 95 per cent (mean value).

* The insoluble residue that could not be extracted with water (Fraction IIb_2) was not tested for radioactivity.

mine omitted) by about 30–50 per cent. Mouse intestinal fragments (ileum) were excised, washed and utilized in a similar manner. In experiments with frogs (*Rana pipiens* and *Bufo bufo bufo*) the saline[15] was diluted with water to 2/3 and incubations were carried out at room temperature. Frog stomachs (only the mucosal layers) were prepared as described by Davies[16]. Frog intestinal fragments (muscularis included) were prepared as above. At the end of the incubation, the 'nutrient medium' was acidified with 0·1 *N* hydrochloric acid to *p*H 2·0, while the liquid-inflated stomach (or intestine) was dropped in a mortar containing a dry-ice ether mixture. Three minutes later the ether was removed by decantation and kept aside, while the solid-frozen organ was pulverized with a pestle. A volume of ethanol equal to the volume of the 'contents' was then added to the moist powder and mixed. Afterwards, the previously used ether was recombined slowly under continuous stirring and the mixture was centrifuged at 1·5 × $10^3 g$ for 15 min., in the cold. The supernatant (water : alcohol : ether = 1 : 1 : 25) was evaporated to dryness under reduced pressure and the residue was extracted as indicated in Table 1 (*a*). The precipitate of this centrifugation (Table 1 (*b*)) was further extracted with 0·2 *N* hydrochloric acid. Attempts to solubilize the remaining residue by more drastic means have been, up to now, unsuccessful. Table 1 indicates the percentage radioactivity present in the various fractions. Evidently a considerable portion (5–6 per cent) of the total radioactive material penetrated through the stomach walls from the 'contents' towards the 'nutrient medium' (Nos. 1 and 2, Table 1). This material differed considerably in its migratory properties from histamine (1, Table 2). In experiments with frog stomachs (mucosal layer) and intestinal fragments (mouse or frog) increased physical porosity of the wall, often identifiable during the washings, contributed to the passage of larger quantities of unaltered histamine. This was also the case in a few experiments with mouse stomachs (Nos. 3–6, Table 1).

The various fractions of Table 1 were separately condensed to a small volume and used in paper chromatographic[12,17–19] and paper ionographic[6,9,12] studies. Results from an experiment with mouse stomachs are summarized in Table 2. They are expressed in terms of relative movements with respect to histamine. The migratory properties of a few imidazole derivatives are also included in Table 2. In general, during incubation with the stomach, a number of histamine derivatives were formed. In some instances as many as five distinct radioactive peaks could thus be registered (IIa_1, System *B*, Table 2). Although some of these peaks could represent artefacts formed during the fractionation procedures, notable differences observed between the products formed in the stomach and those in the intestine (not included in Table 2) strongly support the view that most of those peaks correspond to *bona fide* catabolic changes of the histamine molecule. Unchanged histamine was also present in most of the fractions, often representing the major peak (Table 2).

Ionographic studies at *p*H values ranging from 3·0 to 9·0 showed that cationic groups were predominant in almost every derivative. Many of these substances were devoid of any anionic group. How-

* *A*, *n*-propanol/0·05 *M* acetic acid, 60/40 (ref. 12); *B*, *n*-butanol/ethanol/conc. ammonia, 80/10/30 (ref. 17); *C*, *iso*propanol/pyridine/water, 2/2/1 (ref. 18); *D*, pyridine/water, 65/35 (ref. 19). All proportions are volume per volume. Movements of the various substances were divided by the movement of histamine in the corresponding system, and the ratios (relative movements) are given in the table. These relative movements may be converted to R_F values by multiplying by the R_F values of histamine given above.

† Ionographic movements are expressed relative to the movement of histamine, the migration of which towards the negative pole was always taken as unity.

‡ Italic figures represent the major radioactive peak (up to 70 per cent of the total counts present in the fraction).

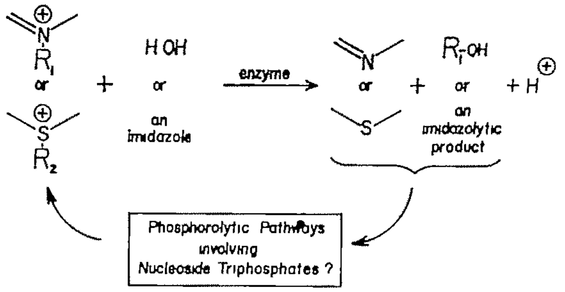

Fig. 1. Proposed mechanism of hydrogen ion production in the stomach mucosa. The postulated 'onium' structure could be an integral part of either a relatively small molecule or a large entity, possibly a lipoprotein embedded in the mosaic of the cell membrane (mucosal or secretory end). A similar intracellular distribution could also apply for the enzyme

ever, in a few instances anionic groups were present; but at most pH values they were effectively balanced or overpowered by the cationic groups present in the molecule. A limited number of ionographic experiments at high pH values (pH 11·5–12·5) indicated that N(ring)-substituted histamine derivatives might be included among these substances. Only results from experiments at pH 3·5 have been included as an example in Table 2. Further identifications based on migratory properties and certain colour reactions (diazo reaction, ninhydrin, etc.) would only be tentative at this stage and are deferred until isolation of each of these products, now in progress in this laboratory.

In conclusion, the experimental approach outlined above, namely incubation of isotopically labelled histamine in isolated stomachs and intestines of mice and frogs, led to the preliminary separation of a few derivatives of histamine. Isolation and identification of these derivatives are now in progress. It is hoped that this might lead to recognition of the moiety (R_1 or R_2 of Fig 1) of the postulated substrate implicated in the hydrogen ion secretion. However, it should be emphasized that even after positive identification of this imidazolytic product, the exact nature of the parent compound bearing the 'onium' structure (Fig. 1) would still remain uncertain. Different approaches now considered in this laboratory would be required to clarify this problem.

I wish to thank my associate, Mrs. F. Ungar, as well as Messrs. D. Cohen and L. Lukacs, for their invaluable assistance in the performance of these experiments. This investigation was partly supported by Grant No. *E*-2436 from the U.S. National Institutes of Health, Grant No. *G*-7644 from the National Science Foundation, Washington, D.C., and Grant No. *P*-241 of the American Cancer Society, Inc.

SIGNIFICANCE OF THE 'EQUIVALENT REDOX POTENTIAL' IN AQUEOUS SOLUTIONS UNDER IONIZING RADIATION

By Dr. G. H. CARTLEDGE
Chemistry Division, Oak Ridge National Laboratory, Tennessee

IN a recent paper[1], Henderson, Lovering, Haines and Casey presented results which support the view of Dainton and Collinson[2] that an aqueous system exposed to ionizing radiation has a unique 'equivalent redox potential' which is characteristic of the solvent. This concept arose from Allen's prior discussion of the fate of an added oxidation-reduction couple under irradiation[3]. The concept was criticized by Veselovsky[4], who pointed out briefly that it neglects consideration of the kinetic factors involved. Reference made to work done by Clark in Oak Ridge National Laboratory[5,6] indicates that the kinetic factors still have not been adequately appreciated, though the experimental results of Henderson *et al.* appear to be entirely valid and constitute an excellent confirmation of the general idea.

To discuss the equivalent redox potential requires careful discrimination as to the nature of the potential under consideration. The radiolytic radicals, for example, H and OH, are not in equilibrium with water, but are present at concentrations dependent upon the intensity of irradiation and the rates of their disappearance by various processes. If one knew the standard free energies of H and OH and their concentrations in the irradiated solution, one could calculate the e.m.f. of a cell corresponding to the overall reaction $H + OH \rightarrow H_2O$. Such an e.m.f. could be measured only if it were physically possible to have two electrodes, each acting reversibly with respect to one of the half-reactions alone. This e.m.f. would bear no relation to a single potential such as the equivalent redox potential is considered to be, however. To refer to a real and presumably measurable half-cell potential characteristic of the aqueous medium under irradiation presupposes the insertion of an inert conducting material for the measurement of the potential. When this is done, however, the potential measured between the electrode and a reference electrode is a steady-state mixed potential, the value of which depends upon the kinetics of all processes, anodic and cathodic, occurring at the interphase between metal and solution[7]. The observed potential will depend upon electrode reactions by which the system is attempting to approach a state of chemical equilibrium while radicals are being continuously produced, and the rates of these processes are determined by kinetic parameters. Posey[8] has given a mathematical treatment of similar situations, which would be applicable here if the electrode processes were under activation control and the requisite data were available.

The measurable, although irreversible, value of an electrode potential in an irradiated solution thus includes anything that affects the polarization of the electrode, such as the activation energies of the individual processes, which, in turn, depend in different ways upon the composition of the electrode and its surface state. Such effects were shown clearly by the experiments in this Laboratory and also in those cited by Veselovsky. The potential is affected also by the passage of different gases through the solution, or by addition of materials which react rapidly with one or the other of the active radicals produced by radiolysis. Initial reaction-rates are chiefly interesting to radiation chemists in connexion with the determination of G values. These are necessarily complicated, however, by the fact that the radiolytic products may act both as oxidizing agents and as reducing agents in individual cases, and that the oxidation-reduction reactions may proceed through unstable intermediates. There are numerous competing processes, therefore, and an electrochemical treatment is scarcely possible, though transient potentials are conceivable which would still be determined by the particular mechanisms in operation and by the condition that the sum of all anodic currents at the electrode must equal the sum of all cathodic currents on open circuit. The kinetics of such processes has been determined in certain cases[9]. The discussion which follows applies only to steady states.

We may consider, first, the case in which the solution contains no redox system other than radiolytic radicals themselves and their reaction products, at concentrations which may depend upon the type as well as the intensity of radiation. At an electrode, these reactants enter into electrode reactions in the futile attempt to approach equilibrium, the direction of change in each reaction being in accordance with the appropriate free energies. The electrode then takes a potential that is fixed uniquely by the kinetics of all cathodic and anodic processes occurring on it. Clark's measurements were made in a solution containing no redox couple foreign to the water and acid, other than trace impurities. With a platinized electrode in 0·10 N sulphuric acid at 85° under gamma radiation and exposed to air, the stable potential was found to be approximately 0·90 V. noble to a reversible hydrogen electrode in the same solution. The potential was shown to be quite different, however, when the solution was swept by hydrogen or nitrogen, or when smooth platinum or stainless steel replaced the platinized electrode. In these measurements, the potential was determined by electrode reactions of radiolytic products alone, and the value shifted rapidly upon application or removal of the gamma source.

If, now, a redox system is added to the solution after the steady-state potential appropriate to radiolytic products alone has been established, additional electrode processes become possible. Assume first that reactions of the added substances with radiolytic products occur only heterogeneously as electrode processes at the surface of the electrode. Depending upon the value of the normal potential of the redox couple, the activity of its components in the solution and various kinetic parameters, these reactions will polarize the electrode either cathodically or anodically, the relative activities of the oxidized and reduced species changing correspondingly. Since radiolytic products are being formed continuously, however, no steady-state potential can be attained until net oxidation or reduction of the added components proceeds to the point that their potential at the same electrode equals the potential of the radiolytic products alone under the prevailing experimental conditions. (This assumes that the processes at the electrode are kinetically independent.) Hence the observed potential should be independent of the system added, so long as a true steady state is reached. Unless the E^0 value of the oxidation-reduction couple is within a few tenths of a volt of the potential indicated by the platinized (reversible) electrode, however, one or the other of its components must necessarily be converted essentially completely into the other, as observed. If the reactions occurred only at the electrode, however, the fate of the redox couple would depend upon the polarization characteristics of the electrode used.

The situation is not greatly different if it is assumed, more realistically, that the reactions between added components and radiolytic products proceed chiefly and rapidly in the homogeneous aqueous phase. Again, the steady state to be reached involves production and consumption of radiolytic products at equal rates. The oxidation-reduction reactants then adjust themselves to such activities that this condition is satisfied. In other words, the relative activities of the added oxidation-reduction components in the steady state have become such that their reactions no longer disturb the steady-state concentrations of radiolytic products attained in the absence of these components. A suitable indicator electrode inserted in the solution will now give the corresponding redox potential, which the results of Henderson *et al.* show to be essentially independent of the identity of the system used. That a platinized electrode in Clark's experiments without added oxidation-reduction components indicated nearly the same potential as observed by Henderson *et al.* at a lower temperature shows merely that this type of electrode indicates reliably the kinetics of the radical reactions in the homogeneous phase, which is not true for stainless steel or silver, for example.

The behaviour of the potential upon cessation of irradiation is also understandable. In Clark's experiments, no added oxidation-reduction system was present other than trace impurities; hence the potentials shifted rapidly when irradiation ceased. The shift was in the direction determined by the transient condition then prevailing at the active interphase. In the experiments of Henderson *et al.* cessation of irradiation left an oxidation-reduction system in solution in electrochemical equilibrium, with concentrations much larger than those of the radiolytic products by which the steady-state potential was determined in their absence. The potential therefore shifted only slowly from the reversible potential of the couple at the existing activities, doubtless owing to reactions of residual radiolytic products of long life, such as hydrogen peroxide.

Dainton and Collinson discussed the numerical value of the equivalent redox potential in terms of reversible couple potentials for H and OH, respectively. Since the equivalent redox potential is a kinetic, rather than a thermodynamic quantity, however, the free energies determined the direction of the several reactions, but not their rates, or the value of the resulting mixed potential. Clark observed that a platinum electrode in a solution swept by hydrogen showed no detectable change in potential when the gamma source was applied. This demonstrates that, at 85°, the electrode processes were unaffected by the hydrogen atoms and hydroxyl radicals produced, or, in other words, that the normal exchange current of the process $(\mathrm{Pt})\mathrm{H}_2 \rightleftharpoons 2\mathrm{H}^+ + 2e^-$ was sufficient to prevent a change of potential by any added electrode reactions due to hydrogen atoms or other active species formed under irradiation. According to Veselovsky, the normal potential of the hydrogen electrode is almost realized when an acidic solution is irradiated after being freed of dissolved gases. These results agree in indicating that hydrogen atoms disappear so rapidly in one way or another that they do not disturb the equilibrium among H_2, H, H^+, and electrons at the metal-solution interface.

Removal of hydrogen atoms as a chief reactant still does not explain the observed potential, however, since the reversible normal potential of such a couple as $\mathrm{OH} + \mathrm{H}^+ + e^- \rightarrow \mathrm{H}_2\mathrm{O}$ would be approximately 3 V. noble to a hydrogen electrode in the same solution. It is therefore evident on electrochemical grounds that OH radicals also disappear rapidly. It is to be observed, further, that both the value of the equivalent redox potential in the presence of air or radiolytic oxygen and its dependence on pH are approximately the same as those indicated by a platinum electrode in a dilute solution of hydrogen peroxide[10]. From these observations it appears that, although short-lived atoms and radicals may participate in both homogeneous and electrode reactions, the principal electrochemical effects may be ascribed to molecular hydrogen and oxygen and hydrogen peroxide. The mixed potential indicated by any given electrode therefore depends upon both the polarization characteristics of the electrode, including its surface state, and also any conditions that alter the surface concentrations of these radiolytic products. The value 0·85–0·90 V. noble to the hydrogen electrode is to be considered a unique property of the system only when a reversible electrode is used and when air is present or radiolytic products are allowed to accumulate in a steady state. The potential is independent of the identity of the redox system, so long as a steady state is reached; but its measurement is facilitated by having such a system present to give stability to the potential.

I acknowledge helpful discussions with E. H. Taylor, C. J. Hochanadel, F. A. Posey, and K. E. Heusler of this Laboratory, with Prof. Milton Burton, of the University of Notre Dame, and with Prof. F. S. Dainton and Dr. E. Collinson, of the University of Leeds.

STEROL ANALYSIS BY GAS CHROMATOGRAPHY

By R. K. BEERTHUIS and J. H. RECOURT

Unilever Research Laboratory, Vlaardingen, Holland

USE of gas chromatography in the analysis of sterol mixtures by itself or as a supplement to other methods of separation may yield more detailed results than have been possible up to now. The relative simplicity with which in general very effective separations can be rapidly obtained—in which case direct quantitative determination is frequently possible—is a great advantage of this technique.

We have investigated the possibilities of the analysis of sterols using model substances and natural mixtures. In view of the very low volatility of sterols, high column temperatures had to be used; but in the high-temperature range the choice of the stationary phase is considerably limited.

'Apiezon *L*' and alkathene appeared to be completely unsuitable for this purpose. The sterols eluted as broad, asymmetric peaks. With silicon oil, on the other hand, completely symmetrical peaks were obtained.

We used the residue of a molecular distillation at 200° C. and 2µ pressure of Midland silicones No. 550. The carrier, 'Celite 545', was treated with acid to remove traces of metal, screened to a suitable particle size and treated with dichloro-dimethyl silane as described for 'Hyflo'[1] to make it as inert as possible.

At present we have only investigated separations on a relatively short column (length: 90 cm.; internal diameter: 4 mm.) packed with 20 per cent by weight of silicone oil on 'Celite'. The best results were obtained with 'Celite' having a particle size of 150–178µ. The column was conditioned at a working temperature (287° C.) for 2 days. During this period the column was repeatedly vibrated and filled up with packing until a constant level had been obtained. The substances were brought on to the column as such in a small perforated stainless steel basket, or dissolved in methyl myristate using a capillary pipette. As detector the gas density balance[2] was used, which, together with the column, was placed in an electrically heated air-bath. With the help of the internal standard technique, it was found that the elution of the investigated substances proceeded quantitatively.

Infra-red recordings of cholesterol, before and after passing the column, displayed no differences. It is evident, therefore, that no structural changes occur at this high temperature.

Fig. 1 shows the separation of cholesterol, 7-dehydrocholesterol, ergosterol and stigmasterol. Because of the conjugation in the *B*-ring of 7-dehydrocholesterol there is such a difference in volatility with cholesterol that these two substances can be separated almost completely. The influence of the length of the side-chain upon the retention time appears from the separation of ergosterol, stigmasterol and cholesterol. Cholesterol was also completely separated from technical sitosterol (supplied by Messrs. S. A. F. Hoffmann-La Roche and Co., Ltd., C.O. Basel). The sitosterol, however, was found to consist of at least three components. Separations can also be effected of sterol esters (Fig. 2).

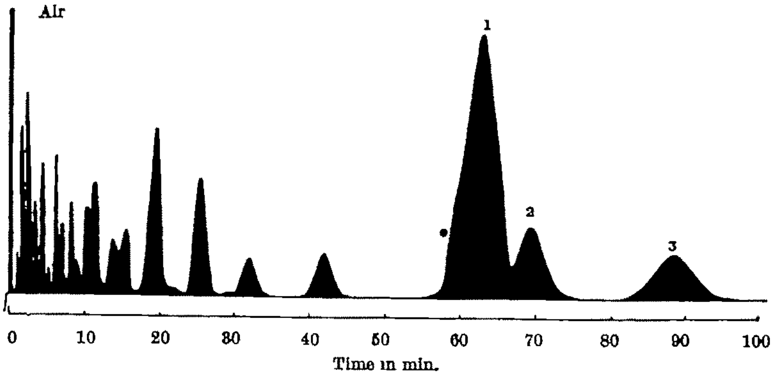

Fig. 3. Conditions (see Fig. 1). Zone *D* from rat fæces: (1) coprostanol; (2) probably cholestanol; (3) methostenol

The following example shows that with gas-chromatography it is possible to obtain separations which can only be indirectly achieved when other methods are applied.

When feeding rats a fat-free diet the fæces contain cholesterol, cholestanol, Δ^7-cholestenol, 7-dehydrocholesterol, coprostanol, and methostenol. The analyses of these sterols have been worked out by Coleman, Wells and Baumann[3,4]. Application of their chromatographic methods results in the separation of two main sterol bands, the so-called zones *C* and *D*. Zone *D* contains at least two sterols: coprostanol and methostenol. These two substances can be determined individually by means of the Liebermann–Burchard reaction. Coprostanol is the slow- and methostenol the fast-acting component. The structure of methostenol appeared to be: 4 α-methyl-Δ^7-cholesten-3 β-ol[5].

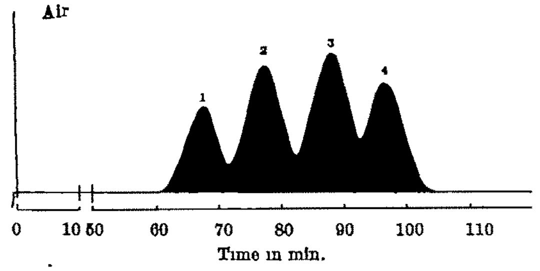

Fig. 1. Conditions: column, 90 cm. × 4 mm.; packing, 'Celite' 150–178μ; silicon oil, 4.1; temperature, 287° C.; overpressure on top of the column, 53 cm. mercury; flow-rate, 24 ml. N_2/min. Separation of: (1) cholesterol; (2) 7-dehydrocholesterol; (3) ergosterol; (4) stigmasterol

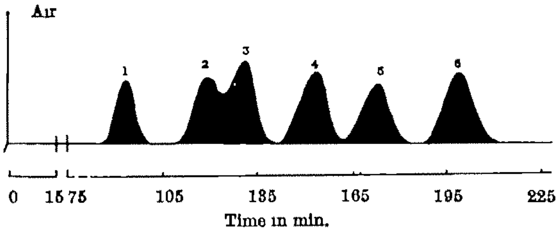

Fig. 2. Conditions (see Fig. 1). Separations of esters of cholesterol: (1) acetate; (2) propionate, (3) isobutyrate; (4) butyrate, (5) isovalerate; (6) valerate

Coprostanol and methostenol can only be separated chromatographically via the *p*-phenyl azobenzoates, which is a time-consuming process. By means of gas-chromatography, however, these sterols can be rapidly and quantitatively separated and determined.

Fig. 3 shows the chromatogram of the above-mentioned band *D* from the unsaponifiable fraction of rat fæces. The peaks in the sterol range are indicated as 1, 2 and 3. These three substances were collected individually and their behaviour with respect to the Liebermann–Burchard reagent investigated. Coprostanol, the slow-acting sterol, is represented by peak 1, methostenol as fast-acting sterol by peak 3.

The substance in peak 2, with a retention time equal to that of cholestanol and cholesterol, gave a negative Liebermann–Burchard reaction. On application of a modified chromatographic procedure based on the method of Coleman *et al.*[4] zones *C* and *D* can be eluted. This proceeds in such a way that on elution of the bands zone *C* leaves the column immediately after zone *D*. Cholestanol is already present at the beginning of band *C* and slight overlapping of the two zones is possible. Cholestanol also gives a negative Liebermann–Burchard reaction and therefore it is highly probable that the substance in peak 2 is cholestanol originating from zone *C*.

The gas-chromatographic separation obtained illustrates the great influence of methyl addition in the *A*-ring of the cholestenol molecule upon the retention time. At the same time it appears that the stereoisomers cholestanol and coprostanol are completely separated.

Table 1 contains the relative retentions of the sterols mentioned as well as of some higher hydrocarbons.

From our results it appears that sterols which differ in the total number of carbon atoms can not only be readily separated but can also be determined

Table 1. RETENTION VOLUME RELATIVE TO CHOLESTEROL ON SILICON OIL

Coprostanol	0·9	Cholesterylacetate	1·42
Cholesterol	1	Tetratriacontane	1·45
Cholestanol	1	Cholesterylpropionate	1·83
Δ^7-Cholestenol	1·14	Cholesterylisobutyrate	2·0
7-Dehydrocholesterol	1·14	Cholesterylbutyrate	2·32
Methostenol	1·28	Cholesterylisovalerate	2·64
Ergosterol	1·30	Cholesterylvalerate	3·02
Stigmasterol	1·36	Octatriacontane	3·96

quantitatively, and if necessary the various fractions be used for further identification.

The plate number computed for cholesterol was 2300.

The resolution obtained can be improved by applying longer packed or coated capillary columns in combination with more sensitive detectors.

Our thanks are due to Mr. P. Smits and Mr. H. Dronkers, who carried out the group separation of the sterols. Further, we are greatly indebted to the management of Unilever N.V. for permission to publish these results.

DETOXICATION DURING SECONDARY GROWTH IN PLANTS

By C. M. STEWART

Division of Forest Products, Commonwealth Scientific and Industrial Research Organization,
69-77 Yarra Bank Road, South Melbourne

PLANTS, in contrast with animals, do not possess well-defined organs for the excretion of potentially injurious metabolic products. However, it is obvious that means must exist whereby toxic substances are rendered non-toxic or, if toxic, are 'excreted' to locations within the plant where the toxicity of the substances is of little consequence. For example, it is well known that succinic and oxalic acids are immobilized, in special parenchyma cells of secondary xylary tissues, as crystals of aluminium succinate and calcium oxalate.

In general, substances with reactive groups (whether they be toxic or non-toxic) are transported usually in an inactivated state to the regions of active secondary growth. For example, sugars are transported chiefly as sucrose, coniferyl and sinapyl alcohols as glycosides, and so on. These products of photosynthesis are soluble and, for purposes of permanent or temporary storage, they are converted, enzymatically, to the polymolecular ergastic substances of the cell wall (cellulosic and non-cellulosic polysaccharides and lignin) and the materials extraneous to the cell wall (tannins, kinos, lipids, starch, etc.).

High concentrations of acids and especially of phenolic substances exhibit an inhibitory effect or are toxic to cambial tissues. For example, Jacquiot[1] has shown that tannins inhibit the proliferation of isolated fragments of cambial tissues from *Quercus* and *Castanea*. In agreement with this observation, it has been found, for *Eucalyptus regnans*, that tannins are present in minimal amounts in the cambial zone and that the amounts increase on each side of the cambium ; this evidence was taken as an indication that tannins are waste materials which are excreted to each side of the cambium and eventually accumulated in the tanniniferous parenchyma cells of the phloem (eventually transformed to the rytidome and thus periodically shed), and, via the parenchyma cells of the sapwood, in the dead cells of the heartwood[2]. Thus the formation of tannins and their excretion as outlined above may be, primarily, a means of 'detoxication' of excess phenolic substances. This does not mean that the tannin precursors (possibly by-products formed during the biosynthesis of lignin[3] or flavonoid compounds[3]) or the tannins themselves may not have important physiological functions in plant life ; for example, it has been suggested that they may act as antioxidants or as inhibitors of fungal growth[4].

Again, lignin is a polymer formed from phenolic base units. Hence lignification, whether it proceeds by the utilization of phenolic substances from the nutrient phloem 'sap' stream ('detoxicated' coniferyl or sinapyl alcohols[5], flavonoid compounds[6], etc.) or by the utilization of lignin precursors produced within the developing cell either during its normal active life[7] or during its senescence[8], may be essentially a process of 'detoxication'. A secondary 'evolutionary' function of lignin may be to give rigidity and compressive strength to the cell walls of xylary and other plant tissues ; however, plant tissues tend to be brittle when the lignin content is high[4,9].

There is much indirect evidence which indicates that, during lignification, the lignin becomes chemically bonded to the non-cellulosic polysaccharides of the primary, and outer portions of the secondary, cell walls. Much of the evidence suggests that the lignin is attached, by ester bonds, to the uronic acid units. For example, it is known that ruthenium red, a stain specific to carboxyl groups[10] in mature fibre cell walls, stains the intercellular layer and primary cell wall more intensely than any other portion of the cell wall ; in the case of *Eucalyptus regnans* wood, the intensity of staining diminishes as lignification proceeds (Wardrop, A. B., unpublished work) and becomes almost zero in the mature fibre cell wall ; analogous staining behaviour has been observed during the lignification of *Pinus sylvestris*[11]. When sections of mature wood of *E. regnans* are hydrolysed with dilute acids or alkalis, the red-staining potentialities increase with time of hydrolysis, the alkali being about 10^3 times as effective as acid in this respect (Stewart, C. M., Watson, A. J., Dadswell, H. E., and Kottek, J. F., unpublished work). Also, when holocellulose, prepared from *E. regnans* wood, is treated with dilute alkali (0·08 per cent sodium hydroxide for 1 hr. at 98°) the residual lignin is removed[12].

Many workers have shown that the 4-O-methyl-D-glucuronic acid units of the non-cellulosic polysaccharides of woods are attached glycosidically to the xylose units of the polymer chains. Thus, during lignification, lignin units may become attached to the uronic acid residues by the formation of 'lignyl' 4-O-methyl-D-glucuronate side-chains linked through the 2-O- or 3-O-positions on to the xylose units of the main chains of the glycosan uronides ; this linkage process, and the possible further addition of lignin units to those already incorporated in the side-chains, may represent the 'detoxication' mechanism which is applicable to the plant cell wall. During animal metabolism, many aromatic substances appear in the urine as derivatives of D-glucuronic acid; for example, alcohols and phenols appear as β-glycosides (for example, phenyl β-D-glucosiduronic acid) and carboxylic acids appear as β-hemiacylals (for example, benzoyl β-D-glucosiduronic acid)[13]. Hence uronic acids may serve as 'detoxication' agents during the metabolism of both plants and animals.

Perhaps other examples of 'detoxication' during the secondary growth of plants could be cited. For example, excess aliphatic acids such as formic and acetic acids, which do not form insoluble salts, may be immobilized by their attachment, as formyl or acetyl groups, to certain of the cell-wall polysaccharides; glycosan uronides, especially in hardwoods, have relatively high contents of acetyl groups, equivalent in some cases to about 25 per cent acetylation[12]. Again, alcohols may be immobilized as O-alkyl or alkoxy groups attached either to cell-wall components or to extraneous substances.

From the above discussion it will be noted that there are several possible general means of 'detoxication' and/or excretion which may operate within a plant. Normally, while in solution, the toxic substance is 'detoxicated' by the formation of a non-toxic derivative, usually a glycoside. If the production of such substances were to continue, without some means of lowering their concentration, the cell fluids would become extremely viscous because of the high concentration of substances in solution. A mechanism of preventing the formation of high concentrations must exist; this mechanism, in general, seems to depend upon polymerization of the soluble substances to ensure temporary or permanent 'detoxication' of reactive toxic groups (during the polymerization reactions), with parallel increased insolubility and deposition in the walls or cellular contents of cells, which will eventually be isolated from the regions of active growth.

In the case of substances such as aliphatic acids which neither form glycosides nor readily polymerize, two means of 'detoxication' seem possible: first, the formation of insoluble salts which are stored in special crystalliferous parenchyma cells; and, secondly, attachment as acyl groups to the glycosan uronides, excess acids perhaps being excreted to the bark or heartwood. It should be noted, especially in old xylary tissues, that the acids may be re-liberated from acyl groups by autocatalysis, with consequent damage to the tissues resulting from prolonged hydrolytic reactions (Stewart, C. M., Watson, A. J., Dadswell, H. E., and Kottek, J. F., unpublished work).

COBALT IN NITROGEN FIXATION BY A LEGUME

By Prof. H. M. REISENAUER

Department of Agronomy, Washington State University, Pullman, Washington

OUR understanding of cobalt as a micro-nutrient element required by animals and various micro-organisms centres around the role of vitamin B_{12}. This vitamin is required by most animal species[1] in the formation of hæmoglobin and may be concerned with protein metabolism[2]. Most workers agree that vitamin B_{12} is synthesized only by micro-organisms[1]. Many micro-organisms require preformed B_{12} (refs. 3–5); others, including *Rhizobia*[6], produce the vitamin.

Cobalt has not been demonstrated as being a requirement for the growth of higher plants, although it has been shown to be essential for blue-green algae[7]. With higher plants, cobalt supplements have been reported to increase growth of the rubber plant and tomatoes[8] and to increase elongation of pea stem sections[9,10]. Recently, Ahmend and Evans[11] have suggested that soy-bean plants grown with symbiotically fixed nitrogen as their only source of this nutrient were "distinctly benefited" from small quantities of cobalt. The experiment reported here makes it quite clear that enormous reductions in the amount of nitrogen fixed by inoculated lucerne plants result when culture solutions are sufficiently purified and controlled with respect to cobalt contaminants. Other experiments in progress at the present time at the University of California, where higher degrees of control have been obtained more recently, are giving further evidence of correspondingly greater yield differentials between inoculated lucerne plants grown on cobalt-deficient and cobalt-sufficient culture solutions.

An essential role of cobalt in symbiotic nitrogen fixation and possibly in all biological nitrogen-fixation processes is suggested by the following information. The nodules of legume plants contain hæmoglobin very similar to that of animal blood[12,13]. Nitrogen fixation is directly related to the hæmoglobin content of the nodule[14–17]. Vitamin B_{12} has been found to be concentrated in the root nodules of legume plants and particularly those that contain hæmoglobin[18]. The synthesis of hæmoglobin in the nodule is a result of the symbiotic relationship since it cannot be synthesized by either the plant or the micro-organism alone[12]. A possible relationship of cobalt to a biological nitrogen-fixing process is suggested from the results of Holm-Hansen and co-workers[7]. In their demonstration of a cobalt requirement for the growth

Table 1. NITROGEN FIXED BY *Medicago sativa* (LUCERNE) WITH AND WITHOUT COBALT SUPPLEMENTS

of blue-green algae, these workers noted that upon their cultures with low cobalt content, growth reduction of the nitrogen-fixing species was more pronounced than for the species requiring combined nitrogen.

The experiment reported here was undertaken to observe whether or not cobalt supplies could effect nodulation and symbiotic nitrogen fixation in lucerne (*Medicago sativa*). The culture solutions were restricted as to nitrogen salts and contained 1·3 m*M* nitrogen, 2·0 m*M* phosphorus, 3·1 m*M* potassium, 4·0 m*M* calcium, 1·0 m*M* magnesium, 5·0 μ*M* manganese, 2·0 μ*M* zinc, 0·5 μ*M* copper, 17·5 μ*M* iron (from Fe-ethylenediaminetetraacetic acid), 5·0 m*M* sulphur, 25 μ*M* boron, 0·5 μ*M* molybdenum, 22·5 μ*M* chlorine and 1·0 gm. calcium carbonate per litre. Treatment variables are described in Table 1. All chemicals used in formulating the 'purified' cultures were treated to remove contaminant cobalt in so far as possible with the purification processes mentioned here. All water, volatile acids, bases and organic reagents used were redistilled in 'Pyrex' glass apparatus. Solutions of 2·0 *M* calcium nitrate, 1·0 *M* $K_{1\cdot1}H_{1\cdot9}PO_4$ and 0·5 *M* potassium sulphate were purified by iron-oxinate coprecipitation at *p*H 5·1–5·2 as described by Hewitt[19]. Dithizonate extraction at *p*H 8·5 was used in preparing low cobalt solution of magnesium sulphate. Iron was purified by extracting as ferric chloride with ether from hydrochloric acid solution[20]. Reagents supplying the micro-nutrients, except iron, and sodium chloride were twice recrystallized before use. The calcium carbonate added to maintain the reaction of the cultures above *p*H 6 was precipitated from purified calcium nitrate solution.

Lucerne plants were grown in a glasshouse at Berkeley during May and June. The treatments were arranged in a randomized block design and repeated four times. Three 10-day-old lucerne plants were transplanted to 2-litre, continuously aerated cultures. The following day the pots were inoculated with 1 ml. of a suspension containing a mixture of two effective *Rhizobia* strains—approximately 10^4 bacteria per pot. The plants were harvested six weeks after transplanting, separated into tops, roots and nodules, dried and weighed. Total nitrogen was determined in all plant parts.

The fixed nitrogen supplied by the culture solutions was adequate for normal growth of the plants of all treatments for four weeks. In the fifth week nitrogen deficiency symptoms developed on the plants of the 'not inoculated' treatments as well as those of the 'inoculated-minus cobalt' treatments. Nodules were visible on the roots of the inoculated plants within three weeks. No nodules were found on the plants which were not inoculated. Nodule counts made four weeks after transplanting showed the 'plus cobalt' and 'unpurified' cultures as having plants with larger nodules than the plants deprived of cobalt. The 'not inoculated' and 'minus cobalt' plants displayed characteristic symptoms of nitrogen starvation, whereas inoculated plants having cobalt supplements were green and obviously not short of nitrogen.

Whole plant weights, nodule weights and the nitrogen content of the plants are given in Table 1. Addition of cobalt to the 'purified' cultures increased plant growth by 66 per cent during an evident stress period of only two weeks. This effect of cobalt is significant at odds of 2,000 : 1. Similarly, nodule weight was doubled—significant at odds of 200 : 1.

In the presence of *Rhizobia* but without added cobalt the plants fixed 34 mgm. of nitrogen without sodium chloride and 27 mgm. of nitrogen with sodium chloride. However, with cobalt added the corresponding cultures fixed 237 and 154 mgm. of nitrogen, respectively. The variable of 0·5 m*M* sodium chloride in the culture solution which resulted in a lesser amount of nitrogen being fixed in each case was introduced into the experiment in order to give other levels of plant growth not associated with cobalt. Within this experiment, however, cobalt was by far the overriding factor in determining the amount of nitrogen fixed by inoculated *Medicago sativa*.

The magnitude of the results obtained here distinctly implies an essential role of cobalt in symbiotic nitrogen fixation. Additional results from this and an expanded confirming experiment are to be published elsewhere.

This work was conducted during the tenure of a lectureship with the Kearney Foundation of Soil Science, University of California, Berkeley, which is gratefully acknowledged. I am indebted to C. M. Johnson, C. C. Delwiche and P. R. Stout for their assistance and valuable suggestions.

PHYSICS

The Possibility of a Self-sustaining Corbino Disk

An impressed radial current and an axial magnetic field combine in the Corbino disk[1] to induce a circulating component of current due to the Hall effect. Whichever sense the axial field may have, it is aided by the field of the circulating currents themselves, provided that the radial current is always inwards. This applies to a material with the normal sign of Hall coefficient for *n*-type conduction.

Without the impressed axial field, the disk would be a two-state element, which could form the basis of a digital computer. The two states would be self-sustaining current vortices of opposite spin. The existence of such vortices is suggested by a solution of the field-equations for an indefinitely thin disk of infinite radius, immersed in a medium of permeability μ :

$$J_r = \frac{I}{2\pi r.\delta z} \qquad J_\theta = \sigma.E_\theta$$

$$E_\theta = R.J_r.B_z \qquad J = \frac{\text{curl } B}{\mu.\eta_0}$$

where r,θ,z are cylindrical co-ordinates; I, total current (amp.); J, current density (amp./sq. metre); E, electric field intensity (volts/metre); R, Hall coefficient (metre^3/coulomb); σ, conductivity (mho/metre); $\eta_0 = 4\pi \times 10^{-7}$ henry/metre.

B_z, E_θ and J_θ all satisfy an equation of the form :

$$\frac{dB_z}{dr} + \mu.\eta_0.\frac{\sigma.R.I.B_z}{2\pi r.\delta_z} = 0$$

which has the solution : $B_z = A.r^{-k}$

where A is a constant of integration, and k is $\sigma\mu\eta_0 R.I/2\pi\delta z$.

More significant than the increase towards the centre in the flux density B_z is the increase in total flux within a ring of width δr when $k \geqslant 1$. This establishes a critical value for the radial current, above which amplification and regeneration are possible. A transformer exploiting the creation of a secondary flux in excess of the primary flux would behave as a magnetic power amplifier. The introduction of a magnetic feedback path in such a transformer would lead to a bi-stable trigger circuit.

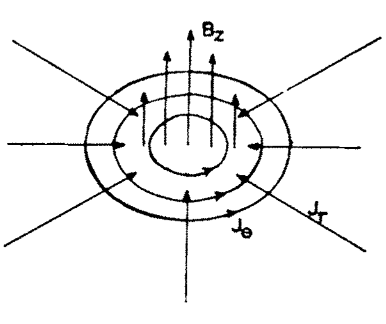

Fig 1. Axial magnetic field in relation to the radial and circulating components of the current density

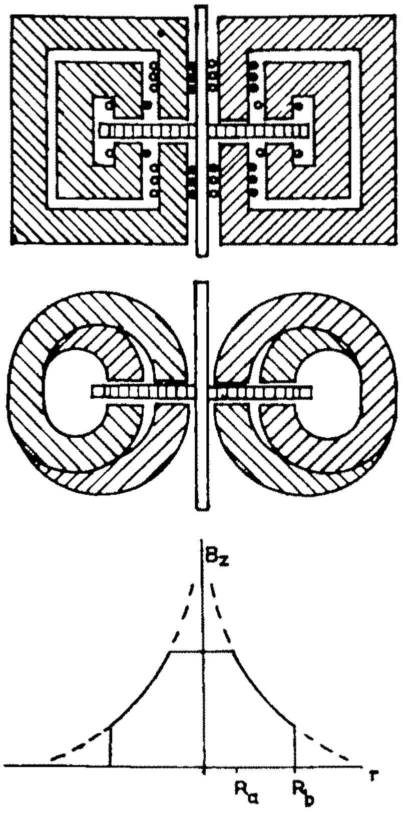

Fig. 2. Top : A magnetic amplifier having an input coil to provide B_z at R_b and an output coil at R_a. (Permeable material is diagonally shaded and Hall-sensitive material vertically shaded. The radial current is introduced by a conducting rim on the disk and is removed along the two halves of the axis)
Centre : A magnetic feedback circuit for a two-state element. (If a fraction f of B_z at R_a is returned to R_b, the fields become self-sustaining when $k = \frac{\ln(f)}{\ln(R_a/R_b)}$
Bottom : Axial flux density, circulating current density and circulating electric field-strength for an infinite disk : - - -. The same for a finite disk : ———

A vital question is whether the critical current is necessarily destructively large, as it would be for the conductivities and small Hall coefficients of ordinary metals at room temperature. However, products of conductivity and Hall coefficient of the order unity have been observed in germanium alloys at low temperatures[2]. Assuming that, by restricting the thickness of the disk to 0·01 per cent of the magnetic path, an effective permeability of 10^4 could be maintained, a current of 5 amp. per cm. of magnetic path would be required for criticality.

Rheological Properties of Barytes Suspensions

THE rheological properties of suspensions, which are used in coal preparation by dense-medium washing, are being studied. Initially, suspensions of barytes prepared by ball milling and containing particles of all sizes less than 250μ, and in most cases less than 100μ, were investigated. The effects of the concentration of solids and of the particle size of the solids on the consistency curve have been studied. It is hoped to extend the work to more complex systems containing three solid components (barytes, coal and shale) each or all of which may be deficient in smaller-sized particles. The present communication is intended to direct attention to some interesting features of the results obtained.

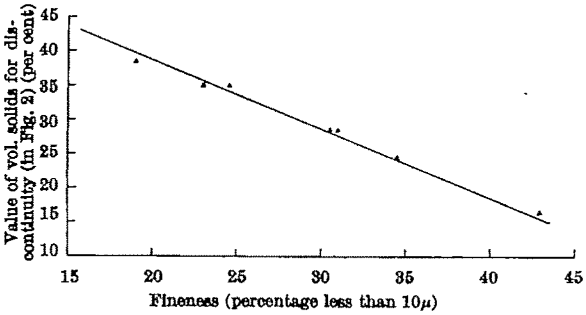

Fig. 3

The work was carried out using a Ferranti portable (rotating cylinder) viscometer[1]. This enabled the consistency to be studied over a fairly wide range of shear-rates (68–950 sec.$^{-1}$). Readings were taken immediately after thorough stirring, which could lead to the presence of a third phase (air bubbles) in the system. However, it is likely that suspensions used in practice will also contain air bubbles. All the consistency curves reveal that the suspensions are Bingham fluids over the range of shear rates used.

From the consistency curves, the yield point and plastic viscosity were estimated for suspensions containing different solids concentrations and containing solids over a range of fineness. For the suspensions studied, the results are illustrated in Figs. 1 and 2. The concentrations, at which the discontinuity in the plastic viscosity vs. concentration relationship occurs, have been found to bear a linear relation to the fineness of the barytes as expressed by the weight less than 10 microns (Fig. 3). This suggests that the phenomenon is due to the irregularities in the particles carrying immobile layers of liquid as proposed by Ward and Whitmore[2], and should enable the mean thickness of the layer to be estimated.

In earlier investigations a Gallenkamp universal torsion viscometer had been used in viscosity measurements on suspensions. A study of mode of operation and the results obtained on this instrument and the rotating cylinder viscometer lead us to conclude that, to a first approximation, the readings on the torsion viscometer (using 11/16-in. and 1⅝-in. cylinders) were a measure of the yield point of the suspensions (see Fig. 4).

An Energy Band Interpolation Scheme, with Application to Body-centred Cubic Lithium

An interpolation scheme has been developed for the calculation of the energy bands in solids, using plane wave expansions of the wave functions and accurately known values of the energy-levels at high-symmetry points of the Brillouin zone. For valence electron states having the same symmetry as those of the ion cores, these expansions must be modified by the use of an additional repulsive pseudo-potential V_r. Of various suggested forms[1] of V_r, that found most useful was that of Gáspár[2] and Antončík[3], an extension to metals of that derived for atoms by Gombás[4]. By using only a small number of terms in the expansions it was then found possible to reproduce the energy-levels at high-symmetry points with at least the accuracy to which they had been originally determined. The levels at a large number of general points of the zone were then calculated, and, in order to obtain the density of states $N(E)$, these energy values were fitted by a symmetrized triple Fourier expansion of $E(k_x,k_y,k_z)$.

The method has been applied to body-centred cubic lithium, for which energy-levels at high-symmetry points have been obtained by Glasser and Callaway[5,6], using the orthogonalized plane wave method and the corrected Seitz potential[7], and with a stated accuracy $\pm 0{\cdot}05$ Ry. The number of terms used in the plane wave expansions to reproduce these levels was taken to be equal to the degeneracy of the corresponding level in the free-electron approximation (for example, 6 for the lowest state H_1, in the notation of Bouckaert *et al.*[8]). For the *s*-like levels V_r involves the 1*s* wave function of the ion core, which was chosen to be hydrogenic with a screening constant which was taken to be a disposable parameter, fixed by giving agreement with the lowest state Γ_1. To reproduce the *p*-like levels, the truncation of the plane wave expansions was brought about by using as a correction a very small further pseudo-potential, while the *d*-like levels could be reproduced by using the Seitz potential alone. The lower levels thus calculated agreed with those of Glasser and Callaway to within their stated accuracy. Levels were then calculated at general points within the first zone on a lattice $(a/2\pi)(k_x,k_y,k_z) = (1/10)n$ $(n = 1,2\ldots)$ by using an appropriate number of terms of the plane wave expansion, and the first 22 Fourier coefficients of $E(k_x,k_y,k_z)$ obtained by least squares. Finally, $N(E)$ was obtained by numerical integration. The calculations were carried out on the Mercury Computer of the University of London.

Fig. 1 shows the calculated $N(E)$ curve, with E_F, the Fermi energy, $-0{\cdot}425$ Ry., and E_N, the lower energy at N, $-0{\cdot}400$ Ry., N being the point on the surface of the first zone nearest to its centre Γ. Since $E_F < E_N$, the calculation thus shows that the Fermi surface does not touch the zone boundary; however, $(E_N - E_F)$ is only equal to $0{\cdot}025$ Ry., which is within the accuracy of Glasser and Callaway. The broken curve on Fig. 1 gives the $N(E)$ curve

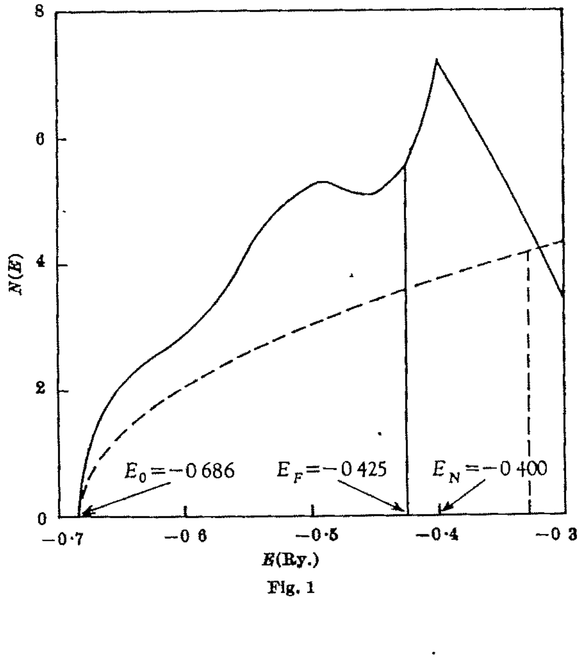

Fig. 1

for free electrons. The energy surfaces near Γ can be expressed as[7]:

$$E(\mathbf{k}) = E_0 + E_2k^2 + E_4^{(1)}k^4 + 5E_4^{(2)}(k_x^2k_y^2 + k_y^2k_z^2 + k_z^2k_x^2 - 1/5k^4)$$

where $E_0 = -0{\cdot}686$, $E_2 = 0{\cdot}754$, $E_4^{(1)} = -0{\cdot}064$, $E_4^{(2)} = -0{\cdot}146$, and where E_2 corresponds to an effective mass at Γ, $m^* = 1{\cdot}32\ m_e$, and $E_4^{(2)}$ gives a measure of the anisotropy. Previous values of these constants are given in refs. 6 and 9. The value $E_F - E_0 = 0{\cdot}261$ Ry. compares with a value 0 235 Ry. based on the soft X-ray emission spectrum[10]. The calculated low-temperature electronic heat coefficient is $2{\cdot}38 \times 10^{-4}$ cal. mol.$^{-1}$ deg.$^{-2}$, compared with the observed value[11] $4{\cdot}18 \times 10^{-4}$, which was, however, not obtained for body-centred cubic lithium.

The method is now being applied to other metals including sodium, potassium, titanium and beryllium, and fuller details will be published elsewhere.

Trace Analysis by X-Ray Fluorescence using Ion Exchange Resins

THE analysis of trace elements in concentrations of a few parts per million, or less, by X-ray fluorescence spectrography has hitherto not been practicable, mainly as a result of the relative weakness of the emitted spectra. Grubb and Zemany[1] have obviated this difficulty by showing that traces of cobalt at levels of 1 μgm./l. may be analysed by first adsorbing the element on to a small piece of cation membrane and irradiating this in an X-ray spectrograph. The long equilibration times involved (16–48 hr.) have, however, precluded the general application of their method in a wider field, particularly in process control, where the time-factor is important.

The method which we have developed is based on a similar concentration step, but the element to be determined is collected on an ion-exchange resin (granular or liquid), after which the resin is irradiated directly in the X-ray spectrograph. A number of elements may thus be collected and determined simultaneously without the necessity of time-consuming separations. We have found that rapid equilibrium with solid resins is attainable, provided that the resin is soaked beforehand. Equilibrium with liquid resins is even faster. The relative amounts of resin and solution are so chosen that the enrichment ratio brings the concentration of the element on the resin within the range where it can be determined directly by X-ray spectrography. Provided that the variation in particle size of the solid resin is small, no extra variance is introduced in the results by distributional variations in the resin bed. Where relatively large amounts of co-adsorbed elements give rise to interferences, such as absorption or enhancement of the measured radiation, the effects can be overcome by the use of suitable internal standards. The voids between the solid resin particles are filled with the reference element in non-adsorbing form. The reproducibility of the results obtained justify the introduction of standards in this way.

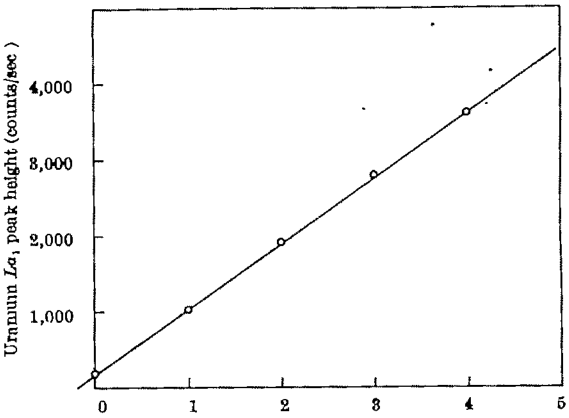

Fig. 1. Extraction of uranium from 'barren' solution with solid resin, '*AG–1X*'

The determination of uranium in barren sulphate effluent, from the ion-exchange columns in the Witwatersrand uranium industry, serves as a good illustration of this technique. (Detailed results will be published elsewhere.) The major ionic constituents of these solutions are:

Fe^{2+} (2–3 gm./l.) Fe^{3+} (2–3 gm./l.)
Mn^{2+} (4–6 gm./l.) Al^{3+} (4–6 gm./l.) and
SO_4^{2-} (~20 gm./l.) at a *p*H of about 3

The uranium content varies between 0 and 3 p.p.m. 500 ml. of this solution is shaken for 5 min. with 2 gm. (dry weight) of '*AG–1X*' anionic resin in sulphate form which has been soaked beforehand in 0·25 *M* ammonium sulphate solution. The resin is filtered by

3·76	3·60	3·40	3·50
4·35	4·30		

suction, washed over into a suitable liquid sample holder[2] and irradiated (Philips high-intensity molybdenum tube). The linearity obtained when making standard additions of uranium to barren solutions is illustrated in Fig. 1. Iron, probably co-adsorbed as negative ferric sulphate complexes, absorbs the uranium-$L\alpha_1$ radiation, so that the use of internal standards is advisable where the iron content of the solutions tends to fluctuate. (In practice, we have found this unnecessary as the iron concentration in these barren solutions remains constant within narrow limits.) Fig. 2 illustrates the feasibility of using alcoholic bromobenzene and aqueous yttrium sulphate as internal standards. Under the above conditions about 90 per cent of the uranium in a solution containing 2 p.p.m. is extracted with good reproducibility (standard deviation 1–2 per cent).

Good extraction is also possible with anionic liquid resins (for example, 'Amberlite *LA*–2'). The sensitivity is somewhat lower (see Figs. 1, 3), as the highest practicable concentration ratio is only about 50. The linearity obtainable when extracting 500 ml. of 'barren' solution with 10 ml. 20 per cent '*LA*–2' in kerosene is shown in Fig. 3. Although much less iron is co-extracted in this case, so that absorption effects are not serious, we have established that internal standard procedures can also be applied here by using bromobenzene in kerosene. Typical results are given in Table 1. The accuracy of both variants of the method is estimated at 5 per cent on 1 p.p.m. uranium, the main source of error residing in the statistical counting error due to the unfavourable peak to background ratio. The limits of detection, under the above conditions, are estimated to be 0·1 p.p.m. uranium using solid resin, and 0·2 p.p.m. using liquid resin.

As the method is also applicable to cationic resins, we believe that this technique extends the scope of X-ray fluorescent analysis far beyond its present limits, and its rapidity should render it useful for the routine trace analysis of a wide range of elements.

Micromosaic Patterns in Single Crystals of Potassium Chloride containing Barium Chloride

Dislocation networks generated in alkali halide crystals when subjected to mechanical strain have been rendered visible by 'decoration' with colloidal aggregations of colour centres[1] and with silver[2]. Amelinckx *et al.*[3] obtained micromosaic patterns in sodium chloride crystals containing sodium or barium chloride and Hedges and Mitchell[4] in silver bromide containing excess silver.

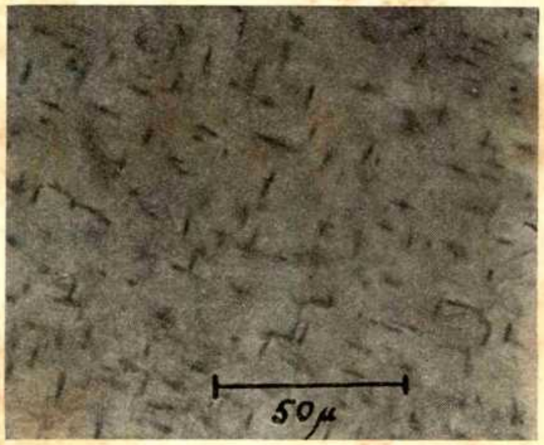

Fig. 1

In the present work barium chloride in concentrations varying from 5×10^{-5} to 10^{-2} barium/potassium atoms was added to melts of potassium chloride and single crystals grown from the melt by the Kyropoulos method[5]. The crystals were cleaved to produce specimens of about 0·5 mm. thick and microphotographs made of interior planes at a magnification of 500. It was found that crystals containing about 5×10^{-4} barium/potassium showed throughout the interior a pattern consisting of a network of lines some 5–10μ long (Fig. 1). Pure crystals showed no such patterns. Occasionally, deep within the crystal, was seen a pattern such as that shown in Fig. 2, which gave the impression of voids within the crystal some 5μ or less in depth and some hundreds of microns in length. It might be supposed that such voids might be generated as a means of reducing the strains set up by the relatively high impurity content or by the unavoidable thermal strains in the formation of the crystals. It has not been possible so far to anneal out such voids even after many hours heating and of subsequent cooling to room temperature at a rate of about 5 deg. C. per

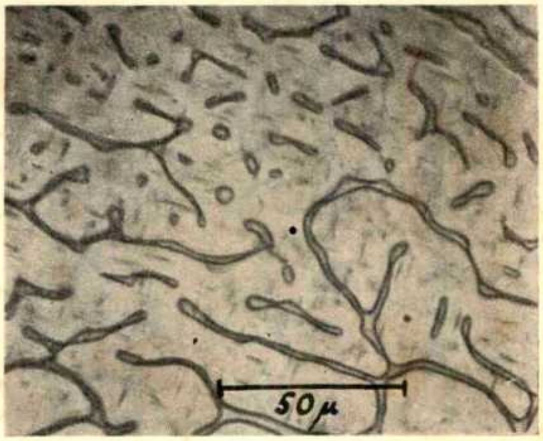

Fig. 2

hr. The pattern of fine lines seen in Fig. 1 might be interpreted in two ways. It might be the result of dislocations produced by the added barium chloride, a minimum concentration being necessary and a too high concentration resulting in such extensive disorganization of the lattice that no simple pattern is formed or can be discerned. Or, the pattern may be already present in the 'pure' crystal in the form of invisible internal surfaces or lines and is revealed by precipitation on these surfaces or lines of an added substance such as barium chloride when this is present within certain limits of concentration. High concentration of barium chloride produces a cloudiness which can be cleared again by heating. It is not possible from the present observations to decide between the two possibilities, but it seems that the incorporation of a suitable impurity in single crystals of alkali halides reveals a defect structure which might be used in the study of the formation and behaviour of such structures and the part they play in the behaviour of crystals under various conditions.

RADIATION CHEMISTRY

Polymer Formation in Irradiated *p*-Xylene

INVESTIGATIONS of the radiochemical behaviour of alkylbenzenes have predominantly been focused on the gaseous decomposition products, and data about the liquid reaction products are rather scarce.

As part of a study of the kinetics of radiolysis of alkylbenzene mixtures, *p*-xylene was submitted to mixed atomic pile radiation.

In view of the complex nature of mixed atomic pile radiation, a direct determination of the amount of energy absorbed by the sample is not always possible. For the work reported here it was chosen to use biphenyl as a reference component.

Biphenyl has been extensively studied in relation to its use as a moderator, and by choosing it as an irradiation standard it is expected to make possible a direct comparison of the data obtained on the lighter alkylbenzenes with the data which have already been accumulated for heavier products such as the terphenyls.

In addition to samples of pure *p*-xylene and biphenyl a certain number of mixtures of *p*-xylene and biphenyl were irradiated and analysed. The *p*-xylene and biphenyl both had a purity of 99 + per cent.

4-gm. samples of *p*-xylene, biphenyl or a mixture of both were sealed under vacuum in silica capsules (diam. 2 cm., height 6 cm.). Each capsule was placed in a tightly fitting aluminium container and irradiated in the *Y*7 channel of the *BR* I reactor at Mol, Belgium. The equilibrium temperature of the samples during irradiation was approximately 95° C.

After irradiation the liquid phase was analysed by gas-liquid partition chromatography using a 5-m. stainless steel column (1/4 in.) packed with 30/50 mesh 'Sil-O-Cel', impregnated with 30 per cent 'D–C' high-vacuum silicone grease. Helium at a rate of 100 ml./min. was used as a carrier gas and column temperature was stabilized at 150° C. The retention time of biphenyl was about 1 hr.

For quantitative analysis of the liquid-phase naphthalene was used as a tracer, and benzene as a solvent. The area correction factors were determined with solutions of known composition at the different concentration-levels encountered.

From the measured ratio of *p*-xylene or biphenyl to naphthalene and the known ratio of naphthalene to total sample, one derives the concentration of *p*-xylene or biphenyl in the sample. In order to investigate further the nature of the polymer formed, a fraction of the irradiated sample was distilled for 1 hr. at 150° C. under a pressure of 0·05 mm. mercury, yielding a colourless distillate and a gummy brownish residue of heavy polymer tar.

The concentration of *p*-xylene or biphenyl in the distillate was determined by the same analytical technique.

From the concentration of *p*-xylene in the sample before irradiation, after irradiation, and in the distillate one calculates the amount of *p*-xylene which has disappeared by radiolysis, as well as the amount of polymer formed, which can be differentiated in compounds of the boiling range of terphenyl and heavy polymer tar.

No correction was made to account for the gaseous decomposition products, as it was found that their weight was well below 1 per cent of the total sample weight.

Furthermore, a preliminary analysis showed that the amount of liquid products of lower molecular weight formed upon irradiation was so small that it has also been neglected in the material balance calculations.

The results have therefore been treated as if the disappearance of the initial compound measures the formation of products of higher molecular weight.

Typical experimental results on *p*-xylene and biphenyl are summarized in Table 1.

Table 1. TOTAL INCIDENT DOSAGE: 1·21 × 10^{19} nVT (THERMAL)

Weight (per cent)	*p*-Xylene	Biphenyl
Unchanged after irradiation	92	91
Total polymer	8	9
Heavy tar	2	7

From the results obtained at an incident dosage of $1 \cdot 21 \times 10^{18}$ nVt (thermal) (Table 1) and those obtained at $0 \cdot 76 \times 10^{18}$ nVt (thermal) it follows that *p*-xylene polymerizes according to the same rate law as biphenyl, which means that the reaction is a first-order process[1].

Mixtures of *p*-xylene and biphenyl varying in composition from 4·75 to 28·5 per cent weight of *p*-xylene were irradiated under the same conditions. The experimental results show that within the limit of accuracy of the analytical method the first-order rate law also applies. The results for heavy tar formation are not so conclusive as those concerning the *p*-xylene/biphenyl ratio. The rather large scatter of the results about heavy tar content versus *p*-xylene/biphenyl ratio may be attributed to the limitations of the analytical method used. The general trend of the results is, however, in agreement with a first-order rate law.

From the similarity of behaviour of *p*-xylene and biphenyl under the influence of mixed pile radiation one may also expect a similar behaviour with respect to gamma irradiation. As regards the radiochemical polymerization yield $G_p = \frac{\text{molecules polymerized}}{100 \text{ eV.}}$ of *p*-xylene, its magnitude may be taken as approximately 1·45 times the corresponding value for biphenyl.

A more detailed account will be published elsewhere.

I am indebted to Dr. F. Dupire for his advice about the chromatographic technique and to M. A. de Wilde for his interest in this subject.

Use of Ionizing Radiation in Spot Tests for Nitrogenous Compounds

SEVERAL spot tests are available for determining substances containing nitrogen, and are widely used in qualitative and semi-quantitative analysis[1]. All these involve the development of colour or fluorescence by spraying with suitable reagents. We have discovered that many nitrogenous compounds give a brown colour when spotted on to filter paper and exposed to doses of ionizing radiation in the range 5×10^{6}–2×10^{8} rads.

The results described below stem from an observation by one of us that ammonium dihydrogen phosphate spotted on filter paper and exposed to a flux of 10^{11} neutrons/cm.^{2}/sec. in the reactor *Bepo* for six days developed a brown colour. In subsequent work we used a 4-MeV. linear accelerator as a radiation source, since this could be used to deliver 10^8 rads in a much shorter time than the reactor and without inducing any radioactivity. Several different types of filter paper were tested and Whatman No. 4 selected as the most suitable: all papers became brittle and pale yellow after 10^8 rads, and cellulose acetate papers crumbled completely away after this treatment[2]. Colours developed slowly at room temperature and faster on warming. The best conditions for colour development were obtained using aliquots containing about 20 μgm. nitrogen exposed to 10^8 rads, when the limit of detection was approximately 2 μgm. nitrogen. Under these conditions well-defined brown spots were obtained from the following materials: ammonium chloride, methylamine hydrochloride, diethylamine hydrochloride, glycine, alanine, asparagine, proline, potassium nitrate, sodium nitrite and nitrobenzene. Fainter spots were obtained with acetamide, diphenylamine, pyridine and azobenzene, but no spots could be found when tetramethyl ammonium bromide and cetyl trimethyl ammonium bromide were tested. β-indolyl acetic acid gave a pink spot, while aspartic acid and trimethylamine hydrochloride were anomalous in giving deep brown spots on heating (with or without ionizing radiation).

The colour formation is probably due to a Maillaird reaction between amino-groups and aldehydic substances resulting from radiation-induced breakdown of cellulose. Presumably nitro groups are reduced to amino groups under these conditions of irradiation, and tertiary amines like pyridine undergo ring cleavage. However, no improvement in colour development could be obtained by soaking the filter paper in glucose solution before spotting and irradiating. As an analytical technique, the reaction is not so sensitive as the ninhydrin reaction for amino-acids, which can detect about 0·1 μgm. nitrogen, but it might be useful for detecting other substances which do not give the ninhydrin test. It has been used to develop paper chromatograms of amino-acids.

Finally, the reaction may be of interest to those concerned with radiation dosimetry. The fact that a colour will develop at 5×10^{6} rads, which is near the sterilizing dose for food and pharmaceutical materials, is important in this connexion.

Radiation Synthesis of Urea

LOISELEUR and PETIT[1] have reported that urea is formed in the X-irradiation of an ammoniacal and methanolic solution of *m*-phenylenediamine and dichloromethane in the presence of air. A further report has been given recently by Loiseleur, Petit and Clémentin[2] on the effect of oxygen-acceptors on the yield of urea. We set out to synthesize substituted ureas and to study the proposed mechanisms, but we found that no urea was formed in experiments with similar solutions.

γ-radiation from a cæsium-137 source (dose-rate: 10^{16} eV./ml./min.), taking $G_{Fe^{3+}} = 15 \cdot 5$, and X-rays from a copper target at 40 kV. and 20 m.amp. (dose rate: $1 \cdot 5 \times 10^{15}$ eV./ml./min.) were used in the experiments. Closed glass irradiation cells of 25 ml. capacity were fitted with polythene capillary tubing through which air was bubbled, after it had first passed through a vessel containing the solution to be irradiated. The solution (32 ml. methanol, 4 ml. dichloromethane, 250 mgm. *m*-phenylenediamine, 0·25 ml. 30 per cent aq. ammonia) was freshly prepared for each experiment. Reagents were carefully purified: methanol and dichloromethane were fractionated; ammonia (sp. grav. = 0·880) was diluted with distilled water; *m*-phenylenediamine was twice distilled under nitrogen and used immediately after the second distillation as well-defined light-yellow crystals (m.p. 61° C.) and xanthydrol was synthesized and used as a 10 per cent solution in ethanol[3]. After receiving total absorbed doses of γ-radiation ranging from 6×10^{17} eV./ml. to 7×10^{18} eV./ml. and of X-rays at $4{\cdot}5 \times 10^{16}$ eV./ml., the solutions were analysed for urea using Fosse's method with the xanthydrol reagent. This is the method used by Loiseleur and it might be noted that it is not specific for urea although a well-defined dixanthyl urea compound is formed[4]. (The reaction was erratic and even failed to proceed with quite large amounts of added urea when the reagent was used in the normal way.)

In all experiments where the xanthydrol reaction was used, whether the solutions were irradiated or not, well-defined white crystals were obtained in reasonable yield. Infra-red absorption spectra and elemental analysis showed quite clearly that the compound was not dixanthylurea. The empirical formula was $C_{6\cdot7}H_{4\cdot9}N_{0\cdot26}O_{0\cdot61}$.

A paper chromatographic method was therefore developed to detect urea. Various methods are available for the detection of as little as 10γ of urea[5]. However, the uni-dimensional technique with numerous solvents failed to distinguish urea satisfactorily from the more reactive *m*-phenylenediamine. The two-dimensional technique with butanol/ethanol/water (4 : 1 : 1) was adequate for more than 50γ urea. Aqueous pyridine (4 : 1) was found to allow good separations using the uni-dimensional ascending technique. The chromogenic reagent was 1 per cent dimethylaminobenzaldehyde in ethanol containing 1 ml. concentrated hydrochloric acid. After spraying, the chromatogram was heated at 100° C. for 5 min. to increase the intensity of the yellow urea spot. The limiting sensitivity of the method was 10–20 μgm. of urea in 1,400 μgm. of *m*-phenylenediamine.

Analyses by paper chromatography of aerated solutions, which were irradiated as described above, showed no trace of urea. For comparison, the lowest urea yield reported by Loiseleur and Petit (350 mgm. urea derivative per 100 ml. after an estimated $0{\cdot}75 \times 10^{6}$ r. of X-rays) is well within the limits of detection by chromatography. Our conclusion from these preliminary experiments, which were arranged to reproduce the conditions reported as closely as possible, is that no urea is synthesized by γ- and X-radiation of the 'Loiseleur' solution, or that the synthesis is extremely sensitive to dose-rate.

CHEMISTRY

Overturning of Stearic Acid Molecules in Monolayers

I have recently reported some experiments on the exchange of stearic acid molecules and potassium ions between mica surfaces brought into contact, and emphasized the importance of these phenomena in lubrication[1]. I wish now to describe some further results of these experiments, and discuss their significance in terms of the motions which long-chain polar molecules in mono-molecular layers on solid surfaces may undergo.

Rideal and Tadayon[2] first reported radiometric observations on the transfer of stearic acid–carbon-14 from monolayers deposited on solid surfaces to other solids brought into contact with them. Their experiments were carried out with metal-coated mica sheets as substrates, and no measurements of the area of contact were made, although it was suggested that it was only a small fraction of the total area of the sheets. After long periods (20–100 hr.) of contact, an apparent equilibrium in the amount transferred was reached. In Table 1, their results are summarized in terms of the surface from which the stearic acid was removed.

Table 1. 'Equilibrium' Transfer of Stearic Acid; 36° C. (Rideal and Tadayon)

From	To	Amount (per cent)
Mica	Mica	50–60
	Tin	85
	Platinum	90
Tin	Tin	50
	Nickel	65
	Copper	85
	Silver	80
Silver	Silver	45
	Copper	80
	Tin	65
	Platinum	90
Copper	Copper	4
	Silver	4
	Tin	6
	Platinum	8
Nickel	Nickel	6
	Tin	8
	Copper	10
Platinum	Silver	15
	Copper	8

As shown in Table 1, the substrates used fall into two groups: those which can give up a major fraction of the stearic acid (mica, tin, silver) are relatively inert to reaction with the fatty acid, while those which lose only a few per cent of the acid initially present (copper, nickel) are reactive metals. (Platinum seems to be somewhat anomalous; as Young[3] has suggested, this may reflect a strong physical interaction due to the thinness or absence of an oxide film on platinum.)

In the previous report[1], it was shown that the extent of transfer of a stearic acid monolayer between two mica sheets brought into contact for even a few minutes was about half that present in the area of contact. It was also found that potassium ions from the exchangeable-ion sites on the mica surfaces were exchanged, even in the presence of the stearic acid monolayer. Two other cases have now been examined qualitatively. Transfer between two monolayers of stearic acid has been observed, using one radioactive and another non-radioactive stearic acid film, both deposited on mica. Some observations of transfer from barium stearate monolayers (stearic acid spread on solution 10^{-4} *M* barium chloride and 10^{-3} *M* in potassium bicarbonate, adjusted to *p*H 9 with potassium hydroxide) on mica have also been made. In the present measurements, the technique of Rideal and Tadayon was used. The possibility of vapour-phase transport in these systems was also examined. Young[3] had observed such transport at elevated

Table 2. OBSERVED COUNT RATES (PER CM.^{2}) ON MICA SHEETS IN CONTACT AND TRANSFER EXPERIMENTS (EACH 5–10 MIN.)
(Corrected for background count)

	Radioactive sheet		Inactive sheet
	Initial	Final	
Stearic acid monolayers :			
Separated 1 mm., air	650 c./m.	650 c./m.	0 c./m.
Separated 1 mm., p = 50μ	650	450	75–150
Contact	650	—	uncoated 18–40 stearic acid monolayer 5–15
Barium stearate monolayers :			
Separated 1 mm., p = 50μ	650 c./m.	620 c./m.	—
Contact	650	—	42 c./m. (uncoated)

temperatures, and suggested that it might account for the apparent diffusion described by Rideal and Tadayon. The present experiments were carried out at room temperature (25 ± 2° C.).

The experimental results are shown in Table 2, where count-rates observed with an end-window Geiger–Müller counter placed over the sample after the indicated exposure are listed. For the measurement of initial rates, and for the samples exposed without contact, a mask was used and an area of 1 cm.^{2} near the centre of the sheet was examined. The samples in contact, as might be expected, showed wide variations in activity over their surfaces. The values given for them represent the count-rate of the whole sheet (observed without a mask) divided by the sheet area to give the average count-rate for 1 cm.^{2}.

As indicated in Table 2, exposure of two sheets of mica 1 mm. apart in room air shows no significant transfer after 5–10 min. After 1 hr. of such exposure, the result is the same. However, when the samples are placed in a vacuum chamber and the pressure is reduced to 50μ for 5 min., almost one-third of the activity of the radio-stearic acid monolayer is lost, and a comparable amount is found on the initially inactive sheet. With barium stearate, however, the loss of activity is much less. In contact experiments, however, no such difference appears ; transfer of barium stearate and stearic acid to fresh mica surfaces is of the same order of magnitude. When a stearic acid monolayer is confronted not with a clean mica surface, but with one which is coated with another stearic acid monolayer, transfer (exchange ?) also occurs. It seems that the amount transferred is less in the latter case, although the possible variation in true contact area in these experiments prevents any definite statement on this point.

The results are in good agreement with the observations of Young on stearic acid and stearate monolayers, and support his suggestion of vapour-phase transport in the work of Rideal and Tadayon. If we consider all these results in the framework of Langmuir's mechanism for the overturning of stearate molecules in monolayers[4], correlations are obvious. The molecules in the monolayer are held in their 'normal' (polar head toward the substrate) position if there is a strong interaction between the polar head and the underlying material. This can be a chemical bond or perhaps a strong physical interaction such as that between stearates and platinum. This accounts for the strong attachment, lack of reduction of contact angle in the presence of water and lack of vapour-phase transfer with monolayers on reactive solids.

If a stearic acid monolayer is deposited on an unreactive substrate, some of the molecules may at any time be overturned. Whenever there is a possibility of anchoring these molecules in the overturned position (another surface brought into contact or a liquid water drop placed on the surface), such a process will proceed to an equilibrium determined by the minimization of the energy of the system. Analogous behaviour will be found with soap monolayers. It now appears probable that the transfer of potassium ions observed in my previous work[1] is to be associated with soap formation.

Differences should, however, be expected in the vaporization behaviour of divalent soap and free-acid monolayers on unreactive solids. The energy required to separate a barium stearate molecule from its neighbours will obviously be greater than that required to remove a single stearic acid molecule, on the basis of chain–chain interactions. This is in agreement with the experimental results.

From the point of view of lubrication phenomena, of course, it is necessary to consider liquid systems and adsorbed polar films. Studies of how the presence of bulk liquid will affect the processes described above are now in progress.

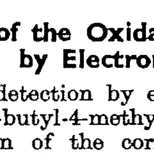
Study of the Oxidation of Hindered Phenols by Electron Spin Resonance

THE detection by electron spin resonance of the 2,6,-di-t-butyl-4-methylphenoxy radical during the oxidation of the corresponding phenol with lead dioxide has been reported recently[1]. The purpose of this communication is to report a similar investigation of the free radicals formed during the oxidation of solutions of the hindered phenols 2,6,-di-t-butyl-4-R-phenol [where $R \equiv$ methyl (I) ; ethyl (II) ; and t-butyl (III)] with an alkaline solution of potassium ferricyanide.

This method of oxidation has the advantage that only the phenoxy radicals are formed, whereas in the former case secondary radicals were soon observed. Furthermore, the hydrocarbon solution of the radical can be rapidly separated from the oxidizing medium, which permits the kinetics of radical decay to be determined.

Both the methyl and ethyl phenols, (I) and (II), give transient electron spin resonance spectra which are attributed to the corresponding phenoxy radicals, (IV) and (V). The t-butyl phenol (III) gives the spectrum due to the stable phenoxy radical (VI)[2].



R ≡ methyl (IV)
ethyl (V)
t-butyl (VI)

The spectrum from the methyl phenoxy (IV) consists of four triplets. This is identical with the spectrum already reported[1]. The spectrum of the ethylphenoxy (V) consists of three triplets, and is attributed to the interaction of the unpaired electron with the two —CH_2— protons of the ethyl group (major splitting) together with a much smaller interaction with the two ring protons. The interaction

Table 1. HYPERFINE SPLITTING CONSTANTS OF 2,6-DI-*t*-BUTYL-4-*R*-PHENOXY RADICALS

Para-substituent *R*	Hyperfine splitting (oersted)	
	Para-alkyl protons	Ring protons
Methyl	11·0 ± 0 1	1·65 ± 0 05
Ethyl —CH_2—	8·65 ± 0·1	1 70 ± 0·05
Ethyl —CH_3	not resolved	
t-Butyl	not resolved	1·84 ± 0·05

with the —CH_3 protons of the ethyl group is too small to give a resolvable splitting of the spectrum. This is in line with the fact that the protons of the para *t*-butyl group of the butyl-phenoxy (VI) do not give a resolvable splitting. The hyperfine splitting constants of the electron spin resonance spectra are summarized in Table 1.

The assignment of the electron spin resonance spectra to the phenoxy radicals is confirmed by the fact that all three spectra can be interpreted logically on the same basis.

The oxidation of the methyl phenol (I) yields appreciable amounts of the following dimers: 1,2-*bis*(3,5-di-*t*-butyl-4-hydroxyphenyl) ethane and 3,5,3',5'-tetra-*t*-butylstilbene-4,4'-quinone, which suggests that the initial oxidation occurs on the methyl group to give the 4-hydroxy-3,5,-di-*t*-butylbenzyl radical. However, Cook *et al.*[3] have suggested that the following sequence of reactions occurs during the oxidation:

$$\text{phenol} \xrightarrow[\text{[O]}]{} \text{phenoxy} \xrightarrow[\text{[rearrangement]}]{} \text{benzyl} \xrightarrow[\text{[dimerization]}]{} \text{end products} \quad (1)$$

Becconsall *et al.*[1] have confirmed that the phenoxy radical (IV) is formed during the oxidation, but suggest that the next step is the formation of a complex between two phenoxy radicals, rather than a re-arrangement to the benzyl radical. There is also the possibility that the phenoxy radical decays by the reaction:

$$\text{phenoxy} + \text{phenol} \longrightarrow \text{phenol} + \text{benzyl} \quad (2)$$

The present results show that the methyl phenoxy (IV) decays with first-order kinetics, and that the rate of decay is independent of the concentration (0·1–5 per cent) of the parent phenol (I) initially present. However, the rate of decay is influenced by the solvent, and is slower in a highly polar solvent; for example, the rate constants in benzene, methyl*cyclo*hexane and acetone at 25° C. are $1 \cdot 33 \times 10^{-2}$ sec.$^{-1}$, $1 \cdot 23 \times 10^{-2}$ sec.$^{-1}$ and $0 \cdot 35 \times 10^{-2}$ sec.$^{-1}$ respectively. In methyl*cyclo*hexane the decay process has an activation energy of 11·4 kcal./mole and a frequency factor of $3 \cdot 1 \times 10^{6}$ sec.$^{-1}$.

These kinetic results show that the phenoxy radical does not decay according to equation (2), since such a reaction would follow second-order kinetics. Furthermore, the first-order kinetics are consistent with the decay being due to an intramolecular rearrangement rather than dimerization or complex formation, which would follow second-order kinetics.

The suggestion that two phenoxy radicals form a complex before rearranging is based on the fact that the cross-products, from the reaction between phenoxy and benzyl radicals, are not formed in appreciable quantities. However, recent results suggest that the *t*-butyl-phenoxy (VI) reacts surprisingly slowly with various other free radicals[4]. Thus it is quite possible that the cross-reactions in the case of the methyl phenoxy (IV) only occur slowly.

The frequency factor is very low for a unimolecular reaction. Dewar[5] has suggested that during an intramolecular rearrangement the migrating group forms a π-complex with the ring, and that bulky substituents on the ring will reduce the rate of rearrangement. In addition, since a free radical possesses an excess electron, it will only form a π-complex with difficulty and thus be rearranged only slowly. Both these effects may be the cause of the low rate of rearrangement found for the methyl phenoxy (IV).

The ethyl phenoxy (V) also decays with first-order kinetics, but at a slower rate than the methyl phenoxy (IV); for example, the rate constant in benzene at 25° C. is $0 \cdot 75 \times 10^{-2}$ sec.$^{-1}$. The first-order kinetics for the ethyl phenoxy (V) show that this also decays by a rearrangement reaction. This is in contrast to the *iso*propylphenoxy ($R \equiv$ *iso*propyl), which decays by a radical–radical reaction, giving second-order kinetics[6].

I wish to thank the directors of "Shell" Research, Ltd., for permission to publish this communication, Mr. J. H. T. Brook and Dr. R. L. Allen for helpful discussion, and Mr. E. J. H. Morgan for assistance in the experimental work.

Decomposition of Methyl Acetylene

METHYL ACETYLENE (propyne) is akin to acetylene in being an endothermic compound the induced decomposition of which will support a flame in the absence of air. The work now reported and a parallel investigation[1] have shown that as in the case of acetylene there is a critical pressure below which a flame is not propagated in pure propyne vapour. This low-pressure limit of propagation has been determined in a cylindrical vessel of internal dimensions 2 in. diameter by 7 in. long mounted vertically; the pressure of the vapour in the vessel was measured by means of a Bourdon gauge with a steel tube. A fuse-wire igniter supported on the vertical axis near the bottom of the chamber was used to ignite the vapour; the wire, a 1-in. length of 0·0135 in. diameter tinned copper, was energized by a 12 volt a.c. supply. Determinations were made at approximately 20° C. and at 120° C. by increasing the pressure of propyne vapour in the vessel until propagation occurred (indicated by a pressure rise) when the igniter was fired.

Dilution tests have been made in the same apparatus, which was then contained in a heated cabinet maintained at 120° C. to prevent condensation of the propyne vapour at the pressures used. Propyne vapour was mixed with nitrogen, methane and ethane respectively; the composition of the mixtures was

Table 1

Temp. (° C.)	Values of low-pressure limit (p.s.i.g.)	Initial total pressure (p.s.i g.)	Percentage by volume of diluent required to render mixture non-explosible		
			Nitrogen	Methane	Ethane
Approx. 20	50				
120	31				
		100	30	26	15
		200	45	37	23
		300	55	41	26

determined from measurements of the partial pressures of the constituents in the apparatus and checks were made by analysis using a mass-spectrometer. The minimum amount of each diluent required to prevent flame propagation in the mixture at total pressures of 100, 200 and 300 pounds per square inch (gauge) was determined.

The results of the determinations are shown in Table 1.

At the low-pressure limit the dissipation of heat from the flame is so disproportionately large compared with the heat release by reaction that the flame temperature is reduced to a point where the reaction cannot continue and extinction occurs. The heat is dissipated as radiant losses, in heating the combustion products of the flame and any diluents in the flame, and possibly by thermal cracking of the diluents. Thus diluting the flame increases the quantity of heat dissipated within it and limits can occur above the low-pressure limit for pure propyne.

As might be expected from the presence of the methyl group attached to the acetylene molecule the value of the low-pressure limit of propyne is higher than that reported for acetylene in a vessel of the same diameter[2]. An increase of the temperature of the system causes a decrease in the lower limit of flame propagation for propyne, presumably by decreasing the radiation loss from the flame front to the container walls and also by increasing the available enthalpy in the system. When the values of the low-pressure limit from this and a parallel investigation[1] are plotted versus diameter of vessel in which the determinations were made, a graph of the same form as that reported for acetylene is obtained, though the minimum decomposition pressure range reported for acetylene and some substituted acetylenes[2] has not been investigated in this work.

As an inhibitor of the decomposition flame nitrogen is the least efficient of the diluents used, followed by methane and then ethane. This is the order expected on the basis of the combined effect of the molar heat capacities and readiness to decompose with absorption of heat. Thus the hydrocarbons are the more efficient as they have higher specific heats than nitrogen and they absorb heat on cracking; ethane is more efficient than methane as it is less thermally stable[3]. This result is in agreement with previous work[4] where dilution tests were made with acetylene mixtures at total pressures up to 100 pounds per square inch (gauge), which showed that the efficiency of hydrocarbons in inhibiting the reaction increased with increasing molecular weight, and to a much lesser extent with decreasing thermal conductivity. The result is also in agreement with other results for acetylene decomposition at pressures up to 300 pounds per square inch (gauge), where methane appears to be a more efficient inhibitor than nitrogen; no explanation of the results is offered by the authors[5].

The products of the decomposition of propyne are soot and gases. Mass-spectrographic analysis of the cooled gases from both pure and diluted propyne showed them to be hydrogen and methane (the latter up to 30 per cent of the total volume), though unreacted propyne and traces of ethylene and acetylene were found and the diluents from the mixtures. No 'fixing' of the nitrogen as hydrocyanic acid or ammonia previously reported for acetylene and nitrogen mixtures[6] was noted. It is believed that this is because of the low temperature of the reaction (approximately 1,550° C. theoretical temperature for the reaction $C_3H_4 = 3C_{(s)} + 2H_2$, and probably much less than this due to radiation loss from the flame); previous work[7] indicates that free carbon must be available at temperatures above 1,700° C. in the presence of nitrogen and hydrogen in order for hydrocyanic acid to be formed.

The propyne used was approximately 98 per cent pure, the main impurity being the isomer allene.

The work was carried out at the Rocket Propulsion Establishment, Westcott, Bucks. The help and guidance given by Dr. A. R. Hall during the course of the work are gratefully acknowledged; the gas analyses were made by Dr. G. A. Heath.

Alkylation of Coal by Benzyl Chloride-Aluminium Chloride

ALTHOUGH several reports have recently been made[1] on the carbonization of model substances synthesized to imitate the structure of coal, the study of coal pyrolysis has been hampered due to lack of knowledge of the pattern of behaviour of the functional groups. It was therefore decided to alkylate coals with alkylating agents of known structure and study their behaviour on carbonization. This seems to be the first time that alkylation of coal has been reported.

Coal (25 gm.) suspended in carbon disulphide (40 ml.) was heated with benzyl chloride (10 ml.) in the presence of anhydrous aluminium chloride (3 gm.) at 90–100° C. for 2 hr. Under similar conditions benzene is known to be alkylated to diphenyl methane[2]. The product was then hydrolysed by hydrochloric acid and filtered. The residue was repeatedly washed with distilled water until free of acid, and then dried in a vacuum oven.

Elementary analyses of the coals and products are given in Table 1. With the exception of lignite, the coals show an increase in the content of volatile matter. Similarly, except for the high-rank Albion, Jharia and Bhulan Bararee coals, all the coals show an increase in their carbon content. The ratio hydrogen/carbon changes erratically—in some cases increasing, in others decreasing, and in others not showing any change.

Table 1. ALKYLATION OF COAL BY BENZYL CHLORIDE–ALUMINIUM CHLORIDE

Coal	Elementary analysis of original coal (dry mineral-free basis per cent)							Elementary analysis of alkylated coal (dry mineral-free basis per cent)

Table 2. LOW-TEMPERATURE CARBONIZATION OF ALKYLATED COAL

Coal	Original coal (dry mineral-free basis per cent)				Alkylated coal (dry mineral-free basis per cent)			
	Coke	Tar	Liquor	Gas	Coke	Tar	Liquor	Gas
1	42·2	13·4	28·1	17,375	61·2	19·1	6·7	12,120
2	70·5	13·0	6·7	—	60·3	25·3	6·6	10,310
3	72·8	8·3	7·1	11,320	65·8	16·3	10·8	8,970
4	73·0	12·4	8·5	10,670	68·0	19·3	5·0	9,390
5	79·3	8·4	4·6	11,200	71·0	15·0	6·6	7,250
6	80·2	7·3	3·2	9,930	74·6	15·8	—	9,930

A careful study of the ratio hydrogen/carbon in alkylated models of polycondensed aromatic systems shows that it depends on the number of aromatic rings present in the system. For example, benzene, naphthalene, and pyrene exhibit a decrease in the ratios hydrogen/carbon on alkylation, whereas a 10-membered system indicates an increase in the hydrogen/carbon ratio on alkylation. But in the case of coal, it is not clear whether or not the variation in the hydrogen/carbon ratio is attributable to the number of rings in the aromatic system. X-ray results with treated coals have indicated marked variation in the size and distribution of the aromatic nucleus compared to original coals (Ali, S. Z., private communications).

The most significant changes are in the carbonization assays (Table 2). In all cases there is considerable increase in the yield of tar, which is nearly doubled. Except for lignite, the coals show a decrease in the coke yield. In the case of lignite there is a marked decrease in the liquor yield and also in the coke yield. But in the other cases there is no regularity about the variation in the liquor. There is also a deterioration in the quality of coke. For example, Bhulan Bararee coal gave originally a G_1 type coke, but after treatment only a C type coke. In all cases there is a decrease in yield of gas.

There is no doubt that coal reacts with benzyl chloride and that this reaction considerably influences the yield of tar, and the quality of coke. A detailed consideration of the structural changes on alkylation and the changes on carbonization will be published later.

Acidic Dissociation Constant of Alcoholic Hydroxyls of Oxycarboxylic Acids: Mandelic Acid

THE oxycarboxylic acids are very strong complex-forming agents, and both the carboxylic and the alcoholic hydroxyl groups take part in such formation. For calculation of complex stability constants it is necessary to know the acidic dissociation constants of both groups. However, the alcoholic hydroxyls are so weakly acidic that it is not possible to determine the dissociation constant by the usual methods. So far as we know, until now none of the oxycarboxylic acids has been investigated successfully from the point of view of acidity of alcoholic hydroxyls. The only data which we found referred to citric acid; however, these were theoretical values[1].

In general, the oxycarboxylic acids show no absorption even in the extreme ultra-violet regions. An exception is the absorption of mandelic acid, which, due to the benzene ring, is fairly high in the ultra-violet region. However, absorptions of mandelic acid and the mandelate ion do not differ from each other. We determined the change of absorbancy at very high *p*H, that is to say, in strongly alkaline solution.

The mandelic acid shows a maximum absorption at 264 mμ and a minimum at 244 mμ. The effect of ionizing the carboxyl group is to increase the maximum to 260 mμ; however, the minimum does not change. The effect of greater alkali concentration (increasing ionization of alcoholic hydroxyl) causes both the maximum and the minimum to disappear; the absorption monotonously increases with decreasing wave-length.

To calculate the dissociation constant we assumed that the only reason for the change in absorption on treatment with sodium hydroxide is the gradual ionization of alcoholic hydroxyl. Table 1 shows the change of absorption at 244 mμ as a function of *p*H. We used the *p*H values determined by Schwarzenbach and Sulzberger[2] instead of sodium hydroxide concentration. The absorption does not reach a limiting value due to the equilibrium:

$$\mathrm{C_6H_5}\underset{\mathrm{OH}}{\mathrm{CH}}\mathrm{\cdot COO^-} \rightleftharpoons \mathrm{C_6H_5\cdot}\underset{\mathrm{O^-}}{\mathrm{CH}}\mathrm{\cdot COO^-} + \mathrm{H^+}$$

(I) (II)

being shifted so far to the right even at maximal sodium hydroxide concentration that practically all the mandelic acid is in the form of ion II. Thus the molar absorption of II cannot be calculated directly and hence we calculated it by Stearns and Wheland's method[3]. The molar absorption of I at 244 mμ is 120·5, while that of II is 719 at the same wave-length. Using these values the concentrations of I and II in the dissociation constant:

$$K = \frac{[\mathrm{II}]\ [\mathrm{H^+}]}{[\mathrm{I}]}$$

can be calculated. The values of K are given in the fourth column of Table 1, its average being 7·19 × 10^{-16}.

Table 1

[NaOH]	pH	A_{244}	$K \times 10^{16}$
—	4	0·250	—
—	10	0·236	—
0 279	13·3	0 250	6·75
1·395	14·1	0·344	8 24
2·79	14·5	0·477	8·29
5·58	15·2	0·747	4·45
10·16	16 2	1 815	7·96
		Average	7·19

Details of this research will be published in full elsewhere. Thanks are due to Dr. J. Császár for the measurements of absorption.

BIOCHEMISTRY

Structure of Bhilawanol

Bhilawanol is the golden yellow liquid found in the pericarp of the marking nut *Semecarpus anacardium*. It forms a di-naphthylurethane and a dimethyl ether and on catalytic reduction it absorbs one mole of hydrogen to give hydrourushiol (3-pentadecylcatechol)[1,2].

Ozonolysis of the diphenylmethylene ether gave heptaldehyde[2] (in low yield), suggesting that at least a portion of the bhilawanol is 3-(pentadecenyl-8′)-catechol (thus corresponding to the urushenol of poison ivy and Japanese lac[3]).

Although distillation of dimethyl bhilawanol[1] and chromatography of the diphenylmethylene ether[2] pointed to bhilawanol as being a single substance, chromatography of the dimethyl bhilawanol using the procedure described by Symes and Dawson[4] showed that it was not homogeneous (Symes, W. F., unpublished work). Furthermore, the glycol, m.p. 56–60°, prepared by performic acid hydroxylation of distilled dimethyl bhilawanol, on chromatographing, separated into two glycols, one melting at 66·8°, the other at 93–4° (Symes, W. F., unpublished work).

The low-melting isomer is identical to the glycol prepared by performic acid (*trans*) hydroxylation of the dimethyl ether of the stereochemically pure *cis* poison ivy urushenol[4]. The high-melting isomer is identical to the glycol prepared by osmium tetraoxide (*cis*) hydroxylation of this same material[3]. It therefore becomes clear that the bhilawanol is a mixture of the *cis* and *trans* isomers of urushenol.

These conclusions are evident from Table 1.

Table 1

Compound	n_D^{25}	m.p.	Dimethyl ether		Di-naphthyl-urethan, m.p.
			n_D^{25}	Glycol, m.p.	
Bhilawanol*	1 5032 (ref. 1)	15°	1 5000	67 and 93†	138–40° (ref. 1)
Urushenol (*cis*)‡	1 5081	33°	1 4945	95† 67§	139–41° (ref. 3)
Urushenol (*cis–trans*) (ref. 3)	1 4970	10–15°		92° and lower melting solid†	137–39° (ref. 3)

* Distilled but not chromatographed; † performic acid hydroxylation; ‡ synthetic (ref. 3); § osmium tetraoxide hydroxylation.

The melting ranges of the solid derivative, the dinaphthyl urethane, is evidently a poor criterion of homogeneity in this series.

Bhilawanol and the *cis–trans* urushenol prepared by acid catalysed isomerization of *cis* urushenol[3] are very similar, and there can be little doubt that bhilawanol contains a component identical to the monolefinic component of poison ivy urushenol.

Age Difference in Nicotinamide Mononucleotide Synthesis by Human Erythrocytes

It is well known that human erythrocytes contain an active enzyme system capable of synthesizing considerable amounts of nicotinamide mononucleotide from nicotinamide added *in vitro*[1]. The nicotinamide mononucleotide synthetase is very specific for human erythrocytes as the only other mammal in the blood cells of which it could be detected is the guinea pig[2]. It was found here, however, that the activity of the given synthetase in human erythrocytes can be shown at the beginning of the fifth month of life when its activity rapidly reaches almost a maximum level, remaining then practically without change. Whereas mammalian erythrocytes not synthesizing nicotinamide mononucleotide are characterized by a high content of pyridine nucleotides, their amount being several times higher than in human and guinea pig erythrocytes[2], the non-synthesizing child erythrocytes contain even somewhat less pyridine nucleotides than those of adult humans.

The amount of pyridine nucleotides and the nicotinamide mononucleotide synthetase activity were determined fluorometrically by a slightly modified method of Leder and Handler[1]. The nicotinamide mononucleotide synthetase activity was expressed as:

$$I_{20h} = \frac{b - a}{a}$$

where a is the concentration of pyridine coenzymes in µmoles/ml. erythrocyte mass before incubation and b the same after 20 hr. stationary incubation at 37° C. in Krebs–Ringer phosphate solution containing 250 mgm. per cent glucose and 2 per cent nicotinamide besides the mineral constituents. A total of 80 samples of heparinized blood from quite normal children and adults was examined. The results are shown in Fig. 1.

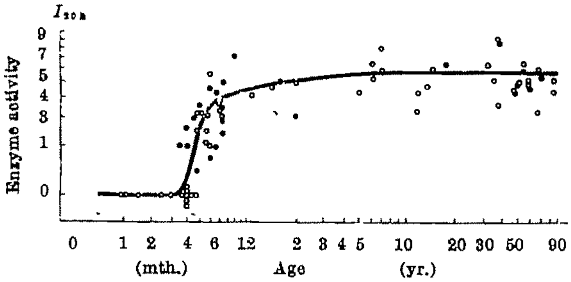

Fig. 1. Age difference in nicotinamide mononucleotide synthetase activity in human erythrocytes

The erythrocyte synthetase activity of adult humans under the given conditions amounts to 4·8 ± 1·3. Marked changes are observed in some diseases; for example, the activity is considerably decreased or completely lost in uræmia (a communication on this point will be presented later). The content of pyridine nucleotides in adult human erythrocytes is 0·11 ± 0·01 µmole/ml. erythrocyte mass, erythrocytes of infants before 4 months of age 0·09 ± 0·01 µmole/ml. The pyridine coenzyme-level of erythrocytes is very constant and is not affected by those factors which change markedly the nicotinamide mononucleotide synthetase activity *in vivo*.

The basis of inability of sucklings' erythrocytes to synthesize nicotinamide mononucleotide has not yet been elucidated. It is possible that erythrocytes produced in the course of the first months of life, when the synthesis of fœtal hæmoglobin regresses, are not mature in this respect; it cannot be excluded, however, that a specific or a non-specific inhibitor of the given synthetase was present.

However, the results present a further proof that human biochemical ontogenesis is not limited to the embryonic and fœtal period. Some metabolic systems develop and improve only after birth; the first months of life appear to be of exceptional importance in this respect.

We are grateful to Dr. M. Lukešová, Clinic of Pediatry, and to Dr. V. Čepelák, Medical University Clinic, for supplying us with the blood samples. We also wish to thank Miss E. Maidlová for technical assistance.

Microbiological 11β-Hydroxy Dehydrogenation of Corticosterone

A LARGE number of bacteria are known to dehydrogenate the secondary alcohol group of the steroid molecule, at carbon 3 and 17 [1], and also in position 7 and 12 [2].

However, dehydrogenation of the 11β-hydroxy group by micro-organisms has been reported in a few cases. For example, *Cunninghamella blakesleeana*[3] produced a certain amount of cortisone as a by-product of hydrocortisone from Reichstein's compound *S*, and *Trichothecium roseum*[4] produced a small amount of cortisone besides hydrocortisone from corticosterone. From these examples, it appears that 11β-hydroxy dehydrogenase, which has been known to be present in mammalian tissues, is also present in micro-organisms.

During our work on microbiological oxidation of steroids, we found the effective dehydrogenation of the 11β-hydroxy group of corticosterone by *Absidia regnieri*. In this case, introduction of a hydroxy group in the 14α position of the steroid molecule was caused by this micro-organism.

The present communication reports the effective dehydrogenation of the 11β-hydroxy group of corticosterone. In our experiment, *Absidia regnieri* was grown on a reciprocating shaker for 48 hr. at 27° in 5 l. of a medium of the following composition: 5 per cent glucose, 2 per cent peptone and 0·5 per cent corn steep liquor. Then 2·5 gm. corticosterone dissolved in methanol was added in this culture and fermentation was allowed to proceed for an additional 48 hr. At the end of fermentation, the culture was separated into mycelium and liquid, and these were extracted with ethyl acetate ester, respectively. The combined ethyl acetate ester extract was evaporated to dryness *in vacuo*. Paper partition chromatography of this residue showed only one oxygenated product and no unreacted steroid. The oxygenated product was isolated by direct crystallization or chromatography of 'Florisil'.

Crystallization of this residue with acetone afforded a 14α-hydroxy-11-dehydrocorticosterone (I); m.p. 205–215°; $[\alpha]_D + 69°$ (methanol); $\lambda_{\text{max.}}^{\text{MeOH}}$ 237·5 mµ (ε = 15,000); $\lambda_{\text{max.}}^{\text{KBr}}$ 3,480, 1,705, 1,660 and 1,620 cm.$^{-1}$; anal. found: C, 69·70; H, 7·78 per cent; calc.: C, 69·97; H, 7·83 per cent. 21-Monoacetate of I was prepared with pyridine and acetic anhydride; m.p. 204–5°; $\lambda_{\text{max.}}^{\text{MeOH}}$ 237 mµ (ε = 15,300); $\lambda_{\text{max.}}^{\text{KBr}}$ 3,560, 1,750, 1,735, 1,690 and 1,625 cm.$^{-1}$.

The structure of I was established in the following manner. When 11-dehydrocorticosterone was fermented with this fungus, the oxygenated product obtained was identical to I. This result and the observed ultra-violet maximum 237 mµ of I indicate that the 11β-hydroxy group of the steroid was converted to ketone. To decide the position of the new hydroxy group introduced, we have prepared new steroid 14α-hydroxy-corticosterone (II) by incubation of known 14α-hydroxy-deoxycorticosterone with *Stachylidium bicolar*, which is capable of 11β-hydroxylating of steroid. The compound II melted at 206–215°; $[\alpha]_D + 180°$ (methanol); $\lambda_{\text{max.}}^{\text{MeOH}}$ 241·5 mµ (ε = 16,500); $\lambda_{\text{max.}}^{\text{KBr}}$ 3,400, 1,710, 1,650 and 1,620 cm.$^{-1}$. The 21-acetate of II prepared with pyridine and acetic anhydride was oxidized with chromium trioxide-pyridine to 11-ketone. The material thus obtained agreed with the 21-monoacetate of I by physical constants and infra-red spectrum. This result indicates that the newly introduced hydroxy group must be 14α-hydroxyl.

From these results we conclude that the structure of I is 14α-hydroxy-11-dehydrocorticosterone. This fungus, however, had no effect on the conversion of epicorticosterone and hydrocortisone. This fact shows the marked stereospecificity of this dehydrogenase, that is, it acts only on 11β-hydroxyl of corticosterone and not on that of hydrocortisone or 11α-hydroxyl of epicorticosterone.

With the other steroid substrate, this fungus also showed remarkable substrate specificity as reported previously[5]. That is, it hydroxylated progesterone or deoxycorticosterone at the 14α-position and 17α-hydroxyprogesterone or Reichstein's compound *S* at the 11α-position.

Enhancement of Peroxidase Action by Polysaccharides

A NUMBER of polysaccharides act as polymerization-directing matrices in peroxidase-catalysed eugenol oxidations[1]. Although deoxyribonucleic acid and cellulose increase markedly the rate of Fe(III)-catalysed pyrogallol oxidation by hydrogen peroxide[2,3], a similar test of polysaccharides has not been reported previously in peroxidase-catalysed reactions.

The present results show that the catalytic activity of peroxidase is increased appreciably by moderately low concentrations of starch and is somewhat influenced by methylcellulose as well.

Oxidations were followed at 25° C. with the Bausch and Lomb 'Spectronic 20' spectrophotometer in 10-ml. reaction mixtures containing 5 μgm. Worthington horseradish peroxidase, 10^{-3} *M* hydrogen peroxide, substrate and *M*/20 phosphate buffer, *p*H 4·5. Oxidation of 5×10^{-3} *M* pyrogallol was measured at 425 mμ; oxidation of 5×10^{-4} *M* eugenol was measured at 360 mμ.

The chemical substances used were of reagent grade when possible. Methylcellulose solutions were prepared from 'Dow Methocel *HG* 400'. Neither starch nor methylcellulose exhibited catalytic activity when tested directly with hydrogen peroxide and pyrogallol.

In ten experiments, 5×10^{-5} *M* starch increased oxidation of pyrogallol by peroxidase appreciably (Table 1). The initial rate (0·5 min.) was most affected, but considerable enhancement is still in evidence after 2–3 min., when the control reaction-rate has slowed markedly.

Table 1. EFFECT OF STARCH ON PEROXIDASE-CATALYSED PYROGALLOL OXIDATION*

Reaction time (min.)	(*a*) Control Average optical density	σ	(*b*) Starch* Average optical density	σ	*b*/*a* (percentage control)

2 0	0·635	± 0·036	0·847	± 0·023	133
3·0	0·775	± 0·062	1·033	± 0·047	133

* Reaction mixture: 10 ml. *M*/20 phosphate, *p*H 4·5, containing 5×10^{-3} *M* pyrogallol, 10^{-3} *M* hydrogen peroxide, 5 μgm. peroxidase, with or without 5×10^{-5} *M* starch. Oxidation was carried out at 25° C. and measured at 425 mμ.

† Each figure is the mean of 10 determinations.

Stimulation is not limited to the oxidation of pyrogallol, but is also obtained with eugenol as substrate (Table 2*b*).

Table 2. EFFECT OF SEVERAL CARBOHYDRATES ON THE PEROXIDATION OF PYROGALLOL AND EUGENOL*

Carbohydrate	Concentration (*M*)	Effect (percentage control after 1 min.)
	(*a*) Substrate: pyrogallol	
Glucose	5×10^{-5}	100
	10^{-3}	99
	0·5	84
Maltose	5×10^{-5}	103
	10^{-3}	100
	0·5	86
Methylcellulose	5×10^{-5}	117
Starch	5×10^{-5}	147
	(*b*) Substrate: eugenol	
Glucose	0·5	83
Methylcellulose	5×10^{-4}	125
Starch	5×10^{-5}	143

* Reaction conditions as given in Table 1 except that eugenol was used at 5×10^{-4} *M* and its oxidation followed at 360 mμ.

Methylcellulose is not as stimulating as starch when tested with either substrate, but the activity of these two macromolecules may be contrasted with the effects of glucose and maltose (Table 2*a*, *b*). The simple sugars have no effect in low concentrations, and they are slightly inhibitory at high concentrations. A proper comparison between simple sugars and polysaccharides cannot be made on a mole-for-mole basis, nor can they be equated in a simple way by comparing the number of monosaccharide residues present.

A macromolecular basis for the stimulatory effects of polysaccharides is suggested by the absence of enhancement of sugars over a wide range of concentrations. Possibly the polysaccharides provide a concentrating surface, hence increasing the probability of reaction, and render adsorbed peroxidase more efficient as a catalyst. These suggestions receive support from the greater effect of starch on pyrogallol oxidation at lower peroxidase concentrations. Thus, with 0·5 μgm. of enzyme, an initial simulation (0·5 min.) of 100 per cent was observed, declining to 50 per cent after 3 min.

Starch–Agar-Gel Electrophoresis of Tuberculoproteins from Heated Culture Filtrates

IN order to improve the specificity of a bovine tuberculin purified protein derivative, precipitated with trichloracetic acid from heated culture filtrates[1], we decided to investigate its protein composition[2], and in this connexion we experimented with zone electrophoresis on paper-strips. Now this procedure has hitherto not been very successful[3-5], and in spite of our own numerous experiments with various procedures and methods we did not obtain anything other than unusable pictures of 'comets' or streaks. (This is in contrast with the more satisfying results obtained by others with non-heated tuberculins[4,5].) Smithies introduced starch gel electrophoresis which seems to be of great value in determining the ultrastructure of serum-protein patterns[6,7], the composition of toxins[8] and of cerebrospinal fluid[9]. Sorkin *et al.*[10] made preparative separations of some tuberculoprotein preparations from unheated culture filtrates by electrophoresis in starch gels, followed by transfer into glass. Our own investigations on this starch-gel electrophoresis led to the following method.

In order to prevent premature desiccating of the gels and to avoid the necessity of protecting them by placing covers and/or mineral oils on the surface and still to maintain a satisfactory consistency, we used 10 per cent w/v 'Merck Amylum Solubile' (*A.R.*) plus 0·27 per cent w/v 'Difco Bacto' agar. The agar was at first weakened for about 30 min. or longer in the buffer solution consisting of 15 gm./l. boric acid, 0·75 gm./l. bi-sodium salt of ethylenediamine tetraacetic acid and 2·5 mgm./l. 'Tween 80', brought up to *p*H 7·5 by adding about 6 gm./l. *tris* hydroxymethyl aminomethane. The mixture was then boiled until the agar was dissolved. After some time of cooling the solution, the starch was added, suspended, heated with continuous stirring and finally boiled for a few seconds. The liquid gel was poured out in plastic ('Perspex') trays to form layers of 240 mm. × 60 mm. × 3 mm., the trays having been placed in an electrophoresis apparatus with platinum electrodes. The electrode vessels and bridge vessels were filled with the above-mentioned buffer, only without 'Tween 80', and with sodium hydroxide instead of *tris* buffer. Thick filter-paper strips formed the connexion between bridge vessels and tray. After about 20 min. we made an incision, 8 cm. from the anodic side of the tray, with a thin blade and allowed 0·05–0·07 ml. of a protein solution of about 60 mgm./ml. to drip down slowly into the incision, even when it was scarcely visible on the surface. Immediately afterwards the gels were subjected to electrophoresis at room temperature for 17 hr. at 6 V./cm., then left to stain with Bayers 'Amidoschwarz 10 *B*' (2 gm./l. solution of methanol/water/acetic acid, 45 : 45 : 10) for 15 min., and washed with the same solution over a period of 1 hr., and repeated about 5 times with fresh solution. Fig. 1 shows the patterns of our bovine purified protein derivative tuberculin, solved from the lyophilized state by dialysing against a 0·25 per cent phenolic diluted buffer of *p*H 7 until the required protein concentration was reached; the '*C*'-like protein-fraction, prepared from the same purified protein derivative, fundamentally following Seibert's method[11] and the '*A* + *B*'-like proteins, prepared from the (purified protein derivative minus '*C*') remainder. Full details of these preparations will be described in a publication elsewhere.

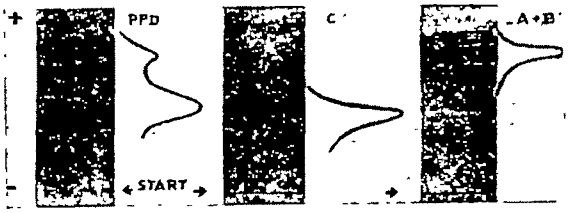

Fig. 1. The curves were obtained from colour diapositives of the patterns by photoelectric scanning

It appears from the purified protein derivative diagram that the proportion '*A* + *B*'/'*C*', calculated from planimetric measurement, is about a third, which is in accordance with the quantities of the chemically separated fractions. The '*C*'-like protein, its molecular weight probably being twice as great as that of the unheated '*C*' [11], is the slower one, in this respect quite the reverse of the unheated '*C*' in the Tiselius picture[2]. Furthermore, our '*C*'-like protein shows a greater tendency towards tailing than the '*A* + *B*'-like fraction.

These last two proteins appear to move closely together. *p*H's higher than 7·5 tend progressively to suppress separation while the lower ones tend to sharpen the zones but increase adsorption to the gel substance. Our results point to the combined effects of electric charge and particle size in starch-gel electrophoresis[13].

Effect of Pituitary Growth Hormone *In vivo* on the Phosphorus/Oxygen Ratios of Isolated Rat Liver Mitochondria

RECENT reports tending to localize the site of action of thyroxine in uncoupling oxidative phosphorylation at the level of the mitochondrial membrane[1,2] have served to emphasize the need for similar studies on possible sites of action of anterior pituitary growth hormone, a substance which produces generalized metabolic changes even more striking than those found with thyroxine. The present communication reports some results concerning the effect of the hormone on oxidative phosphorylation, using mitochondria isolated from the livers of normal rats or rats treated with growth hormone.

Rats were injected 4 hr. before killing either with 1 mgm. purified beef growth hormone or with 1–5

Table 1. PHOSPHORUS/OXYGEN RATIOS OF MITOCHONDRIA ISOLATED FROM THE LIVERS OF NORMAL AND GROWTH HORMONE-TREATED RATS

1 mgm. of growth hormone or 5 mgm. of bovine plasma albumin (Armour) injected 4 hr. before killing.

System. 0·3 ml. 0·3 *M* glucose; 0·1 ml. 0·04 *M* adenosine diphosphate; 0·1 ml. 3 × 10^{-4} *M* cytochrome *c*; 0·5 ml. 0·1 *M* phosphate buffer *p*H 7·4; 0·1 ml. 0·2 *M* magnesium sulphate; 0·05 ml. 1·5 *M* potassium chloride; 0·1 ml. 0·1 *M* versene *p*H 7·4; 0·3 ml. 0·1 *M* *dl*-β-hydroxybutyrate acid; 0·05 ml. hexokinase solution containing 50 units of enzyme activity; 0·2 ml. bovine plasma albumin (7·5 mgm./ml.); 0·2 ml. 0·02 *M* sodium fluoride and 1 ml. liver mitochondria (8 per cent suspension).

Temperature 27°. Time 5 min.

mgm. bovine plasma albumin. After killing, the livers were rapidly removed, the mitochondria isolated in 0·25 *M* sucrose and the phosphorus/oxygen ratios measured using a system adapted from that of Maley[3] with either *d*-, *l*-, or *dl*-β-hydroxybutyrate, *dl*-glutamate or reduced diphosphopyridine nucleotide as substrate.

Under the conditions employed here *d*-β-hydroxybutyrate was not oxidized at all, since *l*-β-hydroxybutyrate gave results exactly comparable with those obtained using the *dl*-salt. It will be seen that the mitochondria from growth hormone-treated rats have a lower phosphorus/oxygen ratio than those from normal rats, and that this difference can be largely ascribed to an increase in the rate of oxygen utilization rather than to any decrease in the rate of phosphorylation. The one-step oxidation of β-hydroxybutyrate involves the production of reduced diphosphopyridine nucleotide, and it is this latter compound which acts as substrate for the oxidative phosphorylation[4]. For this reason, the efficiency of the phosphorylation accompanying the oxidation of glutamate, an alternative source of reduced diphosphopyridine nucleotide, and diphosphopyridine nucleotide itself were studied. The phosphorus/oxygen values using these two substrates were lower than the values recorded for β-hydroxybutyrate (2·31 for glutamate and 1·77 for reduced diphosphopyridine nucleotide) and were entirely unaffected by prior treatment of the animal with growth hormone. Thus the ability of growth hormone to affect the efficiency of oxidative phosphorylation could only be demonstrated in one of the three enzyme systems tested, that is, β-hydroxybutyrate dehydrogenase and its associated electron transporting chain. It is interesting to notice that thyroxine also uncouples oxidative phosphorylation when β-hydroxybutyrate is used as substrate[1] although it should be observed that in this latter case the mechanism appears to be somewhat different from that shown by growth hormone (Table 1) in that thyroxine does not affect the oxygen uptake but causes a decrease in the associated phosphorylation.

In view of the widespread metabolic effects of growth hormone *in vivo* it would seem unlikely that the hormone has a specific effect on β-hydroxybutyrate dehydrogenase alone. Of the three substrates tested, only β-hydroxybutyrate seems to be oxidized exclusively by an 'internal pathway' (that is, one inside the mitochondrion) and since this enzyme is also the only one affected by prior treatment of the animal with growth hormone it would appear probable that the site of action of the growth hormone in lowering the efficiency of oxidative phosphorylation is at the level of the mitochondrial membrane, as has been suggested for thyroxine[1,2].

It is difficult to visualize a means by which a lowering of the efficiency of oxidative phosphorylation can be of advantage to an animal; but perhaps the lowered phosphorus/oxygen ratio is of secondary importance to the change in mitochondrial permeability. Ernster[5] has suggested that a reversible swelling of the mitochondria could provide a transfer system by which there could be an interchange of materials between the mitochondrial interior and cytoplasm. If the action of growth hormone is to alter the mitochondrial permeability then it is possible to consider that this effect of the hormone could, by permitting a transfer of metabolites or co-factors across the membrane, lead to increased metabolic activity which, even if there were some loss of efficiency in the coupling of some of the reactions, would be to the overall advantage of the animal. The increased rate of oxidation of β-hydroxybutyrate by the hormone-treated animal appears to point to such a possibility.

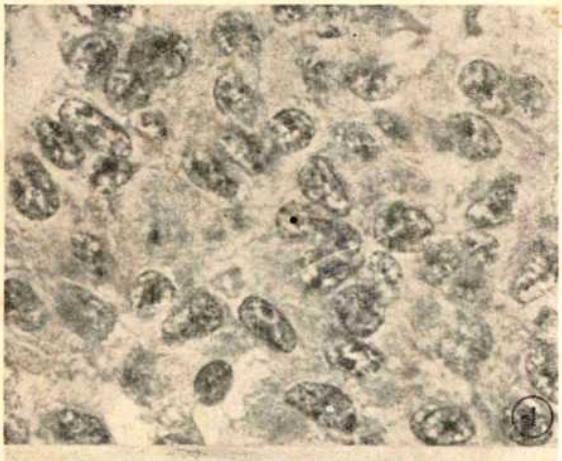
PHYSIOLOGY

Effects of Injection of Bovine Pineal Extract on the Nuclei of Rat Pineal Parenchymal Cells

THE pineal parenchymal cells are known to be rich in nucleoprotein[1,2]. Oksche[3] showed that pineal-cell nuclei contain a 'nucleolus apparatus' which extrudes some nuclear substance into the cellular cytoplasm. In general, the number of nucleoli and intranuclear granules in any cell is probably a useful index of the rate of protein synthesis[4]. This idea has led several authors to use pineal intranuclear changes as evidence of changed pineal functional status: both Oksche[3] and Quay[5] reported variations in pineal intranuclear activity owing to changes in illumination of their animals' cages. Quay[5] also correlated changes in pineal cell nuclei with periodic variations in pituitary gonadotropic activity.

The present communication describes changes in pineal nuclear status resulting from injections of a pineal extract. The occurrence of such changes suggests that exogenous pineal extract depresses pineal function in intact animals.

Studies were made on pineal glands from 15 Charles River rats which had been given intraperitoneal injections of a bovine pineal extract daily from the ages of 21–49 days; these were compared with the glands of control animals given saline injections.



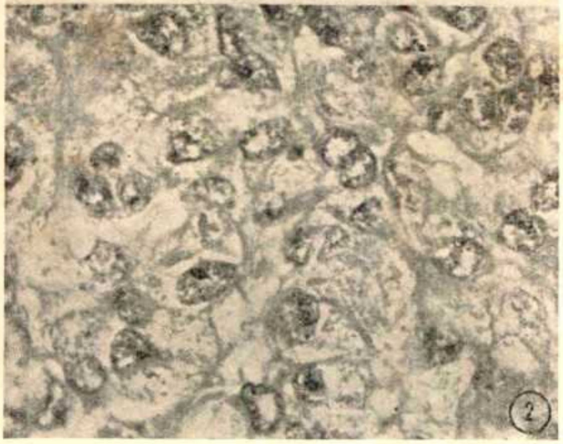


Fig. 1. The pineal parenchymal cells of the rat. Gomori's chrome hæmatoxylin–phloxin counter-stained in tartrazine (× *c.* 950). Fig. 2. The pineal parenchymal cells of a pineal-treated rat. Notice the decrease in number of nucleoli and in the amount of intranuclear material; the central portions of the nuclei are completely clear in many cases. The cytoplasm is also paler and less granular than in the control animals. Gomori's chrome hæmatoxylin–phloxin counter-stained in tartrazine (× *c.* 950)

The bovine pineal extract was prepared essentially according to the method described elsewhere[6].

The pineal glands were fixed in Bouin's solution to which 1 per cent calcium chloride had been added; they were stained with Gomori's chrome hæmatoxylin–phloxin and in phloxin and then counterstained with tartrazine according to Lendrum[7]. (The treatment with hæmalum was omitted.) The sections were cut at 3–4μ. The number of phloxinophilic nucleoli above approximately $0 \cdot 5\mu$ in diameter were counted.

The pineal parenchymal cells of the rats which had been given pineal extract showed a marked decrease in the number and size of the nucleoli and the amount of granular material in the nuclei (Figs. 1 and 2). The decrease in number of nucleoli in the pineal-treated animals was statistically significant ($P < 0 \cdot 001$). A slight decrease in the size of the pineal cells themselves was noted in the glands of the treated animals; the cytoplasm appeared less dense than in the control animals.

Caspersson[4] showed that a decrease in the number of nucleoli and intranuclear granules in cells indicated a reduced rate of nuclear synthesis. The decrease in the intranuclear granular and nucleolar material observed here in rats given a bovine pineal extract must therefore indicate that such extracts depress nuclear activity in the pineal cells of injected animals. Secretory activity in the pineal cell is known to be correlated with nuclear activity[3]. The reduced pineal nuclear activity found here therefore suggests that pineal cellular secretory activity might also be reduced. If the latter phenomenon does occur in these circumstances, it might be taken as an indication of suppression of endogenous pineal secretion caused by increased circulating pineal hormone owing to the injection of bovine pineal extract.

The pineal glands of rats given daily intraperitoneal injections of a bovine pineal extract for 28 days starting at the age of 21 days showed decreased numbers of nucleoli and intranuclear phloxinophilic granules. This finding was taken to indicate depression of pineal cellular secretory activity owing to the increase in circulating pineal hormone caused by the injection.

Seromucoid Contents of Human Bile

VARIATIONS of seromucoid in pathological conditions and its clinical significance have been extensively investigated during the past few years. Greenspan[1], Winzler[2] and others have shown the seromucoid contents in the blood of normal human subjects to be $12 \cdot 4 \pm 0 \cdot 5$ mgm. per cent as expressed in hexose, and $3 \cdot 38 \pm 0 \cdot 27$ mgm. per cent as expressed in tyrosine. Seromucoid contents in the blood are significantly increased in obstructive jaundice and are decreased to very low figures in jaundice due to hepatitis. These pathological variations suggest the possibility of the liver playing an important part in seromucoid metabolism. Since for the time being the site of formation and metabolic fate of seromucoid are unknown, it has occurred to us that it might be synthesized by the liver or at least partly eliminated in the bile. We have therefore investigated the presence and contents of seromucoid in human hepatic bile.

Samples of hepatic bile draining through a Kerr tube were collected from patients who had undergone cholecystectomy. The bile was collected in the morning in post-absorptive conditions, during the last days preceding the removal of the Kerr drain, when the bile contained but a few cells and flakes of mucus were no longer present. Hepatic bile was also collected by duodenal catheterization in three patients who had undergone cholecystectomy 2, 3 and 5 years previously. The bile was immediately centrifuged at 12,000 r.p.m. for 15 min. and then filtered through Schleicher Schüll filter paper No. 589 (blue band).

Table 1. SEROMUCOID CONTENTS OF HUMAN HEPATIC BILE

Hepatic bile case	Hexoses (mgm. per cent)	Tyrosine (mgm. per cent)	Total solids (gm. per cent)	Hexoses in mgm. per 100 gm. of total solids	Tyrosine in mgm. per 100 gm. of total solids
P. E.	8·0	1·27	2·84	281	52·0
T. A.	6·0	0·95	2·50	240	37·8
G. O.	13·5	1·81	2·35	574	77·0
A. B.	9·2	0·38	3·08	298	12·0
T. P.	8·6	0·29	3·84	224	8·0
T. M.	2·4	1·14	4·12	58	27·0
C. V.	9·0	4·00	4·70	191	85·1
M. G.	12·0	6·80	3·37	356	101·0
Z. I.	7·0	2·64	5·56	126	47·0
W. K.	8·5	1·10	3·02	281	36·4
S. A.	6·7	0·90	2·75	244	32·6
V. H.	5·8	2·50	2·85	203	87·7
C. B.	6·5	0·85	3·20	203	27·7
±*S.E.*	7·93 ± 0·89	1·89 ± 0·49	3·39 ± 0·25	252·23 ± 18·52	48·5 ± 16·31

The clear bile obtained by these means was tested for the presence of seromucoid according to Winzler's method as modified by Weiner and Moshin[3]. Tyrosine as well as hexose contents were determined.

The total solid contents were determined in the same samples.

Seromucoid was present in all the samples of hepatic bile investigated. The seromucoid concentration in hepatic bile, as expressed in mgm. hexose and mgm. tyrosine per 100 gm. of total solids, the averages of these figures and the standard errors of the averages are listed in Table 1.

It can be seen that:

(1) The total solid contents of hepatic bile display a considerable degree of variation (3·39 ± 0·25 gm. per 100 ml.).

(2) There are great variations of seromucoid concentrations in fresh hepatic bile, both as expressed in terms of hexoses (7·93 ± 0·89 per 100 ml.) and in terms of tyrosine (1·89 ± 0·49 mgm. per 100 ml.).

(3) These fluctuations are not reduced by referring seromucoid concentrations to the total solid contents of the bile; it follows that variations of the latter cannot wholly account for these fluctuations.

No investigations were made on hepatic bile obtained by duodenal catheterization from normal subjects in order to avoid so far as possible the contamination of hepatic bile samples by mucus secreted by the extrahepatic bile ducts and by the duodenal wall. By collecting the bile draining through a Kerr tube, this bias is minimized. We consider the presence of seromucoid in hepatic bile to be unquestionable evidence of the elimination of this glycoprotein by the liver. This might be due either to excretion through the liver of the seromucoid present in the blood, or to synthesis in the liver of the seromucoid which is afterwards eliminated via the bile and possibly the blood. Further investigations are required in order to show seromucoid synthesis in the liver. However, the presence of seromucoid in hepatic bile is clear evidence of the part played by the liver in the elimination of this substance.

Distribution of Chromactivating Hormones in the Pituitary of the Minnow

IN a previous communication[1], I have described the distribution of melanophore-aggregating hormone in the pituitary of the minnow (*Phoxinus phoxinus*). By use of the method described there the distribution of minnow erythrophore-dispersing and frog melanophore-dispersing factors in the minnow pituitary has been investigated.

Erythrophore-dispersing activity was determined by scoring the degree of reddening around the pectoral and pelvic fins of black-adapted minnows (60–65 mm. long) from 0 (no reddening) to 6 (maximum reddening) 1 hr. after intraperitoneal injection of the aqueous gland extract; the minnows used were selected for uniformity of response to a standard dose of an extract of whole minnow pituitaries. Frog melanophore-dispersing activity was determined by measuring the melanophore-index of the web melanophores of the hind foot of white-adapted frogs (*Rana temporaria*) (20–25 gm. in weight) immediately prior to injection of the aqueous gland extract into the dorsal lymph sac and again 1 hr. after the injection. The results are summarized in Table 1.

Table 1

		Pituitary region	
		Anterior	Posterior
Response of erythrophores of black-adapted minnows. Change in erythrophore score 1 hr. after injection	No. of animals	15	15
	Mean response	1·33	4·93
	S.D.	2·225	1·982
		$P < 0{\cdot}01$	
Response of melanophores of white-adapted frogs. Change in melanophore-index 1 hr. after injection	No. of animals	6	6
	Mean response	1·27	3·47
	S.D.	1·212	0·392
		$P < 0{\cdot}01$	

The experiments reveal that the erythrophore-dispersing and melanophore-dispersing factors in the minnow pituitary are distributed in the same way as the melanophore-aggregating factor; that is, they are present in both the anterior and posterior portions but in significantly higher concentration in the posterior portion. Stahl[2] has described two distinct cell types in the meta-adenohypophysis of *Mugil* and suggests that they represent the source of the melanophore-aggregating and melanophore-dispersing hormones. If this is true it is necessary to explain the presence of substantial amounts of these hormones in the anterior part of the gland. Comparison of the values determined for hormone activity in the two regions of the gland with dose-response curves (unpublished work) suggests that the level of both melanophore-aggregating and melanophore-dispersing hormone in the posterior part is about five times greater than that in the anterior part. In view of the crude technique adopted in separating the two portions of the gland it would be reasonable to suppose that some 20 per cent of the meta-adenohypophysis was in fact included in the anterior portion in these experiments. The results described here and in the previous communication thus lend support to Stahl's suggestion. It must be admitted, however, that such an interpretation cannot easily be reconciled with the observations of Healey[3] on the minnow or Enami[4] on *Parasilurus asotus*.

The similarity in distribution of the melanophore-dispersing and erythrophore-dispersing factors adds support to the generally accepted view[5] that both effects are brought about by a single hormone. However, the results of these experiments do not preclude the possibility that either three distinct hormones, or a single hormone causing melanophore-aggregation and erythrophore-dispersion in the minnow, and melanophore-dispersion in the frog, are involved.

Thanks are due to the Department of Scientific and Industrial Research for a Research Fellowship and to Prof. N. Millott for the provision of facilities.

Effect of Denervation on Potassium-42 Uptake by the Rat Muscle *in vitro*

WIDELY different reports exist concerning the changes in potassium-42 uptake by denervated muscle. Lyman[1] found an increased uptake after denervation. Fischer *et al.*[2] could show no differences in uptake between normal and denervated muscles in the rabbit. Finally, Harris and Nichols[3], who measured the uptake of potassium-42 into denervated frog muscle *in vitro*, reported, in agreement with their previous results[4], that the uptake is decreased.

Difference between the findings of Lyman[1] and Harris and Nichols[3] may be due to: (*a*) different uptake of potassium into frog and rat muscles; (*b*) different equilibration time of the isotope; or (*c*) different degrees of atrophy in the frog and rat muscles. Muscle atrophy in the frog, which was studied by Harris and Nichols[3], progresses very slowly, whereas muscles in the rat studied by Lyman[1] atrophy considerably more during the same period.

For this reason we investigated the question whether uptake of potassium-42 into frog and rat muscles is different when the equilibration time of the isotope and the degree of muscle atrophy are the same. The uptake of potassium-42 into normal and denervated diaphragm of the rat was therefore measured five days after denervation, that is, in a mammalian muscle, in which atrophy begins 20–40 days after denervation[5].

Experiments were performed on male rats of 90–100 gm. body-weight. The diaphragm was denervated by unilateral ligature of the phrenic nerve by the abdominal route. Five days after denervation, rats were killed and completeness of denervation was controlled by faradic stimulation of the phrenic nerve. The diaphragm was excised together with the rib, and after dividing it into halves the centrum tendineum was removed and the hemidiaphragms were incubated in 5 ml. of saline containing chloride labelled with potassium-42. Following incubation, the hemidiaphragms were carefully washed, isolated from the rib, and gamma-activity of the tissue was measured. The total content of potassium was determined by the flame photometer in the same way as previously described[6].

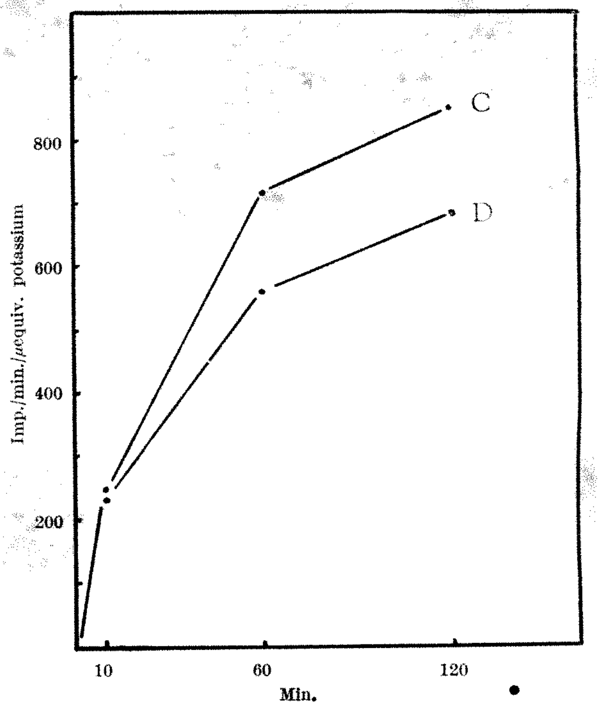

Fig. 1. Uptake of potassium-42 by normal and denervated hemidiaphragm. *D*, Denervated; *C*, control muscle

It was found that the uptake of potassium-42 by denervated hemidiaphragm is lower than in the control half (Table 1). The decrease in uptake becomes evident only after a longer period of incubation. After 10 min. incubation the uptake was the same on both the normal and denervated halves. Following 60 min. equilibration, the uptake was decreased by 118 ± 14·6 imp./min./μequiv. potassium, that is, by 16·6 per cent, while after 120 min. the uptake was decreased by 169 ± 41·5 imp./min./μequiv. potassium, that is, by 19·9 per cent (Fig. 1).

It was concluded from these results that under the same experimental conditions the uptake of potassium-42 by denervated muscle of the rat is decreased similarly to that of frog muscle[3]. Differences of uptake by denervated muscles are not caused by tissue specificity. The equilibration time of the isotope is an especially important factor when studying this uptake. The lower potassium-42 uptake

Table 1. UPTAKE OF POTASSIUM-42 BY NORMAL AND DENERVATED HALVES OF THE DIAPHRAGM

Time of incubation (min.)	Imp./min./μequiv. potassium		
	Denervated (*D*)	Control (*C*)	*D*—*C*
10	230	244	− 14 ± 23·8
60	596	714	− 118 ± 14·6
120	681	850	− 169 ± 41·5

Hemidiaphragms were incubated in 5 ml. Krebs–Ringer–bicarbonate saline with chloride labelled with potassium-42 (0·25 μc./ml.) in Erlenmeyer flasks at 37° C. The gaseous phase in the flask was 95 per cent oxygen + 5 per cent carbon dioxide. Each value is the average of five determinations.

occurred neither in our experiments nor in those of Harris and Nichols[3] until after a long period of equilibration. Lyman[1] showed an increased uptake after 2–9 min. of equilibration. However, in two experiments in which equilibration time lasted for 4 hr., he also found less potassium-42 in the denervated muscle (75 and 89 per cent). As has been shown in the literature as well as in the present report, the uptake of potassium-42 by denervated muscle following a longer period of equilibration is decreased. This conclusion further corroborates our previous findings concerning the restitution of potassium following various experimental conditions which were found to be retarded[7,8].

Histochemical and Biochemical Studies of Rat Liver in Experimental Cirrhosis after Partial Hepatectomy

As an outcome of our earlier work on experimental cirrhosis[1,2] and regeneration of the liver[3] it seemed of interest to study the dynamics of the regenerative process in the normal and cirrhotic liver after partial hepatectomy.

The experiments were made on 90 male Wistar rats of 170 gm. average body-weight divided into two groups and kept on a standard diet. In the animals of group 1 cirrhosis was produced with carbon tetrachloride (0·1 ml. subcutaneously every fourth day, a total of 29 doses over a 120-day period), while group 2 was untreated. Partial hepatectomy (65–70 per cent) was made on both groups and rats were killed 24, 48, 72 and 96 hr. after surgery. The removed lobes and postsurgical remnants were examined by histomorphological, histochemical and biochemical methods.

Succinic dehydrogenase activity (neotetrazolium method) in the cirrhotic liver proved to be somewhat less than in the normal one. The activity of this enzyme decreased very much in both groups 24 hr. after partial hepatectomy. This decrease in normal livers persisted unaltered for 3 days and a partial return of the activity was seen only on the fourth day. In contrast to this, the activity of succinic dehydrogenase of the regenerating cirrhotic liver reached that of the intact (unoperated) cirrhotic liver within 48 hr., and after 96 hr. closely approached that of the normal controls. The succinic dehydrogenase activity was also measured by a quantitative biochemical procedure[4]; the results of these determinations confirmed entirely those obtained by the histochemical technique.

Acid and alkaline phosphatase activities were studied both by histochemical procedures (Gomori–Moffat) and by quantitative methods using liver suspensions[5,6]. The results of both types of analysis were in agreement; the quantitative results are shown in Table 1. There was a substantial increase in the alkaline phosphatase activity both in the cirrhotic and normal livers 24 and 48 hr. after partial hepatectomy, the activities returning to the pre-operative levels by 96 hr.; the alkaline phosphatase activities in cirrhotic livers were generally much higher than in the normal organ. The acid phosphatase-levels were somewhat variable in normal livers after hepatectomy, but showed substantial increases in the regenerating cirrhotic livers.

Table 1. ACID AND ALKALINE PHOSPHATASE ACTIVITIES IN NORMAL AND CIRRHOTIC LIVER AFTER PARTIAL HEPATECTOMY

Hours after hepatectomy	Normal liver			
	Acid phosphatase		Alkaline phosphatase	
	Per wet weight	Per dry weight	Per wet weight	Per dry weight
0	500	1,530	43	130
24	323	1,075	106	351
48	412	1,425	187	646
72	614	2,106	122	418
96	497	1,651	38	124
	Cirrhotic liver			
0	295	1,143	84	324
24	416	1,445	206	717
48	577	2,042	360	1,274
72	426	1,508	100	354
96	515	1,840	116	378

The activities are given as μgm. inorganic phosphorus liberated per hr. from β-glycerophosphate by 100 mgm. of wet or dry liver tissue. The inorganic phosphorus was determined by the method of Fiske and Subbarow (ref. 5).

In histochemical preparations the activity of lipase (Gomori's method) was seen to decrease early after partial hepatectomy in both groups of animals, but a return to normal followed quickly.

Cytochrome oxidase was also measured according to the method of Mitolo and Ruccia[7]. The activity of this enzyme showed a periodic change (decrease→return to normal→decrease) in the regenerating normal liver, whereas in the regenerating cirrhotic liver there was more than a threefold increase even on the fourth day after hepatectomy.

We could not observe any change in the architecture of the cirrhotic livers after partial hepatectomy. The mitotic activity seemed, however, greater in the cirrhotic post-operative remnants than in the non-cirrhotic ones during the early days of regeneration.

The results indicate that the enzymic responses of the cirrhotic liver after partial hepatectomy are more intense than those of the normal regenerating one. A more detailed study of this phenomenon and the evaluation of its significance in the regenerative process is in progress.

RADIOBIOLOGY

Whole-Body Turnover of Selenium in the Rat

Selenium has recently been shown to be an essential micronutrient for rats[1] and ruminants[2]. These discoveries have directed attention to the lack of information concerning the metabolism of selenium in subtoxic amounts. The present communication gives results for whole-body turnover, or total excretion, of selenium by the rat over a prolonged period of time.

Hooded rats of the Long–Evans strain were used. They were maintained on a complete stock colony ration (*ad libitum*) and weighed approximately 150 gm. at the time of administration of radioactive selenium; 0·0011 mc. of selenium-75 in physiological saline was administered interperitoneally. The total selenium content of the dose was 0·14 mgm. and the selenium was present as sodium selenite. The total selenium-75 content of the rats was determined three times daily for the first two days, twice daily for one week and daily for a second week. For measurement, individual rats were placed in a ventilated stainless steel tube and confined to a length approximately equal to that of the rat's body. The rat was then suspended approximately 20 cm. above a scintillation counter for measurement of radiation. The counter used was a standard well-counter operated without the top lead shield. The entire top surface of the crystal was unshielded. The 0·269-MeV. gamma-ray of selenium-75 was counted, using a single-channel pulse-height analyser and scaler. For calibration, a vial containing an aliquot of the dose was substituted for the rat. The standard error of measurement was 2·3 per cent as determined from duplicate counts[3]. There was no difference in the error of measurement between two operators.

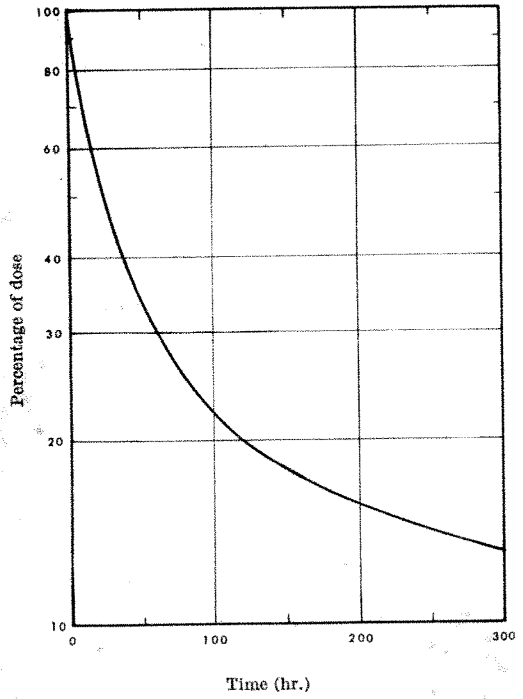

Fig. 1. Radioselenium turnover in the rat

Table 1. Whole-body Turnover of Selenium in the Rat

Rat No.	Rate constants (hr.$^{-1}$): K_1	K_2
0	0·037	0·0025
1	0·037	0·0018
2	0·036	0·0021
3	0·037	0·0025
6	0·040	0·0023
7	0·036	0·0021
9	0·038	0·0021
Mean	0·037	0·0022
Standard deviation	0·001	0·0002
$t_{1/2}$ (hr.)	19	318

The results were analysed by considering the whole-body turnover to be describable by a set of consecutive first-order chemical reactions. The rate constants for the various segments of the turnover curve were computed, fitting the data by the method of least squares.

For the first 300 hr. after injection of selenium-75, the whole-body turnover may be described by two first-order processes of widely differing rate constants (K_1 and K_2). A graph presenting the average results is shown in Fig. 1. The initial slope of the curve is determined by K_1 and the final slope by K_2. The individual rate constants are presented in Table 1.

Previously published work of selenium metabolism was for periods of less than 50 hr. and hence comparison is difficult. Also, other studies measured excretion, rather than retention, and often ignore one of the three routes of selenium excretion—urine, fæces and expired air. Harshfield[4] found the 'total recoverable selenium' in the rat to be about 75 per cent of dose at 6 hr. after injection and about 65 per cent of dose at 12 hr. These results agree with the present work. Harshfield found, however, no decrease in 'total recoverable selenium' between 12 and 48 hr. post-injection as was found here (see Fig. 1). McConnell[5] found the urine and fæcal excretion of selenium-75 from the mouse to be about 45 per cent of dose in the first 24 hr. The present work indicates a total excretion of about 48 per cent of dose in an equivalent time. Heinrich and Kelsey[6] reported the 'total recoverable selenium' in the mouse to be only 16·5 per cent of dose at 48 hr. after injection—considerably less than that found here for the rat.

The presence of two rate constants governing selenium turnover indicates that selenium is involved in the metabolism of the animal. Selenium is transferred from one (rapidly excreted) form to another (slowly excreted) form. Two choices are available: (1) the rate-limiting processes are the renal clearance of two chemically different forms of selenium; and (2) the rate-limiting process for the smaller rate constant is the rate of release of selenium from tissues in which it is fixed.

I acknowledge the assistance of Miss July Grafton with the laboratory procedures and Dr. W. B. Dye for his encouragement and counsel.

Selection of Iodinated Protein in the Young Mouse

The suckling mouse absorbs antibody readily when whole immune serum is administered by mouth[1] and transmission to the circulation is selective in the sense that antibodies prepared in a variety of species are characterized by different concentration quotients in the recipient plasma[2]. During the course of the work with serum protein preparations labelled with iodine-131 in other species a criterion of the physiological integrity of the labelled material was sought which would be sensitive and readily determined. Recourse was therefore made to gut transmission in the young mouse.

The mice employed throughout the work were L.A.B. Greys, obtained by courtesy of Dr. Lane-Petter in 1955 and bred randomly since then. Preliminary experiments suggested the standard conditions of testing. Protein, labelled by the jet-burette method[3], was made up finally in 1 per cent solution. This was fed to 8-day old mice which were killed 3 hr. later, the blood collected, and the activity of the serum protein determined after tungstic acid precipitation.

Values are expressed as the ratio:

$$\text{concentration quotient} = \frac{\text{c.min.}^{-1}\ \text{ml.}^{-1}\ \text{serum protein}}{\text{c.min.}^{-1}\ \text{ml.}^{-1}\ \text{preparation fed}}$$

Fig. 1*A* presents the regressions of the concentration-quotient with dosage for two levels of iodination of aliquots of a frozen-dried stock preparation of rabbit globulin which was prepared by final precipitation from 12 per cent sodium sulphate[4]. It is apparent that a very sharp selection occurs between these two preparations, although they differ only in the level of iodine-127 per molecule of globulin.

Fig. 1*B* illustrates the relation of concentration quotient to iodination-level at a chosen dose of 0·03 ml. fed, and is thus in effect a calibration curve for the testing of subsequent preparations of this protein at any future date. It is clear that there is no significant difference between the concentration quotient at the mean iodination-level of 0·5 atom per molecule and that for antibody from whole rabbit serum at the same dosage (Fig. 1*A*), so that it is possible to take the concentration quotient of isotope at this level as being maximal for the stock preparation of globulin in these experimental conditions. Since the reduction of concentration quotient at the mean level of 3 atoms per molecule is already highly significant, the proposed test is clearly a sensitive one. It is thus possible, by feeding small groups of mice, to check the integrity of labile preparations in the course of a few hours.

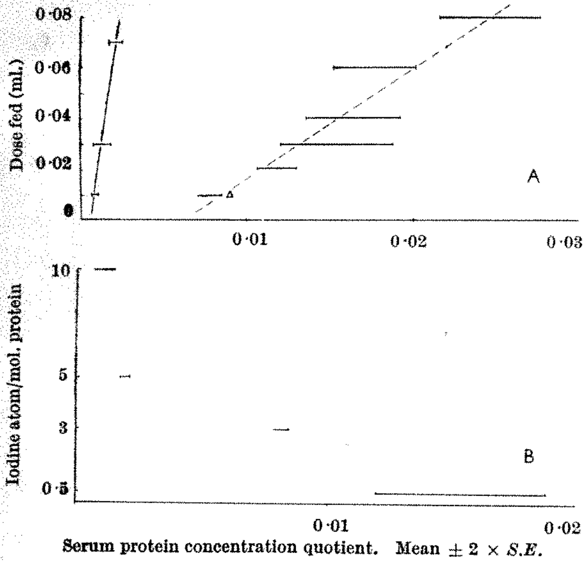

Fig. 1. Absorption of 1 per cent solutions of rabbit globulin from the gut of the 8-day old mouse. The means ± 2 standard error of groups of six mice are plotted; within each relationship each group was composed of one sibling of each of six litters. (*A*) Dosage relation: – – – –, regression where the mean iodination-level is 0·5 atom/mol. *b* = 4·4; ———, regression where the level is 10 atom/mol. *b* = 49·4; △ = mean concentration quotient of rabbit anti-sheep red cell serum from ref. 2. (*B*) The test calibration curve: dose fed 0·03 ml.

Selection between molecules differing only in the number, and presumably the distribution, of labelled tyrosine residues, since it is so sharp, may suggest that some at least of the tyrosine residues of the molecular surface normally play a part in selection of the protein by the entoderm cell.

Cæsium-137 in Toronto Milk during 1959

MEASUREMENTS of the changing cæsium-137 content of milk have been carried out in many parts of the world, particularly in the United States[1] and the United Kingdom[2]. The Los Alamos group measured the activity of Ontario milk during 1958[3]. Here we present results of measurements on milk taken from the Toronto milk-shed during the period April 1959–February 1960.

The measurements were carried out using as gamma-ray detector a 5-in. sodium iodide crystal placed in the University of Toronto 'steel room'[4]. 670 gm. of dried skimmed milk, received within a few days of production, were placed in a thin copper vessel immediately below the crystal. Counting was normally for 75 min.

The only photo-peaks observed were at energies of 0·66 MeV. and 1·46 MeV., corresponding to cæsium-137 and potassium-40 activities. By comparison of the areas of these photo-peaks, and making suitable corrections[4], the ratio cæsium-137/potassium of a sample is obtained. Calibration of the apparatus was carried out regularly using a weighed amount of potassium chloride in a standard copper vessel, and thus the potassium content of the milk could be determined, corrections once again being necessary for the differential absorption of the potassium gamma-rays in the potassium chloride and in the dried milk. It was in fact found that the potassium content of each sample of dried milk was approximately the same, the average value being 3·7 mgm. of potassium per gm. of dried milk.

The statistical error associated with the measurement of the potassium content of any one particular milk sample did not exceed 2 per cent.

The results for cæsium content during the period of observation, expressed in cæsium units (C.U.), that is, μμc. cæsium-137 per gm. of natural potassium, are given in the lower part of Fig. 1. For comparison,

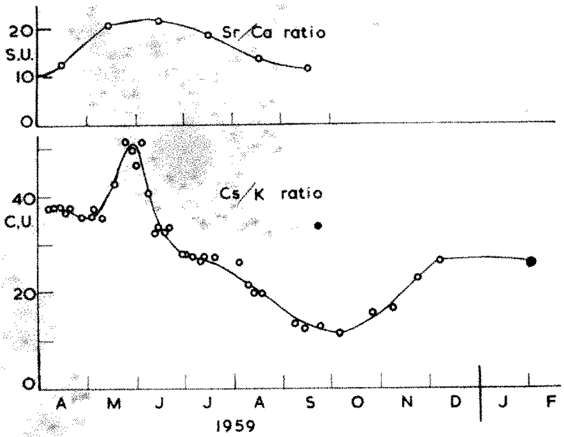

Fig. 1. Lower graph: change with time of the cæsium content of Toronto milk during April 1959–February 1960. (C.U. = μμc. cæsium-137 per gm. potassium.) Upper graph: Canadian average strontium-90/calcium ratio in milk (ref. 5). S.U. = μμc. strontium-90 per gm. calcium

the averaged ratio strontium-90/calcium for milk in Canada for the corresponding period[5] is given in the upper part of Fig. 1.

We interpret the cæsium curve in the following way:

(1) During April, cows are in barns, on winter feed, the cæsium-137 content of which will reflect the mean rate of fallout of the previous summer. Thus little change in the ratio cæsium/potassium in milk from these cows is expected in this period.

(2) The cows from which our milk came went out to pasture during the second week of May. This pasture would be contaminated with the fallout from the low-altitude Russian bomb tests of late 1958. As a result, the cæsium content of the milk rose rapidly after the change over to summer-feed. It will be noted that the time for the cæsium content to change by half the difference between the winter-level and the peak is approximately 12 days. The biological half-life of cæsium in the cow is stated to be about 20 days[6].

(3) The Russian fallout was apparently retained only a short time in the atmosphere, and after the rapid rise to the peak of 51 C.U. at the end of May, the cæsium activity in milk fell to the low value of 11·6 C.U. in October. This decrease seems to have two components, one rapid and one relatively slow. We attribute the former to the fact that cows grazing on new grass would pick up activity collected on the grass over about one month, while the second-growth grass would only have on it fallout collected over perhaps one or two weeks.

(4) In early November or late October the cows returned to the barns, to feed on hay, etc., cut during the early summer of 1959. As a result, the ratio cæsium/potassium rose, this time to a level equal to that of July 1959. Unfortunately, supplies of dried milk have been poor during the winter, and the presence of a plateau is only shown by the approximate equality of runs in late November and early December using dried milk, and one run in February 1960 using liquid milk.

It may be noted that during the summer decrease, during July 1–September 30, the cæsium content of milk fell by a factor of 2. On the assumption that cæsium-137 intake by cows is via direct fallout on foliage and not via the roots of plants, this suggests a half-life in the troposphere of the fallout of the order of 2 months.

The fact that there are two distinct rates of decrease of the cæsium/potassium ratio supports the assumption that most of the cæsium entering cattle comes directly from the foliage rather than via the grass root-system.

Comparison with the strontium-90 results show that the rise occurs in strontium content at the same time as the rise in cæsium content, and that correspondingly there is a fall throughout the summer in the strontium activity. However, the ratios of the spring peak values to the winter 1958–59 plateau values for cæsium-137 and strontium-90 are different (10 : 7 and 2 : 1 respectively) and the rate of decrease of the cæsium-137 content of milk was greater than that for strontium-90.

The October 1959 low value of 11·6 C.U. corresponds to an activity of approximately 19 μμc. of cæsium-137 per (Imperial) quart of milk. Assuming a 115-day biological half-life for cæsium in the body[7], and an intake of one quart of milk a day, this activity leads to a total maximum body burden due to this source of cæsium of $3\cdot1 \times 10^3$ μμc., which is 10,000 times less than the maximum permitted amount in the body[8].

HISTOLOGY

A Specific Stain for Mast Cell Granules

Examination of tissues stained for mast cells with a variety of accepted techniques has shown a need for a more specific staining method. The use of the conventional metachromatic dyes, though resulting in satisfactory preparations in many cases, presented problems of identification of mast cell granules in some tissues, for example, in lymph nodes where the intense nuclear orthochromatic staining of surrounding cells obscures metachromatic granules.

As recently as 1957, Barlow[1] was prompted by "a lack of a sufficiently reliable and selective method of identification" for mast cells to formulate a tribasic stain for their differential staining. The constituents for this tribasic stain were acridine red, neutral red, and basic fuchsin, but unfortunately the staining technique was lengthy and complicated.

When using metachromatic dyes, background or orthochromatic staining of tissue elements can be completely suppressed by acidifying the dye solution and adding metallic cations in suitable concentrations[2]. In dilute solutions, however, lengthy periods of immersion in the dye were necessary to produce even faint metachromatic staining of the mast cell granules. In order to increase the speed and intensity of the granule staining, dye concentrations were increased, and background staining was avoided by increasing the metallic cation concentrations.

The tissues employed were obtained from the lip and tongue of young adult Chester Beatty albino rats. These tissues were fixed in 10 per cent neutral formol saline, embedded in paraffin wax–'Celloidin' by Peterfi's method, and cut in serial section at 7μ thickness. These techniques have been shown to be satisfactory for the demonstration of mast cells in tissues obtained from the albino rat[3].

A 0·01 per cent toluidine blue solution buffered at *p*H 3·0 with a 1 in 10 dilution of McIlvaine's sodium hydrogen phosphate citric acid buffer was found to stain satisfactorily mast cell granules in 10 min. A concentration of 2 gm. per cent crystalline magnesium chloride, that is, 0·2 *N* concentration, was required to prevent background or orthochromatic staining. Except for faint staining of cartilage matrix, this solution was specific for the granules of mast cells (Fig. 1).

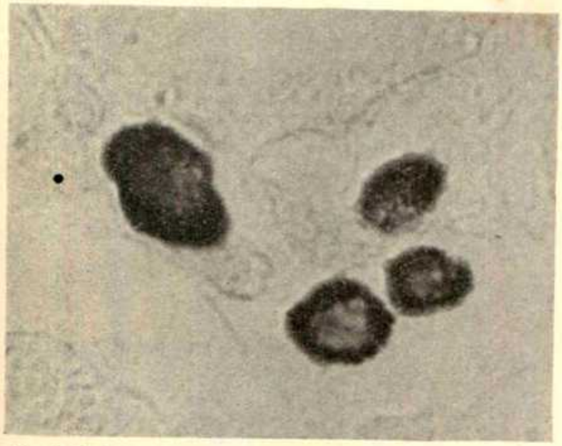

Fig. 1. Staining of mast cell granules with complete suppression of background staining. (× 1,000)

Nuclear fast red stained the nuclear material without interfering with the granule staining.

W. Montagna (personal communication, 1956) suggested that much 'washing out' of a metachromatic dye by the low-grade alcohols during dehydration procedures could be avoided by using tertiary butyl alcohol instead of the various grades of ethyl alcohol. As tertiary butyl alcohol was unobtainable, the closely related *iso*-propyl alcohol was used as a substitute and found to have no apparent deleterious effect on the toluidine blue staining.

Montagna's recommendation to employ toluene as a clearing agent has also given satisfactory results. In later work terpineol has been substituted for toluene, as it is less volatile and, therefore, easier to use. The results were similar to those obtained with toluene.

Diffusion of the dye into the mounting medium has been prevented by employing toluene-balsam, and avoiding heat in drying the mountant. Sections prepared in this manner have remained unchanged over a period of three years.

The technique for the 'specific' stain is as follows: (1) remove paraffin wax with xylene, and hydrate in descending grades of ethyl alcohol; (2) wash in distilled water; (3) immerse in a 'pretreatment' solution of a 1 in 10 dilution of McIlvaine's sodium hydrogen phosphate citric acid buffer at *p*H 3·0 for 1 hr.; (4) stain for 10 min. in a 0·01 per cent toluidine blue (Gurr 2706) solution in a 1 in 10 dilution of buffer at *p*H 3·0 to which 2 gm. per cent crystalline magnesium chloride have been added; (5) counterstain with 0·1 per cent nuclear fast red (Gurr 3569) for 5 min.; (6) rinse in distilled water; (7) dehydrate with three changes of *iso*propyl alcohol for 2 min. each; (8) clear in toluene or terpineol; (9) mount in toluene-balsam, and dry away from heat.

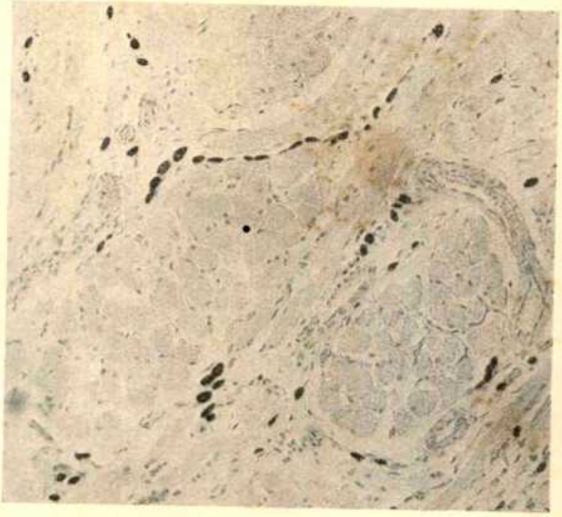

Fig. 2. 'Specific' stain preparation with mast cells clearly visible. (× 120)

With this technique the granules of mast cells are stained heavily with the toluidine blue, and the cartilage matrix faintly blue. Nuclei are stained red (Fig. 2).

In order to establish the precise relationship of the nuclei to the granules of the mast cells stained by the 'specific' stain, a composite Feulgen reaction 'specific' stain was carried out on sections of lip and tongue.

The Feulgen reaction (after Pearse[4]) was carried out first, without counterstain. The sections were then immersed in the 'pretreatment' buffer solution for 1 hr., and then stained with the 'specific' stain. Nuclear fast red counterstain was omitted from the 'specific' stain procedure.

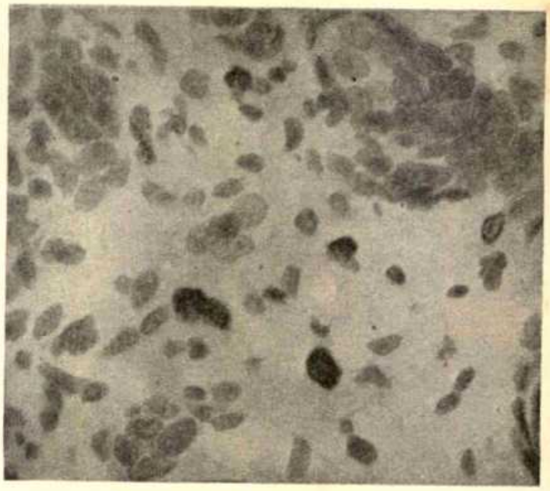

Fig. 3. Composite Feulgen reaction–'specific' stain. (× 540)

It was found that the subsequent staining of the mast cell granules by the toluidine blue was not affected by the preceding treatment of the Feulgen reaction. The granules remained metachromatic, and the nuclear chromatin was stained red from the Feulgen reaction.

The relationship of the granules to the nuclei was clearly apparent in those cells which contained only moderate numbers of granules (Fig. 3). In some cases, however, the granules were so numerous that the nuclear staining was obliterated. The distribution of the Feulgen-positive material corresponded to the nuclei demonstrated by the nuclear fast red in the 'specific' stain.

The 'specific' stain applied to frozen sections has given similar results to those of paraffin wax–'Celloidin' sections.

Ultrastructure of the Clear Cells in Renal Carcinomas and its Importance for the Demonstration of their Renal Origin

MOST pathologists will agree that the histogenesis of the so-called Grawitz tumours of the kidney was settled by the classical paper of Stoerk published in 1908 [1]; but the arguments of this author, convincing as they were in disproving the suprarenal nature of the 'hypernephroma', were much less so in demonstrating their renal origin. That is the reason why this latter opinion has been challenged time and again. New theories have been put forward, among which those of Apitz[2] and of Feyrter[3] have attracted some attention lately.

It seemed interesting then to inquire whether the ultrastructure of the clear cells might reveal some details which would provide conclusive evidence of their renal origin.

This is indeed the case, and the main cytological feature revealed by the study of 8 clear cell carcinomas of the human kidney will be briefly outlined here.

In the electron microscope the tumour cells appear clearly delimited, separated from the vascular stroma by a typical basal membrane, identical to the similar structure in the normal kidney tubule. But whereas in the optical microscope the cytoplasm of the clear cells appears empty, here it is filled with structural elements among which three are most conspicuous: mitochondria, heavy osmiophilic fat deposits and glycogen. The abundance of mitochondria is one of the main characters of these tumour cells. Many of them appear literally stuffed with these organelles and the presence of numerous microbodies indicates that an active multiplication of the chondrioma is taking place. In all probability the high amount of fatty material noticed long ago in the clear cells is related with this extraordinary aptitude of the clear cell to produce mitochondria. This fact has to be kept in mind because it is in itself a characteristic property of convoluted tubule cells.

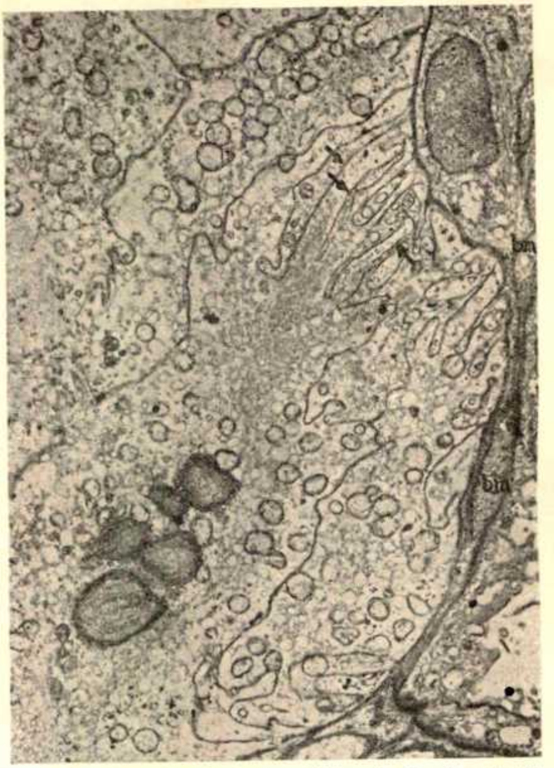

Fig. 1. Basal portion of a tumour cell showing the characteristic features of a convoluted tubule cell, especially smooth cytomembrane (arrows) inserted on the basal membrane (*bm*) (× 6,860)

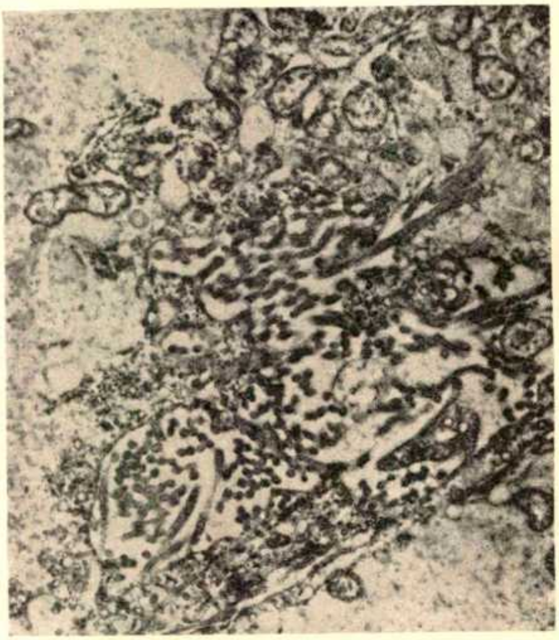

Fig. 2. Elements of brush border (central portion of the figure) belonging to a group of tumour cells (× 13,700)

But other and far more significant morphological details have come to light during these studies. In the first place the presence of smooth cytomembranes must be noticed. They form parallel sheets (Fig. 1) inserted perpendicularly upon the basal membrane. These formations exist in all cells where active exchange of liquid takes place such as in the choroid plexus, the ciliary epithelium and the submaxillary salivary gland[4]. They are also a very prominent constituent of the convoluted tubule cells. Furthermore, a number of the tumour cells exhibit a free apical surface provided with microvilli (Fig. 2) which are identical to the embryonic form of brush borders.

Here then are ultrastructural constituents of the clear cells in renal carcinomas which indicate clearly that these tumours arise from the epithelial cells of the convoluted tubule.

BIOLOGY

Collagenase Maceration of Kidney for Microdissection

THE traditional method of preparing kidney for microdissection is by maceration of formalin-fixed tissue with concentrated hydrochloric acid[1]. This method gives an excellent preparation of loosened nephrons and collecting tubules that can be disentangled and studied by microdissection. However, it suffers from the disadvantage that the acid treatment changes the nuclei so that they cannot be demonstrated in dissected preparations by the usual staining methods. A method of maceration that would allow nuclear staining after dissection would considerably widen the scope of the technique.

A variety of alternative macerating agents has been tried without success[2]. The present communication records the successful use of the collagenase of *Clostridium histolyticum* for maceration, permitting subsequent nuclear staining, of alcohol–acetic acid-fixed kidney.

In the course of the investigation, collagenase has been tested on fresh unfixed tissue and on tissue fixed with either alcohol, alcohol–acetic acid, acetone, acetone–acetic acid, saturated mercuric chloride, saturated picric acid, mercuric-dichromate (Zenker stock) or formol saline. Phosphate and borate buffers have been compared as diluents for collagenase; formol saline and 1 per cent acetic acid have each been tried as final fixatives for the macerated tissue; and the pretreatment of tissue slices with 6 *M* urea[3] has been tested. It has been confirmed that it is not possible to use collagenase for formalin-fixed tissue. Formalin alters the collagen substrate so that it is no longer susceptible to collagenase[4,5]. Alcohol-fixation does not inhibit the activity of collagenase, but the nephrons and collecting tubules are too brittle for dissection although good nuclear staining is possible. Acetone-fixation does not inhibit collagenase, the nephrons and collecting tubules are much easier to dissect and nuclear staining is not impaired. The addition of 25 per cent glacial acetic acid to either alcohol or acetone for fixation further improves the macerated tissue for microdissection.

Slices of alcohol–acetic acid-fixed kidney[6], about 1 mm. thick, are washed for 4 hr. in running water and are then immersed in phosphate buffer at *p*H 7 containing 0·25 mgm./ml. collagenase (Collagenase *ABC* Form II obtained from Agricultural Biochemicals Corporation, New York) and 0·1 mgm./ml. chloramphenicol. After 24 hr. at 37° C. the macerated tissue is transferred to formol saline. After microdissection, portions of nephron or collecting tubule that require staining are mounted on a slide under a coverslip and stained by drawing Mayer's hæmatoxylin through with blotting paper. After a few minutes the stain is rinsed away with Scott's tapwater and the nuclei are clearly stained in pale cytoplasm.

Although collagenase-macerated material is not so easy to dissect as acid-macerated tissue, the method, by allowing nuclear staining, yields valuable information not otherwise obtainable.

Culture of Human Leucocytes on the Chorio-allantoic Membrane of the Chick

A NEW technique has been developed for the culture of human leucocytes and other cells.

Suspensions of cells of the 'buffy coat' of heparinized human blood were introduced under sterile conditions into diffusion chambers consisting of two sheets of membrane filter ('Oxoid'), 2 cm. in diameter, cemented to a polystyrene ring. The inoculated chamber was sealed and dropped on to the chorio-allantoic membrane of the seven-day chick embryo through a slot in the egg-shell. Eggs were incubated at about 39° C. Cultures were examined at intervals to determine the state of the cells. After removal from the egg the filter disks were cut free from the polystyrene ring, placed on slides and stained with acetic orcein.

After two days of incubation many macrophage-like cells were present on the inside of both upper and lower disks of the chamber, but primarily on the upper disk. The fluid in the chamber contained mostly small lymphocytes and polymorphonuclear leucocytes which were also found on the bottom disk but apparently not attached. Present on the bottom disk was also a considerable number of large mononuclear cells which appeared to be attached to the membrane filter.

Cell divisions were first observed after four or five days of incubation and only in cells which seemed to be of the large mononuclear class. Divisions were observed in isolated cells (Fig. 1*a*) as well as in cells which were part of a group. Dividing cells were found only on the inside of the bottom disk of the chamber, that is, on the membrane filter which was in direct contact with the chorio-allantoic membrane of the chick. At five days most of the cells on the upper disk of the chamber were dead while the fluid in the chamber still contained healthy looking small lymphocytes and polymorphonuclear leucocytes. No human erythrocytes were left by this time. Chick cells were effectively excluded from the inside of the chamber.

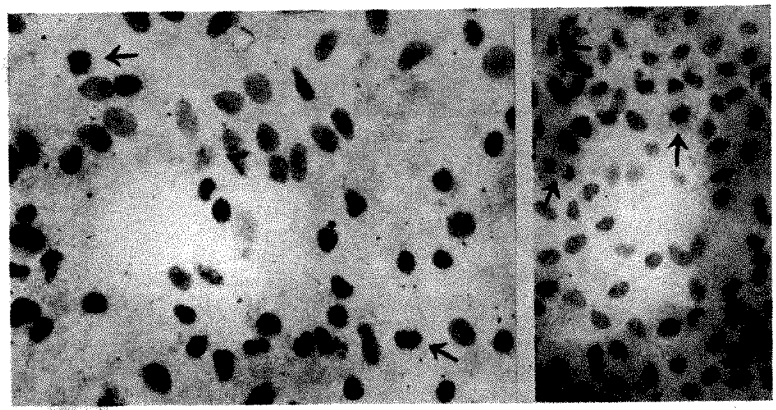

Fig. 1. Human leucocyte cultures. Arrows point to dividing cells. *a*, 7 days old; *b*, 14 days old

By seven days the number of cells in division was substantially increased and the cells were, for the most part, assembled into a nearly continuous sheet, epithelioid in character.

At five, seven or eight days, chambers were transferred to a new host and examined five or six days later (twelve to fourteen days from the start of the cultures). At this time the only cell-type remaining was a large epithelioid-like mononuclear cell found exclusively on the bottom disk of the chamber; this cell was several times larger than uncultured blood monocytes. All small lymphocytes and polymorphonuclear leucocytes had disappeared from both fluid and disks of the chamber and no debris was present. The frequency of divisions was higher than before (Fig. 1*b*), that is, of the order of 2 per cent.

Human foreskin fibroblasts and some embryo chick cells, cultured by the method reported above, also have yielded promising results. The technique may prove particularly useful for culturing cells which are ordinarily refractory to primary *in vitro* cultivation.

This work, part of a programme supported by the U.S. National Institutes of Health (*RG*. 5804), was done while I was Special Research Fellow (*CF*4028–*C*2) of the U.S. National Cancer Institute, on leave from the Department of Biology, Massachusetts Institute of Technology.

Decomposition of Humic Acid by Fungi

ALTHOUGH there have been a number of publications dealing with the utilization of humic acid by microorganisms, these papers have, at the most, reported that some humic acid preparations may serve as a source of nitrogen[1,2]. No convincing evidence appears to have been published concerning the destruction or utilization of the non-nitrogenous portion of the humic acid.

As the result of a prolonged series of percolation experiments, we have isolated a number of organisms capable of decomposing humic acid. Of these the two most active are fungi and have been provisionally referred to the genera *Spicaria* and *Polystictus*. After successful tests had been completed with the presumed *Polystictus*, the Basidiomycetes, *Polystictus versicolor*, *Hypholoma fasciculare* and *Trametes rubescens*, were also tested and found to decompose the humic acid. We have previously[3] discussed the difficulties associated with investigations concerned with the microbiological utilization of humic acid, but in the work reported here it is considered that there is evidence of a genuine biological decomposition of the humic acid molecule.

The humic acid used was extracted from the B_1 horizon of a podzol soil from Delamere Forest, Cheshire, by means of 50 per cent v/v lactic acid. The extract was passed through an ion exchange column, precipitated with hydrochloric acid and then purified by dialysing, first against dilute hydrochloric acid and then distilled water. The humic acid was then dried *in vacuo* at 45° C. An analysis gave the following percentage composition: carbon 50, hydrogen 3·9, oxygen 38, nitrogen 0·4, methoxyl 1 and ash 1·5. The basic medium used throughout was the one on which the effect was first observed and may not be optimal. It contained dihydrogen potassium phosphate, 0·4; dipotassium hydrogen phosphate, 0·6; magnesium sulphate, 0·5; potassium chloride, 0·5; sucrose, 20 gm. per litre, with trace elements and Fries's vitamin solution added. 200 μgm. per litre of vitamin B_{12} was also included.

Growth of the active fungi on agar containing sufficient humic acid (0·12 per cent) to produce a dark brown medium gave a clear zone associated with the fungal mycelium. There was no evidence of any accumulation of the humic acid by the mycelium as had been observed previously[3] with fungi such as *Penicillium* spp. In Petri-dish culture complete clearing of the medium occurred with *Polystictus* in four weeks.

Quantitative studies have been carried out using soil perfusion columns and large-scale cultures in penicillin flasks. At the end of the experiment the humic acid remaining in the perfusate or medium respectively was recovered. In addition to this the soil or mycelium in each case was treated with warm 1 per cent potassium phosphate solution to remove all absorbed humic acid, since it is known that not only fungal mycelium[3] but also soil colloids[4] will absorb considerable quantities of humic acid. The two extracts were combined and the humic acid precipitated and removed for final purification, drying and weighing.

The soil percolation columns contained sterile soil and were inoculated with either a spore suspension of *Spicaria* or a mycelial suspension of *Polystictus*. The results of the recovery of humic acid after a period of eight weeks are given in Table 1 and are compared with a similarly treated uninoculated control column. It can be seen that a considerable loss of the humic acid has occurred in comparison with the control.

The penicillin flasks contained 500 ml. of medium, but with the addition of 0·25 per cent agar and 0·039 per cent humic acid. They were inoculated and incubated at 25° C. for six weeks. The loss of humic acid is shown in Table 2.

Table 1. RECOVERY OF HUMIC ACID FROM SOIL PERCOLATION COLUMNS AFTER EIGHT WEEKS

	Humic acid (mgm.)		Loss (per cent)
	Added	Extracted	
Control	81	77	4·9
Spicaria	66	44	33·3
Polystictus	77	44	42·8

Table 2. RECOVERY OF HUMIC ACID FROM PENICILLIN FLASK CULTURES AFTER EIGHT WEEKS

	Humic acid (mgm.)	
	Added	Recovered
Control	195	210
Spicaria	195	162
Polystictus	195	70

The possibility was considered that the humic acid may have been reduced to a leuco form which was not precipitated by acids. Tests showed that this was not so and in any event the strong oxidase activity of *Polystictus*[5] makes this possibility very remote.

The ability of Basidiomycetes to decolorize humic acid suggests a similarity to the bleaching effect on malt agar reported by Nobles[6] and Cartwright and Findlay[7]. The colour of malt agar is due to the caramelized carbohydrates and is therefore akin to saccharo-humic acid. Tests with saccaro-humic acid prepared from sucrose with hydrochloric acid have shown that this is also decomposed by *Spicaria* and *Polystictus*. However, this does not necessarily mean similarity in structure between the two humic acids in view of the ability of *Polystictus versicolor*[8] to decolorize a wide range of organic materials including organic dyes.

The work described in this communication was carried out as part of a project for the chemical and microbiological investigation of humus in soil, made possible by a grant from the Nuffield Foundation. Our thanks are also due to Dr. F. M. Dean for his help and advice on the chemical aspects of the work and to Miss D. S. Griffiths for technical assistance.

A Method for Characterizing *Pseudomonas solanacearum*

Pseudomonas solanacearum (E. F. Smith) is an important and widespread bacterial pathogen of economic plants in tropical and warm temperate zones[1]. It has been shown recently that the cells of *P. solanacearum* grown on an appropriate medium are intensively sudanophilic, due to the presence of massive inclusions of poly-β-hydroxybutyric acid[2,3]. Formation of the polymer is known to be a characteristic of certain saprophytic pseudomonads[2,4,5]. A further study was made to ascertain whether such a distinctive character could be diagnostic.

Plant pathogens from the genera *Xanthomonas*, *Pseudomonas*, *Agrobacterium*, *Erwinia*, and *Corynebacterium* were tested for production of a sudanophilic cell component by growing them on a peptone medium containing glucose, sucrose, or glycerol, then staining with sudan black *B*[6], followed by extraction of the dried cells in chloroform to confirm the presence of poly-β-hydroxybutyric acid[2]. The results are summarized in Table 1.

Table 1. DIFFERENTIATION OF SOME PLANT PATHOGENIC BACTERIA ON THE BASIS OF FORMATION OF POLY-β-HYDROXYBUTYRATE INCLUSIONS

Bacteria	Host plants	No. of cultures examined	Cells containing prominent sudanophilic inclusions (poly-β-hydroxy-butyric acid)
Pseudomonas	Numerous	63 strains (33 spp.)	−
*P. solanacearum**	Solanaceae Musaceae, etc.	43	+
P. caryophylli	Carnation (*Dianthus caryophylli*)	3	+
P. stizolobii	Clover (*Trifolium* spp.) and velvet bean (*Stizolobium deeringianum*)	2	+
P. marginata	*Gladiolus* spp.	4	+ (2/4)
P. viburni	*Viburnum* spp.	1	+
Erwinia†	Numerous	13 strains (4 spp.)	−
Corynebacterium‡	Numerous	13 strains (9 spp.)	−

* The collection of *P. solanacearum* included 22 strains from solanaceous hosts (9 from potato) and 9 strains from musaceous hosts.
† Including *E. carotovora* var. *atroseptica* (blackleg of potato).
‡ Including three strains of *C. sepedonicum* (ring rot in potato).
In addition, 44 strains from 18 species of *Xanthomonas* and 10 strains from 6 species of *Agrobacterium* were examined. Relatively small sudanophilic inclusions were found in five strains of *X. albilineans* and in one strain of *A. tumefaciens*. The concentration of poly-β-hydroxybutyric acid was about 1 per cent of the cell dry weight formed on 2 per cent sucrose/peptone medium. Sudanophilic inclusions were not observed in the other cultures of *Agrobacterium* or *Xanthomonas*.

The 43 cultures of *P. solanacearum* were of wide geographical distribution and included strains from Brazil, Central America, southern United States, Israel, Cyprus, Southern Rhodesia, Uganda, Kenya, and Mauritius, as well as isolates from seed potatoes imported in 1959 from Egypt into Scotland and Sweden. The morphology and consistency of colonies of *P. solanacearum* on solid medium are known to be correlated with virulence in solanaceous hosts[7]; this collection included those which were predominantly opaque and fluidal (virulent), and also those which were exclusively translucent and non-fluidal (avirulent or reduced virulence), but production of the polymer was characteristic of all strains of the pathogen. In stained preparations of fluidal and non-fluidal colonies grown on the sucrose/peptone medium defined below, it was observed that cells from the former colony type stained more uniformly with sudan black *B* than non-fluidal cells. Two strains of *P. solanacearum*, *F*2 from tomato and *RE* from banana, showing in culture a clearly defined, apparently irreversible, change in colony morphology from fluidal (smooth) to non-fluidal (rough), were examined in order to correlate colony morphology and virulence with amount of poly-β-hydroxybutyric acid. The difference in intensity of staining with sudan black *B* was reflected in the quantity of polymer extracted from the cells (Table 2). Strain *RE* had previously been shown to be virulent in the fluidal form for banana and avirulent in the non-fluidal form. The same result was obtained for strain *F*2 in tomato[8,9].

Table 2. Correlation between Colonial Morphology and Poly-β-hydroxybutyric Acid Content in *Pseudomonas solanacearum*

Strain	Colony type	Fluidal (smooth)			Non-fluidal (rough)		
	Age of cultures (hr.)	Cell dry weight (mgm./plate)	Polymer (mgm./plate)	Percentage polymer in cell (dry weight)	Cell dry weight (mgm./plate)	Polymer (mgm./plate)	Percentage polymer in cell (dry weight)
F2 (from tomato)	24	16·3	3·3	20·2	23·0	3·0	13·0
	48	40·0	14·3	35·7	29·5	8·5	28·8
	72	40·7	19·3	47·4	30·5	8·8	28·9
RE (from banana)	36	17·3	4·0	23·1	21·0	3·3	15·7
	60	32·8	13 0	39·6	28·3	7·5	26·5
	84	37·1	18 0	48·5	28 8	7·0	24·3

Poly-β-hydroxybutyric acid was extracted with chloroform from the acetone-dried cells obtained from the surface of three or four 20-ml. quantities of solid medium in 9 cm. diameter Petri dishes inoculated over the whole surface. Incubation temperature, 30° C. Concentration of sucrose in medium, about 20 mgm./ml. (see text for complete composition).

The following medium was found to be satisfactory for detection of poly-β-hydroxybutyric acid and observation of colony variants in *P. solanacearum* (amounts in gm./litre of distilled water): sucrose (B.D.H., Ltd., laboratory reagent), 20·0; peptone (Oxo, Ltd., London), 5·0; dipotassium hydrogen phosphate, 0·5; crystalline magnesium sulphate, 0·25; agar powder (Davis), 20·0, *p*H adjusted to 7·2–7·4 with 40 per cent sodium hydroxide, autoclaved at 15 lb. pressure for 20 min.

In systematic bacteriology detection of poly-β-hydroxybutyric acid has proved to be a valuable ancillary test; in plant pathology there may also be applications. The milky exudate from the infected vascular bundles of potato, tomato, and banana, from which almost pure cultures of *P. solanacearum* have since been obtained, has been shown to be intensely sudanophilic. The technique may prove useful, for example, in differentiating in plant tissue the three bacterial pathogens of potato: *P. solanacearum* causing brown rot, *Erwinia carotovora* var. *atroseptica* causing blackleg, and *Corynebacterium sepedonicum* causing ring rot, and possibly in the field diagnosis of other diseases.

Previous work has shown that poly-β-hydroxybutyrate inclusions are not formed in representative species of several genera of the Enterobacteriaceae, to which in the present work the genus *Erwinia* is added[3,10]. The absence of the polymer from all but one strain of one species of *Agrobacterium* contrasts with *Rhizobium*, in which massive inclusions are formed both in culture and in the bacteroids of root nodules[4,5].

I am grateful to Dr. W. J. Dowson, Botany School, Cambridge, for the opportunity to examine the bacteria maintained in his laboratory, and for his advice and encouragement. Many of the bacteria examined were obtained through the courtesy of Mr. R. A. Lelliott, curator of the National Collection of Plant Pathogenic Bacteria, Plant Pathology Laboratory, Harpenden.

True's Beaked Whale from the South-East Coast of South Africa

Mesoplodon mirus True, True's beaked whale, is known from fourteen stranded specimens from the shores of the North Atlantic, the most northerly specimen being from the Outer Hebrides and the most southerly from Florida[1]. On May 21, 1959, a 17 ft. 6 in. beaked whale was washed up at Wilderness, 170 miles eastwards along the coast from Cape Agulhas, the southernmost tip of Africa. The skeleton of this whale was saved from the axes of the health authority's disposal squad by Mr. B. L. Cairncross, a local naturalist, and presented to the South African Museum. This whale proves to be an adult male True's whale. Dr. F. C. Fraser has kindly compared photographs of this specimen with the example of True's whale in the British Museum (Natural History), and confirms this identification, stating, however, that the lower jaw of the South African specimen appears deeper and more massive than the British Museum example.

Moore and Wood[1] have regarded this species as primarily a western Atlantic species, occurring north of latitude 35° N., and consider the single Florida specimen (latitude 29° 28′ N.) reported by them as probably a stray carried southward of its normal range by the south-flowing current inshore of the Gulf Stream. The finding of the present specimen in the Indian Ocean greatly extends the range of the species, possibly indicating a southern variety. It also shows, however, that the beaked whales are so little known, particularly in areas where coast lines are very poorly covered for strandings as is the case over most of the Indian Ocean, that any generalizing as to distribution is really guesswork at present.

This specimen will be fully described and figured elsewhere.

A Bivalve Gastropod

In *Nature* of March 12, p. 749, Drs. L. R. Cox and W. J. Rees reviewed a paper by the Japanese authors Kawaguti and Baba on a bivalved gastropod they had described under the generic name *Tamanovalva*. I should like to put on record a further occurrence of this remarkable group of molluscs. A single left valve (now in the Stanford University Collection, California) of what is probably a new species, with the characteristic spiral nucleus and central adductor muscle scar, was collected on Espiritu Santo Island, near La Paz, Gulf of California, in beach drift, on November 1, 1959.

The earliest generic name for this group of bivalved gastropods may prove to be *Berthelinia* Crosse, 1875 (*Journal de Conchyliologie*, vol. 23, p. 79), the type species of which, *B. elegans*, is from the Eocene of France. Specimens in the Paleontology Museum, University of California, have been available to me for study. I can see no significant differences in the shells between *Berthelinia* and the Recent forms, *Tamanovalva* from Japan and *Edenttellina* from Australia (until recently the latter had been assumed to belong to the Pelecypoda). That this opisthobranch gastropod group should have originated in the Paris Basin during Eocene time is not implausible, for many other molluscan groups now having a limited distribution in the Pacific Ocean flourished there during the early Tertiary. Whatever generic name is eventually accepted for these bivalved gastropods, the range of the group seems to extend back in time at least to mid-Eocene and in the modern seas from Japan to south-eastern Australia and to tropical West America.

Developments in the Propagation of Clones of *Hevea brasiliensis* by Cuttings

Clones of *Hevea brasiliensis* are normally bud-grafted on seedling rootstocks. In an attempt to overcome the disadvantages inherent in this practice, the Rubber Research Institute of Malaya is conducting an investigation of methods of establishing clones as trees growing on their own roots. Encouraging results are being obtained by rooting leafy clonal cuttings under special conditions which include the application of water as a mist spray.

Two clones recommended for large-scale planting in Malaya, *PB* 86 and *GT* 1, are being rooted with up to 90 per cent success. Other less-widely distributed clones have rooted similarly, including some of the hybrids of *Hevea brasiliensis* and *H. benthamiana*. It is now possible to obtain sufficient clonal material to investigate the stock–scion relationships in *Hevea*, and to improve the accuracy of other botanical and nutritional experiments. Furthermore, should these self-rooted trees prove satisfactory in the plantation itself, the mist-spray propagation techniques will find large-scale commercial application—either in propagating high-yielding clones on their own roots, or in raising selected clonal rootstocks for panel- or crown-grafted clonal scions.

In common with many forest trees, cuttings from young seedlings of *Hevea brasiliensis* root readily, while those from buddings do not[1]. As the seedling ages so rooting ability declines, in rubber quite sharply[2]. Some progress in the production of uniform material was made by Wiersum[3], who by 'stumping' a young seedling (that is, by cutting it back very severely) and taking cuttings from the resulting sprouts obtained 40 rooted plants from one individual. McIndoe[4] also found that cuttings from the lower 3 ft. of seedling trees root readily and that this process can be repeated with the vegetative progeny. He hopes that this high-rooting capacity may persist, but the performance and secondary characteristics of such untested material are unknown and the method is limited to experimental use.

Levandowsky[5] first reported the rooting of commercial budded clones in some quantity by leafy cuttings. While still attached to the parent 'stump', each shoot was wounded by ringing the bark. Some days later these shoots were removed, together with the portion of callused tissue at their base, and inserted in the rooting medium under a continuous mist spray.

Experiments at this Institute designed to study the effect and interplay of the various factors have now shown that the ringing operation is unnecessary. A more important factor is the efficiency of atomization of the spray, accomplished by raising the pressure to 50 lb. per sq. in. and the use of special nozzles. The present procedure in propagating *Hevea* by leafy cuttings is as follows. Bud-wood stems are cut back to 30 in. above the graft union, and the shoots arising from the latent buds are used as cuttings. Shoots from the top of bud-wood stems have also rooted well, and with certain clones even leafy shoots from trees in tapping have been used with success. Cuttings are selected which have healthy, fully expanded and mature but not senescent leaves; the terminal bud must not be breaking into fresh growth. The source shoots are cut when about 15 in. long, the lower leaves removed and the shoots transported in polythene bags. In the propagation nursery their bases are trimmed to provide cuttings about 10 in. long. After immersion in water the coagulated latex at the cut end is peeled off and the basal inch dipped into 'Fermate' dust (kindly supplied by Messrs. E. I. Dupont de Nemours and Co., Inc.). The prepared cuttings are planted into beds 5 ft. wide containing a rooting medium, a 1 : 1 mixture by volume of sawdust and sand being suitable. Finely atomized water is applied through nozzles and switched off only at night or during rain. The beds are shaded to reduce the light intensity to about 50 per cent and are surrounded by a screen to prevent excessive drifting of the mist.

With some clones rooting begins after about 40 days, a number are less rapid in their rooting while in others there is a rapid deterioration of leaf condition accompanied by complete failure to root. When the roots are approximately 1 in. long the cuttings are planted into baskets containing John Innes Potting Compost No. 2 and placed at the sides of the rooting beds in the drift of the mist. After a further week the rooted plants are moved, and when sufficiently hardened and the roots well established, they are planted out.

Rooted cuttings of more than fifty clones have been produced and successfully planted, and their subsequent growth and rooting habit are being observed. An experiment to compare the growth of self-rooted clones with conventional bud-grafts on unselected seedlings stocks has been planted. Other related experiments are being planned.

Meanwhile attempts are being made to improve the rooting of other recommended clones. These include the production of source shoots in suitable condition for regenerative response, the use of growth regulating substances and other chemicals, and the determination of the optimal rooting environment.

Results of these studies will be published in due course.

ENTOMOLOGY

Wetting Properties of Insect Cuticle

THE idea has long been current[1] that the tanning of insect cuticle by quinones makes it more 'hydrofuge'. It is certainly true that dry tanned gelatin is less easily wetted with water than the untanned protein. But it is doubtful if such a statement is meaningful, applied to a water-saturated protein, whether it be tanned or not. A more useful form of this original suggestion may be: the tanning of insect cuticle lowers its adhesion to water.

Recent experiments on the permeability of insect cuticle to water[2,3] suggest that the waterproofing is especially efficient when the waxes on the surface of the integument are packed in a solid monolayer, with the long aliphatic chains (*XY*, Fig. 1) pointing away from the cuticle surface, and with the polar endings (*YY*)—which are primarily hydroxyl groups—at the surface. The cuticle surface forming the substrate for such an orientated monolayer is not a simple protein, but a tanned lipoprotein[4]; it therefore now appears that the substrate has high adhesion to the hydrophilic, rather than to the aliphatic, ends of the polar molecules. Stated in this form, it would seem that tanned lipoprotein has marked hydrophilic affinities in circumstances where it might select either the hydrophilic or the lipophilic ends of polar molecules—the reverse of the thesis implied in the paragraph above.

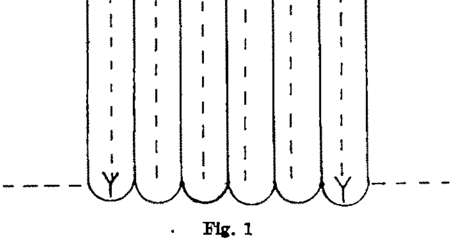

Fig. 1

Almost all substances, including solid paraffin wax, do become easier to wet after long exposure to water; but if the surface of a cockroach is washed in the surface of running water, whereby all its superficial unattached grease spreads away, the remaining surface is remarkably hydrofuge. From an assessment of the water-permeability, and of the permeability/temperature characteristics of such a washed animal, it would seem that only the orientated monolayer on its tanned cuticulin substrate remains behind[2], and that the extreme hydrofuge nature of this surface arises because such a monolayer will present an array of tightly packed —CH_3 groups (*XX*) to water placed on it—perhaps the surface with least adhesion for the water molecule. Recent experiments suggest that such a monolayer is likewise the structure over the surface of those hydrofuge areas of some aquatic insects, which can submerge for long periods, yet remain highly hydrofuge, as illustrated by their rapid shedding of water when they surface.

The evidence of recent studies on the permeability of these aquatic insects indicates, however, that they have an orientated monolayer of grease over their unwetted and over their readily wetted areas of surface as well. An examination of *Dytiscus* suggests that the cuticulin surface under the hydrofuge areas of grease is tanned, but that in the hydrophil areas of the natural cuticle, the underlying lipoprotein is not tanned. Now cuticulin and chorionin[5], which have large amounts of lipid condensed with protein, may well be expected to have a strong affinity for other lipoid materials, such as the aliphatic chains of polar greases—and much less affinity for hydroxyl groups. But the subsequent quinone tanning of a lipoprotein would appear to change this affinity, so that the surface then has high adhesion to the polar groups of the grease.

As a result of these observations and of physico-chemical experiments, the following thesis can now be advanced: a change in the affinity of cuticulin or of chorionin may be promoted by tanning it with quinones; as a result a polarized grease layer on such a surface will be reversed, and consequently the surface property of a greased lipoprotein will change from being exceptionally hydrophil to being extremely hydrofuge, through the tanning of the substrate.

Since residual grease films are difficult to eliminate, such a phenomenon may give rise to the suggestion contained in the first paragraph, and attributed to the property change of protein alone. However, the implications of such a mechanism are much more profound. It may not only explain the way in which the aquatic insect may differentiate its surface properties; but also it may, for example, provide a real explanation for unusual capillary activities which must take place in all insects. Thus, if a tube or sponge is composed of a lipoprotein with a reversed monolayer on its surface, capillary pressures in it will be very high, for the contact angle to water against the outwardly directed polar groups will be very small. On tanning, and change of the monolayer to normal orientation, the contact angle will become appreciably greater than 90°; little energy will therefore be required to empty such spaces. Such phenomena occur in the emptying of the tracheal system at eclosion[6] and at ecdysis[7], in the production of the air film of the plastron while submerged in water, and in the appearance of air in the aeroscopic sponges of egg-shell[8]; the authors quoted have repeatedly outlined the necessity for assuming that a mechanism is present which produces hydrofuge properties in a surface submerged in water, and have variously suggested that wax or its secretion, or the tanning of proteins, would prove essential to that unknown mechanism. The physico-chemical system now proposed would seem to satisfy these requirements and also to accommodate the associated evidence which has previously been described.

A full account of the experiments on which this suggestion is based, and of their probable implications for the physiological mechanisms of insects, will appear elsewhere.

Effect of Relative Humidity on Hatching and on Toxicity of Ovicides to Eggs of the Red Spider Mite, *Tetranychus telarius* (L.) (Acarina : Tetranychidae)

Some information is already available on the relationship between relative humidity and hatching of eggs of *Tetranychus telarius* (L.)[1]. However, the information is based on data compiled from broad ranges of relative humidity and therefore does not enable an exact picture of the relationship to be seen.

In connexion with biological and toxicological studies in this laboratory on eggs of *T. telarius* it has been found convenient to induce mites to lay eggs on glass slides. This has made it possible to make an accurate study of the effects of relative humidity. By holding eggs in a particular relative humidity at 23° C. for the whole incubation period, the degree of resistance to desiccation or drowning over the whole range of relative humidities has been obtained. Results are given in Fig. 1.

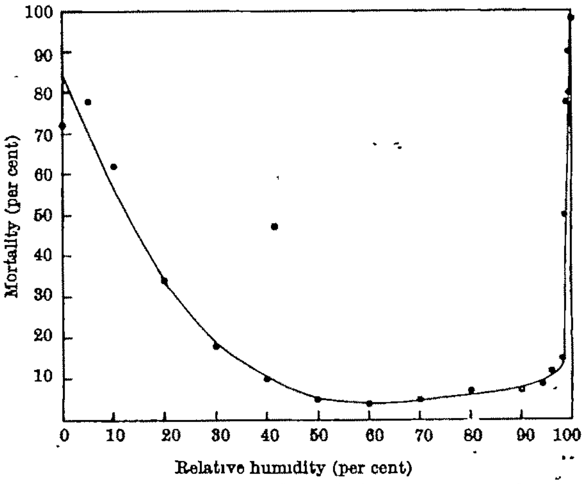

Fig. 1. Mortality of eggs of *T. telarius* in different relative humidities at 23° C.

With the red spider mite *Panonychus ulmi* (Koch), Beament[2] describes a change in the structure of the egg membrane which makes the egg 'waterproof' 6 hr. after it is laid. With *T. telarius* there appears to be no such complicating factor, the eggs having a certain resistance to desiccation and drowning from the moment of being laid.

Available information about the micro-climate on a leaf surface is unfortunately inconclusive. It can be assumed, however, that relative humidity can be high and in fact can reach saturation point. If such conditions of saturation or near saturation occurred for any prolonged period, it is clear that a high natural mortality of eggs could be expected.

Experiments with ovicides were carried out in relative humidities restricted to those which had little or no adverse effect on egg hatch. Freshly laid eggs of *T. telarius* were treated by dipping in ovicides (wettable powder formulations) and then incubated in different humidities at 23° C. The concentration of ovicide which produced 50 per cent mortality of eggs ($LC50$ = lethal concentration 50) was determined at each humidity. Regression lines of mortality against concentration, obtained at each humidity, were parallel. Several ovicides were tested and all showed a similar trend : a decrease in $LC50$ with an increase in relative humidity. Results obtained for one of them, 'Kelthane' (1,1-*bis*(*p*-chlorophenyl)-2,2,2-trichloroethanol), are given in Fig. 2.

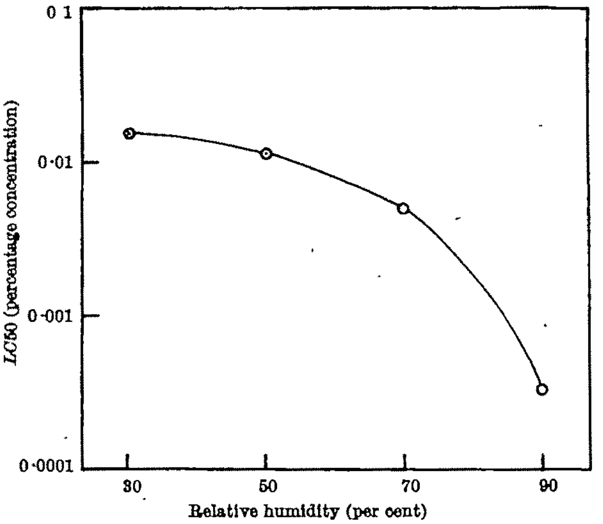

Fig. 2. Toxicity of 'Kelthane' to eggs of *T. telarius* incubated in different relative humidities. (An $LC50$ of 0·05 represents an application of ½ lb. active material per 100 gallons of water)

These results show that relative humidity must be considered as one of the significant factors affecting the performance of an ovicide.

Normal Susceptibility Levels of *Anopheles pharoensis* Theobald to DDT and Dieldrin

HOUSE spraying with residual insecticides, particularly with DDT and dieldrin, plays an important part in modern anti-malaria campaigns. The tolerance of malaria vectors to these toxicants is therefore of special interest. Assessments of the susceptibility of many different species of anopheline mosquitoes before and during spraying operations have been carried out in many parts of the world[1]. However, nothing seems to have been published on the normal resistance-level of *A. pharoensis*, a vector of malaria in several countries of Africa.

A number of tests have been carried out on this species in the village of Natsini, 10 km. outside the sprayed area of the Mass Malaria Control Campaign in Sokoto Province, Northern Nigeria. Wild females were obtained at night from a donkey-baited hut soon after they had engorged. In the following morning they were exposed for 1 hr. to filter papers impregnated with insecticide using the World Health Organization adult test method, a modification of the Busvine test[2,3]. The exposure-time was followed by a recovery-period of 24 hr., during which the mosquitoes were kept in unwaxed paper cups provided with cotton wool soaked in sugar solution. Then the results were read.

The temperature and humidity during the time of testing varied from 24° C. to 28·4° C., and 74 to 85 per cent respectively, and the range of temperature during the recovery-period was 20–30° C. The results obtained are shown in Table 1.

Table 1

Insecticide	Concentration (per cent)	No. of mosquitoes exposed	No. of mosquitoes dead	Mortality (per cent)
DDT	0·25	80	2	2
	0·5	240	30	12
	1·0	226	75	33
	2·0	307	218	71
	4·0	245	239	97
	4·0*	98	98	100
Control	—	163	0	0
Dieldrin	0·05	243	20	8
	0·1	288	100	35
	0·2	233	186	80
	0·4	227	223	98
Control	—	134	1	1

* Exposure time, 2 hr.

The median lethal concentrations (*LC*50) have been estimated graphically on the dosage-mortality lines drawn on logarithmic-probability paper. They were for DDT 1·5 and for dieldrin 0·14 per cent.

Susceptibility-levels, estimated for many different species of anopheline mosquitoes from untreated areas, have shown surprisingly little variation of the *LC*50[4]. It varies between 0·5 and 1·5 for DDT and between 0·05 and 0·15 per cent for dieldrin. The figures obtained in the present communication lie in the range of these variations and indicate a normal susceptibility of *A. pharoensis* to these insecticides.

Mortality and Viability of Insect Migrants High in the Air

ENTOMOLOGISTS have long been aware that vast numbers of insects are distributed up to thousands of feet in the air on any warm day[1]. The men who collected evidence of this assumed that the insects were alive[2–4]. However, the trapping methods they used killed most of the insects so that mortality and viability could not be assessed. Other entomologists have been less confident of the vitality of insects dispersing regularly by such flights, perhaps because of a belief that an ascent to, say, 5,000 ft. means a flight of many hours; this is not necessarily so[5]. Nevertheless, it is not generally accepted that this mode of transport is no more lethal than flight near the ground[6].

Insects have therefore been collected between 1,000 and 5,000 ft. at Cardington, Bedfordshire, England, with the kind co-operation of Mr. L. A. Speed and the staff of the Research and Development Establishment, to see what percentage of insects at these levels are alive and undamaged. The insects were caught in a vertical series of 6 nets, suspended from a balloon cable and opened for some hours between 09·00 and 16·00 hr. G.M.T. in June, July, August and September 1959. A mechanism opened the nets after ascent and closed them before descent[7].

Out of 1,610 insects caught, 1,571 (97 per cent) were alive and undamaged; 25 (2 per cent) were alive but damaged; 14 (1 per cent) were dead, when the nets were opened. Most of the damage to insects and some of the mortality were certainly caused by handling the nets. Mortality was probably also increased by the long time (up to 5 hr.) that some insects spent in the net after capture, exposed to the desiccating action of the wind. It may be assumed that the insects had, on average, completed half their aerial flight when they were caught, for the air almost clears of insects at night[1]. It can therefore be said with confidence that, of insects flying up to 1 mile high over southern England in mild summer weather, less than 2 per cent die in transit, except by predation or other means that leave no trace.

It is not possible to assess the viability of these insects quantitatively because it is often difficult or impossible to identify them at once and the pattern of reproductive behaviour is rarely known. However, some insects did reproduce, and living offspring were obtained from the following agricultural pests: cabbage aphid, *Brevicoryne brassicae* L.; peach-potato aphid, *Myzus persicae* Sulz.; bean aphid, *Aphis fabae* Scop.; frit fly, *Oscinella frit* L.; hessian fly group, *Mayetiola* sp., possibly *destructor* Say.

Many other insects, not yet identified, also reproduced successfully. Although not the smallest of insects, these include some of the most fragile. This seems to establish the viability of high-level migrants beyond reasonable doubt.

GENETICS

Homeostasis of the Sex Ratio in *Drosophila*

The ability of 150 larvæ to emerge as adults under 6 different temperature regimes for 3 inbred lines, their hybrids and the F_2 generation has been studied in *Drosophila melanogaster*[1]. This work revealed that interactions between genotype and environment were smallest in the F_1 generation and largest in the inbred lines. The F_1's therefore show a higher degree of stability or homeostasis than the inbred lines. The F_2 gave a genotype × environment interaction intermediate between the F_1 and the inbred lines, as might intuitively be expected because of segregation in the F_2.

The temperature regimes were 15° C., 24° C. for 8 hr. and 15° C. for 16 hr., 24° C., 24° C. for 8 hr. and 31° C. for 16 hr., 31° C., and 31° C. for 16 hr. and 15° C. for 8 hr. At 10 a.m. and 6 p.m., the replicates under the fluctuating temperatures were changed from one temperature to the other, so that the 16-hr. period represented the night and the 8-hr. period the day. The three inbred lines were Oregon (*OR*) and Sacramento (*SAC*), which were highly inbred by sib-mating, and Bikini (*BIK*), which has been mass-inbred since 1947. The *BIK* mass-inbred line was almost equivalent in homeostatic ability to the F_1 hybrids. This is perhaps because mass inbreeding permits the unconscious selection of heterozygotes more readily than under sib-mating.

While the data were being collected, sex ratios were noted throughout, and only recently have these been analysed. In Table 1, the percentage of females for each inbred line, F_1, and F_2, is given with a heterogeneity χ^2_5 testing the heterogeneity of the 2 × 6 contingency tables made up of the two sexes and the six temperature regimes.

Table 1. Percentage of Females and Heterogeneity χ^2 Tests

Inbreds	Females (per cent)	χ^2_5 for heterogeneity	Probability
OR	45·25	29·99	$P < 0·001$
SAC	48·97	9·42	$0·05 < P < 0·1$
BIK	50·41	2·15	$P > 0·9$
F_1's			
OR × *SAC*	51·88	9·00	$0·1 < P < 0·2$
SAC × *OR*	50·68	1·26	$P > 0·8$
BIK × *OR*	52·47	7·39	$0·1 < P < 0·2$
OR × *BIK*	51·80	3·50	$0·5 < P < 0·7$
BIK × *SAC*	51·91	5·62	$0·3 < P < 0·5$
SAC × *BIK*	52·38	1·18	$P > 0·9$
F_2's			
OR × *SAC*	52·51	12·55	$0·02 < P < 0·05$
SAC × *OR*	50·95	4·62	$0·3 < P < 0·5$
BIK × *OR*	51·37	11·29	$0·02 < P < 0·05$
OR × *BIK*	54·30	5·59	$0·3 < P < 0·5$
BIK × *SAC*	51·36	6·22	$0·2 < P < 0·3$
SAC × *BIK*	51·74	7·65	$0·1 < P < 0·2$

The *OR* and *SAC* inbred lines, which were inbred by sib-mating, were deficient in females and were relatively heterogeneous between temperatures, whereas the *BIK* mass inbred line gave 50·41 per cent females with no significant heterogeneity. Usually in *Drosophila* somewhat more females than males are expected[2], hence the *BIK* line is closer to the normal sex ratio than the *OR* and *SAC* lines. Furthermore, the *BIK* line showed no significant heterogeneity between temperatures, which again suggests its greater homeostatic ability compared with the *OR* and *SAC* lines.

All the F_1 crosses gave about 51 per cent females with no significant heterogeneity, thus demonstrating their superior homeostatic ability. The F_2's showed an excess of females, but with rather more heterogeneity than for the F_1 data, but less than the inbred lines. Similarly, as pointed out earlier, the smallest genotype × environmental interaction was obtained for the F_1, the largest for the inbred lines, and the F_2 interaction occupied a position intermediate between the F_1 and the inbred lines. Hence it may be said that the sex ratio data in this experiment agree with the magnitude of the genotype × environmental interactions observed. The behaviour of the sex ratio in the various inbred lines and crosses over the six temperature regimes therefore agrees with recent theories on the possible relationship of homeostasis and heterozygosity[3]. It must of course be emphasized that homeostasis and heterozygosity are not necessarily related in all situations[4].

In order to explain the deficiency of females in the *OR* and *SAC* inbred lines, it may be postulated that the homozygous genes of the *XX* females depress the viability of the lines somewhat more than the hemizygous genes of the *XY* males. The F_1's between these inbred lines gave considerably more flies than the inbred lines[1], and as about 51 per cent females were produced in the F_1 compared with 46 per cent in the inbred lines, the increase is made up of rather more females than males. Possibly this occurs because the F_1 females are heterozygous for the *X* chromosome, whereas the F_1 males are hemizygous.

If heterozygosity is related to homeostasis or stability, as occurs in many situations[3], then it is possible that the *XX* females would exhibit a greater degree of homeostasis than the *XY* males. To test this, the significance of genotype × environmental interactions was tested for each sex separately for the inbred lines, and the F_1 and F_2 generations. However, there was no suggestion of any difference between sexes. Hence it may be said that within the limits of accuracy of the data, there is no difference in homeostatic ability between the sexes. Consequently the *X* chromosome may not be of great importance in determining homeostatic ability, unless the *Y* chromosome in the males has an effect similar to an *X* chromosome.

Genetic Basis of Two Melanin Inhibitors in *Drosophila melanogaster*

Mutants such as ebony (*e*) and black (*b*) in *Drosophila* increase the melanin content of the integument of the adult fly. The ability of inbred and mass-bred larvæ of the genotypes $e''e''$, $e''+$, and $++$ to survive under various concentrations of the two melanin inhibitors phenyl-thio-carbamide and silver nitrate mixed in the food will be discussed briefly here, but complete details with additional information will be presented elsewhere.

Phenyl-thio-carbamide is an organic sulphur compound which inhibits melanin formation by combining with copper ions, which are necessary for the action of the enzyme, tyrosinase[1]. The inhibitory action of silver nitrate, a heavy-metal compound, is presumably due to its interaction with the enzyme itself[1]. In the presence of sub-lethal doses of silver nitrate, flies are bleached to a yellow-white colour[2] and are often greatly reduced in size, but in the presence of sub-lethal doses of phenyl-thio-carbamide the flies are phenotypically unchanged except that some flies are slightly reduced in size.

Various concentrations of silver nitrate and phenyl-thio-carbamide were added to the medium on which larvæ not more than 12 hr. old were placed. The number of larvæ emerging as adults was recorded for mass bred $e''e''$, $e''+$ and $++$ genotypes (e'' = ebony″, $+$ = Oregon stock). Inbred lines of the same three genotypes were also tested. The inbred lines were produced by single pair mating individuals heterozygous for e'' for 17 consecutive generations. The ebony and wild-type homozygotes were then selected from the segregants of the seventeenth generation. Hence the three inbred lines should differ from each other genetically in the region of the ebony locus, but the remainder of the chromosomes ought to be almost identical genetically and nearly homozygous. In Table 1, some results are presented. Each entry in the table represents the number of adult flies emerging from 100 larvæ (4 replicates of 25 larvæ).

Table 1. NUMBER OF ADULT FLIES EMERGING FROM 100 LARVÆ

Treatment	Mass bred $++$	Mass bred $e''+$	Mass bred $e''e''$	Inbred $++$	Inbred $e''+$	Inbred $e''e''$
Control	89	95	91	87	91	86
0·25 per cent $AgNO_3$	16	22	42	77	88	89
0·30 per cent $AgNO_3$	—	—	2	—	—	2
0·02 per cent P.T.C.	81	87	84	77	86	81
0·03 per cent P.T.C.	40	36	30	5	7	7
0·04 per cent P.T.C.	32	19	—	—	—	—
0·08 per cent P.T.C.	9	19	—	—	—	—
0·25 per cent $AgNO_3$ + 0·02 per cent P.T.C.	35	37	22	48	6	35
0·30 per cent $AgNO_3$ + 0·03 per cent P.T.C.	100	68	94	100	87	96

$AgNO_3$, silver nitrate; P.T.C., phenyl-thio-carbamide.

Considering first the mass-bred genotypes we see that silver nitrate is most lethal to $++$ flies and phenyl-thio-carbamide to $e''e''$ flies. The two inhibitors are therefore opposite in their action. Mixtures of the two chemicals in the medium might therefore lead to $e''+$ flies emerging at higher concentrations than the two homozygotes. The table shows the results of two such tests. For 0·30 per cent silver nitrate + 0·03 per cent phenyl-thio-carbamide negative heterosis was observed. In fact, no mixture of silver nitrate and phenyl-thio-carbamide produced positive heterosis. Hence the two inhibitors appear to be complementary in their action on the heterozygote so that its viability is depressed most. Negative heterosis of this magnitude, where both the homozygotes survive, with very few or no heterozygotes, has evolutionary possibilities in the creation of isolating mechanisms. This situation suggests that by a suitable adjustment of the composition of the food medium, both $e''e''$ and $++$ could co-exist, but would be unable to exchange genes and hence they could diverge. Conditions are therefore created by which sympatric speciation can occur.

Another effect is noticeable at high concentrations of phenyl-thio-carbamide. At both 0·04 and 0·08 per cent phenyl-thio-carbamide, 19 $e''+$ flies emerge. However, at 0·04 per cent, 32 $e''e''$ flies emerge and at 0·08 per cent, 9 emerge. Results not recorded here show that this trend is valid for intermediate phenyl-thio-carbamide concentrations. Hence we have a change in dominance according to concentration of phenyl-thio-carbamide. At 0·04 per cent, emergence appears to be correlated with the degree of melanization of the flies, but at 0·08 per cent there is no such correlation, and another system appears to have arisen which permits the development of heterosis.

Considerably more of the inbred flies survived on 0·25 per cent silver nitrate than mass-bred flies and silver nitrate is again most lethal to $++$ flies. This general increase in survival compared with the mass-bred flies is probably due to the inbreeding system used. As $e''+$ is not much darker than $++$, it may be supposed that there would be a tendency for the darkest $e''+$ flies to be selected so as to be sure they were $e''+$. Such a selection did, in fact, appear to take place as the $++$ line extracted at the seventeenth generation of inbreeding was visibly darker than the $++$ mass-bred strain. Hence, as the flies were being inbred, selection was also being carried out simultaneously for increased melanin production. In subsequent generations, the melanin content of all genotypes would be increased, as a result of selecting dark $e''+$ flies. In the mass-bred stocks, there was a correlation between melanin content and ability to emerge, and this relation appears to occur in the inbred stocks if it is assumed that selection has favoured more extreme melanization. Perhaps the melanins protect the developing fly by interacting with silver ions by a detoxification process, so that selection for increased pigment synthesis increases the tolerance of flies to silver ions with a resultant increase in survival value for all the inbred genotypes. With phenyl-thio-carbamide, therefore, we would expect fewer inbred flies to survive as there has been selection for increased melanization, for phenyl-thio-carbamide was most toxic to the mass-bred $e''e''$ flies. Table 1 shows that at 0·04 per cent phenyl-thio-carbamide no inbred flies emerged and at 0·03 per cent very few emerged. Hence, it is evident that the ebony locus is not the only locus affecting emergence under the two melanin inhibitors, but there is a substantial background of modifiers on which selection has acted. Finally, when silver nitrate and phenyl-thio-carbamide were mixed in the medium, negative heterosis was often observed. Many combinations did not show negative heterosis, but in no case did positive heterosis occur. Since inbreeding has only increased the general melanin-level, the occurrence of negative heterosis is to be expected in some cases.

Basic Chromosome Numbers in *Silene* and *Saponaria*

DURING the course of a chromosome survey of the north-west Indian angiosperms, I have found two new basic numbers in the Caryophyllaceae of the Panjab Plains.

Silene conoidea Linn. is a very common annual weed in this area. The species has been worked out from several selections and has revealed persistently

10 bivalents at metaphase 1 with perfectly normal meiosis. In view of the fact that more than 80 species of the genus *Silene*[1] possess the basic number 12, the present number ($n = 10$) is significant. There is, however, one species, *S. fortunei*[2], with $n = 15$. These facts suggest that, first, the presence of the haploid numbers like $n = 10$ and 15 in the genus indicates that the original basic number of this series is 5. *S. conoidea* is, therefore, tetraploid and *S. fortunei* is hexaploid. Hence, both these species are what may be called 'cryptic polyploids'. Here it may be of interest to mention that the present observations reveal that the grade of ploidy built on $x = 5$ is from $4x$ to $6x$, while on $x = 12$ it is from $2x$ to $16x$ [1].

Secondly, with the present observations the genus becomes dibasic ($x = 5$ and 12) and this at once raises the question about the probable constitution of $x = 12$, that is, whether it has been compounded from $x = 6$, or from $x = 5$ and 7. However, to date $x = 6$ and 7 have neither been discovered in any species of the genus, nor their presence surmised on even indirect grounds. In any event, the cytogenetical relationships between $n = 10$ in *S. conoidea* on one hand, and $n = 15$ in *S. fortunei* and species with $n = 12$ on the other, pose interesting problems. Furthermore, so far $x = 5$ has neither been found nor inferred on indirect grounds in any of the Silenoideae, but with the present observations one may be tempted to relegate $x = 15$, found in some genera of the subfamily, to only $x = 5$.

Lastly, in view of the overwhelming occurrence of $x = 12$ in the genus *Silene*, it is worthwhile to determine the biosystematical relationship of the species with $x = 5$, that is, whether the latter are genuine members of the genus.

Saponaria vaccaria Linn. is another very common annual weed. Several different samples of this species reveal the presence of $n = 15$ and $2n = 30$, which confirms the earlier findings of Mulligan[3]. Again this number is unique, since the prevailing situation in the genus is $n = 14$ [1]. Apparently, this genus also becomes dibasic with $n = 14$ and 15, and it is worthwhile to find out the cytogenetical relationship between the two numbers. Such a study would also reveal the true taxonomical relationship of the present taxon with the typical species of the genus *Saponaria*. Another important aspect is the biosystematic relationship of *S. vaccaria* with the genus *Vaccaria*. Such a study is needed, particularly because, first, the present results reveal that the genus *Vaccaria* exclusively possesses $n = 15$, and secondly, *S. vaccaria* has been in the past often treated taxonomically as a member of the genus *Vaccaria*.

The above aspects are being studied in detail and I shall be obliged for viable seeds of *Silene fortunei* and any species of *Saponaria*, *Vaccaria* and their allied genera.

I am grateful to Prof. P. N. Mehra for granting facilities and for his interest in the study and to Mr. Baldev Raj for technical help.

PSYCHOLOGY

The Brain as Regulator

There has been some debate whether the brain is determinate or probabilistic in its behaviour. As a contribution to this question, the following argument shows that from one point of view the determinate system is demonstrably of greater efficiency than the probabilistic. The physiologist may therefore expect to find that natural selection has made the brain as determinate as possible.

If the brain is regarded as basically a means to survival, then a necessary condition for survival is that against the (moderately well-defined) set of disturbances that threaten the organism's existence the brain must so respond that the outcome of the combined action of disturbance and response keeps the organism's essential variables within normal limits[1-3]. The brain must, in other words, act as a regulator, homeostatic in the general sense. The sequence of disturbances that comes to the organism can then often be treated (algebraically at least) as an information source (in Shannon's sense[4]) having an entropy, $H(D)$ say. Similarly, the sequence of responses will have an entropy $H(R)$, and so will the sequence of values at the essential variables, $H(E)$. It is necessary for survival (though not sufficient) that $H(E)$ be kept small.

The most interesting case is that in which, if the organism does nothing, *all* the changes at D produce changes at E (that is, the organism is passively buffeted to full degree). In this case $H_R(E) = H_R(D)$, and it then follows[2] that $H(E)$'s minimum is given by $H(D) + H_D(R) - H(R)$. So far as $H_D(R)$ is concerned, the expression will be least if $H_D(R) = 0$. This relation gives a necessary condition that the brain must satisfy if it is to have maximal efficiency in generalized homeostasis.

The meaning of $H_D(R) = 0$ is readily specified. Of any source A, $H(A) = 0$ implies that the Markov chain must be such that when it reaches equilibrium the transitions that still occur are determinate (that is, have probabilities all 0 or 1). $H_D(R) = 0$ implies that this tendency to determinateness must hold for each value of D.

Thus, if the brain is survival-promoting by acts of regulation, it has maximal efficiency (other things being equal) if, under constant external conditions, it tends towards the deterministic way of behaving.

A Differential Test of Arts/Science Aptitude

The increasing pressure of academic specialization raises the question of whether we can discover a test of differential aptitude for advanced work in arts and science subjects respectively. In a preliminary study, the performance of a large number of Cambridge undergraduates on a test of high-grade intelligence (*A.H.5*) has been analysed, with special reference to relative ability on the verbal, numerical and diagrammatic sections of the test[1,2]. Two differential scores were calculated as follows: 'Score *A*', diagrammatic minus numerical plus verbal; 'Score *B*', diagrammatic plus numerical minus verbal.

Two main results emerged. (*a*) If both differential scores were considered, a significant discrimination was found between arts and science students ($P =$ 0 001). (*b*) There were important differences in academic attainment between students with typical and atypical scores. The arts/science discrimination is shown in Table 1, where for reasons of convenience the distributions of scores have been divided into three groups: 'arts' scores, 'science' scores, and a 'neutral' group in which there was no pronounced discrimination. The group of arts students shown in Table 1 includes classicists, historians, linguists and students reading English. The group of science students includes mathematicians, physicists, engineers, botanists, zoologists and medical students. For reasons given below, it does not include students taking chemistry, biochemistry or metallurgy in Part 2 of the Tripos. With this one exception, students were classified in terms of the subject of the last Tripos taken, whether Part 1 or Part 2.

Table 1. DISCRIMINATION EFFECTED BY *A.H.*5 BETWEEN ARTS AND SCIENCE UNDERGRADUATES AT CAMBRIDGE

	'Arts' scores (per cent)	'Neutral' scores (per cent)	'Science' scores (per cent)
Arts students (n = 164)	66	28	6
Science students (n = 411)	7	45	48

From Table 1 it will be seen that the discrimination between arts and science students is very striking. The chances, for example, of a physicist having an 'arts' score, or a classicist having a 'science' score are as low as 1 in 20. The gist of the discrimination is as follows: arts students tend to score well on the verbal questions, and relatively poorly on the numerical and diagrammatic ones. The physical scientists (physicists, engineers, mathematicians) score well on the diagrammatic and numerical questions, and are relatively weak on the verbal ones. The biological scientists (botanists, zoologists and medical students) are relatively strong only on the diagrammatic questions. The only important exceptions are the students taking chemistry, biochemistry and metallurgy in Part 2 of the Tripos, who tend to be equally strong or weak on all three types of questions. Why this should be so is not at all clear.

Moreover, it was found that students with atypical scores (for example, a physicist with an 'arts' score) were significantly more likely than other students (*a*) to change subject in the middle of their undergraduate work, and (*b*) to gain a poor degree at the end of it. Further, those students with atypical scores who did change subject were four times as likely to choose a subject which was more rather than less concordant with their test results. (For all three differences, $P = 0{\cdot}001$.) On the strength of this evidence, we conclude that *A.H.*5 can validly be used as a test of arts/science aptitude, if given to undergraduates. The question then arises: Can *A.H.*5 validly be used at the age of sixteen, when the arts/science choice is crucial? Preliminary results suggest that such a use is feasible.

Samples of top-stream schoolboys have been tested at four schools, two public and two grammar. Each group tested was at a different stage of specialization, ranging from the highly specialized (some had never had a science lesson) to boys who had not specialized at all. It might be argued that the arts/science discrimination found among undergraduates was an effect of specialization rather than its underlying cause. If this were true, we should expect to find marked differences in the scatter of test scores both between schoolboys and undergraduates, and between specialized schoolboys and schoolboys who are unspecialized. Table 2 shows the standard deviations of both differential scores for five school samples, and for a representative sample of Cambridge undergraduates. It will be seen that the scatter of scores for all groups, unspecialized schoolboys and undergraduates alike, is remarkably similar. Further, Table 3 shows that the arts/science discrimination among partially specialized schoolboys is nearly as strong as that among a representative sample of undergraduates (including chemists, biochemists and metallurgists, and also the students reading geography, economics and law). Although promising, these results are no proper substitute for a follow-up study and should be viewed with caution.

Table 2. EFFECTS OF ACADEMIC SPECIALIZATION ON THE STANDARD DEVIATION OF DIFFERENTIAL SCORES IN SIX DIFFERENT SAMPLES

	Average age	N	'Score *A*'	'Score *B*'
School *A*	14·3	59	4 30	5·69
School *A*	17·1	58	3·83	5·77
School *B*	15 9	42	3·61	5 68
School *C*	16·0	50	4·29	5 18
School *D*	16·2	65	4·08	5·77
Cambridge	21·0	100	4·19	5·72

Table 3. ARTS/SCIENCE DISCRIMINATION AMONG SCHOOLBOYS COMPARED WITH THAT AMONG CAMBRIDGE UNDERGRADUATES

	'Arts' scores (per cent)	'Neutral' scores (per cent)	'Science' scores (per cent)
Schoolboys (n = 212)			
Arts	40	39	21
Science	10	38	52
Undergraduates (n = 603)			
Arts	55	33	12
Science	9	46	45

Letter Structure of the English Language

INFORMATION regarding the sequential dependencies among letters in the English language is of interest not only in connexion with linguistics and cryptography, but also because of its value for communication theory and for the psychology of language[1,2].

Only two sets of such data have hitherto been published. One[3] is based on the King James version of the Bible, and the other[4] on an unspecified source. As the source may be an important variable, we have analysed two samples of modern English. The first represents written language and comprises all the words in the editorial columns of *The Times* newspaper

for five successive days. The second sample, representing conversational language, is the text of the British Broadcasting Corporation's radio serial "Mrs. Dale's Diary", also for five successive days. In both cases names of persons and foreign place names were excluded.

The analysis was made by a National–Elliott 405 electronic computer at the G.P.O.'s London Electronic Agency for Pay and Statistics (*Leaps*). Two programmes have been written. One gives digram frequencies, counts being printed for all possible digrams; letter frequencies and a word count are obtained as by-products. The second programme gives trigram frequencies; the printed results give counts only for those trigrams occurring in the sample analysed.

Tables 1 and 2 show respectively the digram frequencies of the two samples. Copies of the trigram results are available from us. With the material now at hand, words can be generated which are either zero-, first-, second- or third-order approximations to either written or spoken English.

A Possible Fundamental in the Behaviour of Young Nidifugous Birds

THE great output of papers over the past few years on the phenomenon of imprinting has recently been reviewed by Hess[1] and this has been brought up to date by Thorpe[2].

Although it seems that imprinting may not necessarily be irreversible, and in fact may not be very different from other types of learning[2,3], it is still convenient to define it as "the process whereby certain juvenile birds become psychologically fixed upon the parent during the first very few days after hatching". Analyses of processes in young nidifugous birds covered by this broad definition have shown that imprinting may occur in response to a parent-object moving away from the juvenile or to various other visual stimuli including 'retinal flicker'[1,4,6], or to various acoustic stimuli[4,5].

All such analyses, however, utilize juveniles hatched in incubators or by the normal female not under detailed observation, that is, the analyses begin after the first possible stimulus-response period, the time of actual hatching, is over. In other words, incubator-raised juveniles may be 'incomplete' with respect to an appetitive behaviour-consummatory act complex involving the parent bird, and normally hatched birds will be 'complete' in this respect. Such a difference in experimental material may well result in differences in response; an unknown variable may have been operative.

Results suggesting this have been obtained in the course of work on eider ducklings (*Somateria mollissima*) in the Canadian arctic during the summers of 1958[7] and 1959[8]. Twelve eider ducklings imprinted to myself in varying degrees have been raised naturally in the field to at least one week old. After this some were raised on prepared food, some 'escaped', and some died. Most of the observed behaviour patterns have been checked by comparison with wild eiders of the same age at the same time and place. On the authority of Haldane[9], 20 randomly selected juveniles are regarded as enough for ethological statistical validity.

One of the most significant behaviour patterns observed is one which occurs immediately upon hatching. I propose to call this the 'brooding reflex' because it seems to be the mechanism whereby the newly hatched duckling orientates itself to the position of optimum warmth and mechanical protection beneath the female. It involves an active search by the duckling for a feeling of enclosure around the head or part of the head. In this way the duckling investigates its surroundings, the appetitive behaviour being a search for a space into which it can thrust its bill or head. Thus, a duckling a few seconds after hatching on my hand would actively follow my other hand once I had held its head between finger and thumb. A state of rest, or even of sleep, could be released in the ducklings merely by providing this contact stimulus on two sides of the head or bill. A higher degree of enclosure was even more significant, as long as the bird was warm and could breathe and wriggle. All the ducklings in my care showed this response to a constant degree, but more significant perhaps, is the fact that I found that I could release a similar quiescence in wild juveniles. To date, this response has been positive in every nidifugous juvenile I have handled including the imprinted eiders and three imprinted red-breasted mergansers (*Mergus serrator*), and varying numbers of wild juveniles of eider, old-squaw (*Clangula hyemalis*), Canada goose (*Branta canadensis*), ringed plover (*Charadrius hiaticula*), and purple sandpiper (*Erolia maritima*).

It seems that the 'brooding reflex' may be of widespread occurrence within the Anatidae, and even among nidifugous birds in general. Whether it is regarded as a conditioning immediately preceding imprinting, or as an integral part of the full imprinting process, it would appear to be a fundamental behaviour activity which has previously been overlooked.

Detailed results of these studies will be published in due course. The work was carried out with the financial support of a Carnegie Arctic Research Scholarship and field grants from the Banting Fund of the Arctic Institute of North America, and the physical assistance of Mr. C. W. Nicol, all of which I gratefully acknowledge.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, May 2

University College (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Prof. Z. M. Bacq (University of Liège) "The Enzymatic Inactivation of Adrenalin and Noradrenaline".*

British Society for the History of Science (in the Council Room (second floor) of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Prof. L. Pearce Williams. "Faraday and the Atomic Theory".

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5.30 p.m.—Mr. C. E. Tharratt: "Problems in the Launching of Black Knight", illustrated by lantern slides and a film.

University College (in the Embryology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. Jorge Dias (University of Lisbon): "The Makonde People: Conflicts of Culture".* (Further lecture on May 5.)

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Annual General Meeting followed by Dr. H. Baines: "The Use of Photography in Industry".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Sir Olaf Caroe, K.C.S.I., K.C.I.E.: "The Geography and Peoples of the Himalayan and Karakoram Frontiers".

Monday, May 2—Wednesday, May 4

Institute of Physics, Non-Destructive Testing Group (joint meeting with the Société Française de Métallurgie, at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1)—Conference on "Physical and Structural Aspects of Non-Destructive Testing of Metals".

Tuesday, May 3

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Teaching and Learning Machines" opened by Mr. C. E. G. Bailey.

Plastics Institute (at the Wellcome Building, 183–193 Euston Road, London, N.W.1), at 6.30 p.m.—Annual General Meeting, followed by a speaker from the Plastics Industry of the U.S.S.R.

Antiquarian Horological Society (at the Science Museum, South Kensington, London, S.W.7), at 7 p.m.—Annual General Meeting, followed by an illustrated talk on Mr. B. Hawkins' collection.

Tuesday, May 3—Wednesday, May 4

Society for Analytical Chemistry (in conjunction with the Iron and Steel Institute and the Institute of Metals, at Denison House, 296 Vauxhall Bridge Road, London, S.W.1)—Symposium on "The Determination of Gases in Metals".

Tuesday, May 3—Thursday, May 5

Iron and Steel Institute (at the Royal Commonwealth Society, Caxton Hall, and Church House, London)—Annual General Meeting, 1960.

Wednesday, May 4

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Dr. Ragnor Fjørtoft (Oslo): "The General Circulation of the Atmosphere" (Symons Memorial Lecture).

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. Philip Chantler: "Europe's Energetic Forecasting".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. L. Pearce Williams: "Michael Faraday and the Evolution of the Concept of Electric and Magnetic Fields".

Thursday, May 5

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. S. Ainsworth, Mr. Q. H. Gibson and Prof. F. J. W. Roughton, F.R.S.: "The Kinetics of the Reactions of Sheep Hæmoglobin with *Iso*cyanides"; Mr. R. H. Dadd: "Some Effects of Dietary Ascorbic Acid on Locusts".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. H. R. Hewer: "Expedition to North Rona, October 1959"; Mr. N. W. Simmonds: "Useful and Ornamental—a Miscellany of Tropical Plants".

Institute of Refrigeration (joint meeting with the Institution of Heating and Ventilating Engineers, at the Institute of Marine Engineers, The Memorial Building, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Mr. B. A. Phillimore and Mr. S. J. Jones: "The Demand for Cooling in the Modern Passenger Liner".

Institution of Electrical Engineers, Utilization Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. S. J. Emerson Annual Lecture on "Safety in the Utilization of Electricity".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 5.30 p.m.—Annual General Meeting.

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Prof. A. Butenandt: Adolf Windaus Memorial Lecture.

Friday, May 6

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Methods of Recording Measurements—Digital or Analogue" opened by Mr. W. J. Perkins.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Biophysicist (preferably with experience of protein structural studies) in the Immunology Department, to investigate the structure and interactions of antibodies and antigens—The Secretary, St. Mary's Hospital Medical School (University of London), Paddington, London, W.2 (May 4).

Senior Lecturer (graduate, with experience in either personnel management, industrial communications, or teacher training) in Psychology—The Registrar, Royal Technical College, Salford 5 (May 6).

Reader in Geophysics—The Secretary, The University, Exeter (May 7).

Senior Lecturer in Solid State Physics—The Secretary, The University, Exeter (May 7).

Senior Lecturer (with high qualifications and wide experience) in Physics, to teach to honours degree level; and an Assistant (Grade B) in Physics—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (May 7).

Senior Research Student in either Engineering or Chemical Engineering or Metallurgy—The Registrar, University College, Singleton Park, Swansea (May 7).

Lecturer or Assistant Lecturer (with an honours degree in philosophy) in Philosophy—The Registrar, University of Malaya in Kuala Lumpur, Pantai Valley, Kuala Lumpur (May 10).

Assistant in the Department of Zoology—The Secretary, The University, Edinburgh (May 14).

Lecturer (Grade II) in Physics; a Research Associate in Low Temperature Physics; and a Research Associate in Theoretical X-Ray Crystallography in the H. H. Wills Physical Laboratory—The Registrar, The University, Bristol 8 (May 14).

Lecturer (with special qualifications in physiological psychology) in Psychology—The Registrar, The University, Sheffield (May 14).

Senior Lecturer or Lecturer in Mathematical Logic—The Registrar, The University, Manchester 13 (May 14).

Staff Tutor in Science (Physical Scientist)—The Registrar, The University, Sheffield 10 (May 14).

Temporary Assistant Lecturer or Lecturer in Sociology or Social Anthropology—The Registrar, The University, Hull (May 14).

Demonstrator in Physical Chemistry—Head of the Physical Chemistry Laboratory, The University, South Parks Road, Oxford (May 15).

Fellow in Physical Chemistry—St. Catharine's College Planning Office, 42 Banbury Road, Oxford (May 15).

Lecturer and an Assistant Lecturer (with research experience in pure mathematics and preferably with qualifications in analysis) in Mathematics—The Registrar, University College of North Wales, Bangor, North Wales (May 16).

Lecturer (Grade II) in Pure Mathematics—The Registrar, The University, Bristol 8 (May 16).

Lecturer in Applied Mathematics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (May 16).

Regius Chair of Moral Philosophy in the University of Aberdeen—The Private Secretary, Secretary of State for Scotland, St. Andrew's House, Edinburgh 1 (May 20).

Lecturers (3) and Assistant Lecturers (3) in the Department of Chemistry—The Registrar, The University, Sheffield (May 21).

Lecturer in Physiology—The Secretary, The University, Aberdeen (May 23).

Assistant Lecturer in the Department of Applied Mathematics and Theoretical Physics—Secretary of the Appointments Committee of the Faculty of Mathematics, The Arts School, Bene't Street, Cambridge (May 25).

Student Demonstrator (graduate) in the Department of Botany, University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 25).

Assistant Lecturers (2) in Zoology—The Registrar (Room 22, O.R.B.), The University, Reading (May 28).

Lecturer or Assistant Lecturer (with special experience in food microbiology) in the Department of Microbiology—The Registrar (Room 22, O.R.B.), The University, Reading (May 28).

Senior Assistant Librarian (suitably qualified academically and professionally), to take charge of the Library of the Faculties of Agriculture and Engineering, University College of the West Indies, Trinidad—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 30).

Chair of Mathematics in the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, May 31).

Lecturer or Senior Lecturer in Genetics and Plant Breeding; an Assistant Lecturer in Botany; and a Demonstrator in Zoology—The Registrar, Wye College (University of London), near Ashford, Kent (May 31).

Lecturer (science graduate, with experience in bacteriology, immunology or virology, and in research methods) in Microbiology at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, May 31).

Professor of Mathematics or Applied Mathematics at the University of Natal, Durban, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, May 31).

Research Fellow (with a Ph.D. degree or equivalent experience) in the Chemistry Department, for fundamental work on compounds potentially useful in the paint industry—The Professor of Chemistry, The University, Hull (May 31).

Senior Research Fellow (graduate in agricultural chemistry, biochemistry or physiology, with some experience of research in animal nutrition) in Poultry Nutrition—The Secretary, University of Nottingham School of Agriculture, Sutton Bonington, near Loughborough (June 1).

Executive Assistant (with experience in administration and control of non-academic staff, and in writing and editing) in the School of Physics, University of Sydney, to assist the Head of the School in the administration of the School and the Nuclear Research Foundation, and to edit and write the major portion of the Foundation's publication *The Nucleus*—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1, and the Registrar, University of Sydney, Sydney, N.S.W., Australia (June 3).

Lecturer/Senior Lecturer in Biochemistry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 3).

Lecturer in the Department of Physics—Prof. P. M. S. Blackett, F.R.S., Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7 (June 14).

Lecturer or Senior Lecturer in Psychology at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 15).

Edwin Cuthbert Hall Chair of Middle Eastern Archæology in the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 30).

Senior Lecturer or Lecturer in Applied Chemistry at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, June 30).

Experimental Officer (at least 28, with a degree in engineering, H.N.C. or equivalent qualifications, and experience of research work) at the National Institute of Agricultural Engineering, to work in co-operation with the Department of Hop Research, Wye College (University of London) on engineering problems connected with the mechanization of hops and hop drying—The Secretary, National Institute of Agricultural Engineering, Silsoe, Beds.

Lecturer in Mathematics—The Registrar, Bradford Institute of Technology, Bradford 7.

Research Assistant (with a first- or second-class honours degree in biochemistry), to assist with investigations into disturbances of calcium metabolism—The Director, Metabolic Disturbances in Surgery Research Unit, The General Infirmary, Leeds.

Senior Lecturer or Lecturer in Bacteriology and Parasitology at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Solid State Scientists, Scientific Officers (with at least a first- or good second-class honours degree and preferably with post-graduate experience in solid state studies), in the Metallurgy Division, to study the basic mechanisms giving rise to the physical properties of certain nuclear ceramics in both single crystal and polycrystalline form—The Group Recruitment Officer (1639/34), U.K.A.E.A., Atomic Energy Research Establishment, Harwell, Didcot, Berks.

HUMAN PROBLEMS OF INNOVATION IN INDUSTRY

DURING the past two or three decades, there has been a quickening of technological change in British industry. Associated with this change, both as cause and effect, there has been a marked increase in the number of industrial scientists whose role is not merely to perform tests, answer specific practical questions, or evolve minor improvements, but also to innovate, to open up new possibilities whether of production or use. To an unprecedented extent, technical innovation is becoming a 'resource' of industrial firms, like the manual skill of operators or the administrative skill of managers.

This injection of a new element, this resort by firms to research and development as a continuing activity, calls for changes in the structure and method of management. The kind of management organization and practice, including relationships between different levels of management, which will work well when a business is running on an even keel, will not work where technical methods are rapidly changing.

A brief account by Honor Croome describes a study made by Tom Burns and G. M. Stalker between 1955 and 1957 in certain Scottish firms which entered a new business field involving rapid technological development*. It examines the strains which consequently arose in the field of management, and especially the difficulties which were encountered in acquiring the new resources of "Research and Development", and fitting a newly recruited or newly expanded research and development group into the managerial structure.

The firms were mostly those taking part in the scheme initiated by the Scottish Council (Development and Industry) to stimulate the growth of the electronics industry in Scotland. Behind the scheme, and bulking large in its founders' minds, was a particular war-time experience: that of the collaboration between the Telecommunications Research Centre, serving officers of the Royal Air Force and Air Staff officers.

The scheme was formally designed to bridge the gap between the users of electronic products—initially, the Service departments and the Ministry of Supply—and those firms which, although potential producers, had no adequate research team or laboratories and no experience in handling development contracts. One big firm, Ferranti, Ltd., of Edinburgh—which had special expertize in electronics and was the reason for choosing this rather than some other 'growing point' of technology for the experiment—agreed to perform the functions of intermediary, or 'staging point'.

The first contact is generally between the Scottish Council and the management of a particular firm; the initiative may come from either side. The firm is told about possibilities and procedures, and its management is invited to examine the Ferranti laboratory and possibly some Government research stations. There follows a discussion between its management, Ferranti, Ltd., the Scottish Council, and one of the Defence Ministries, with the view of picking a development contract which suits the firm's present activities, technical capacities, and future plans. A suitable contract is one which can be handled by the firm and Ferranti, Ltd., between them. When this is arranged, the new firm engages a number of design engineers, who then work alongside the Ferranti group attached to the contract. When the new team has sufficiently grasped the requirements, the special techniques, and the methods of co-operation involved, it carries on until the contract is fulfilled.

To the participating firms the main merit of the scheme lies in its efficacy as a pump-priming operation. The initial share of a development contract can justify recruiting a design team. By working alongside Ferranti's, that team can gain invaluable experience in appreciating the requirements, the special techniques and the appropriate methods of working together. The last phase, the one that really matters, is that in which this experience is used to exploit the potentialities of electronics in the firm's own sector of industry and its own markets. Such exploitation demands more than the technical designer's expertize. It calls for the appraisal of factors which lie outside his special function. Management has to consider the firm's productive resources; present and future market needs; the capital resources which might be required, and also the sources from which, and the conditions under which, these could be raised; the stresses which the finances, the employees, and the organization of the firm can bear. It has to assess the potentialities of the new techniques; the ability of the design team to evolve in time a product which can be manufactured; the abilities, too, of the draughtsmen, planning engineers, estimators, craftsmen, foremen, inspectors, salesmen and others. Wherever technical innovation is introduced as a 'resource', it affects every aspect of management and every manager throughout the firm; and in so doing it affects the relations of managers with one another.

It was found in the present case that, in the presence of rapid technical change and the strains which it imposes, two natural human reactions can be recognized and guarded against. One is the impulse to scurry back for safety to the 'mechanical' system, the authority of the chief and the book of rules. The other is to blame the personal defects and shortcomings of the individuals involved. Whether or not they contribute to the trouble, it has deeper causes.

These are negative prescriptions. Positive prescriptions must be differently interpreted in every firm. The first and most general requirement is that management should constantly re-examine what the firm is supposed to be doing, with the conscious aim of adapting operating methods and the structure of managerial relationships to their present task. If the task of the firm can be carried out by a number of people, each with a set of responsibilities and correspondingly limited liabilities, each occupying a well-established place in a pyramid of authority, such a system is economical and effective and has the great advantage of imposing less wear and tear, stress and uncertainty on individuals. But when the firm is tackling new tasks, commercial or technical, this system of differentiated routine functions is not satisfactory. Delimitations must be made fluid, and responsibilities must be elastically shared. Every effort must be made to encourage the sense of the business as a whole, with objectives and goals common to all its members, rather than a complex of separate 'jobs'. The stronger this sense, the more recourse there should be to 'lateral' consultation, which should be recognized and facilitated and not regarded as a mere semi-legitimate supplement to the 'vertical' channels of command.

---

* Department of Scientific and Industrial Research. Problems of Progress in Industry No. 5: Human Problems of Innovation. Based on a study of some Scottish firms by Tom Burns and G. M. Stalker. Pp. 36. (London: H.M. Stationery Office, 1960.) 2s. 6d. net.

Putting these prescriptions into effect is partly a matter of organization and partly of establishing a code of good manners expressing—whatever the level of formality or informality—a spirit of co-operation and appreciation rather than the desire to score or to assert prestige. The firm should regard the continuous, deliberate re-casting of its structure, the establishment of 'organic' relationships, and the maintenance of a social climate in which these can flourish, as no less important a part of the innovating process than the building of laboratories and the recruitment of scientists and technologists.

CANCER RESEARCH IN THE U.S.S.R.

Pathogenesis and Immunology of Tumours

Edited by G. V. Vygodchikov. Translated from the Russian by R. Crawford. Pp. viii+258. (London and New York: Pergamon Press, 1959.) 80*s*. net.

THIS volume consists of a collection of papers in honour of Prof. L. A. Zilber's sixtieth birthday and is in no sense a text-book. Indeed it reads more like the annual report of the British Empire Cancer Campaign except that it does not cover so wide a field. It is unfortunate that the publishers did not give the date of its publication in the U.S.S.R., but the bibliography makes it virtually certain that most of the articles were written in 1953. Part one deals with the pathogenesis of tumours, parts two and three with immunological studies and there is a short section on investigations with electron microscopy.

A virus ætiology is widely favoured in the U.S.S.R. and one of the most interesting articles is that of Timofeevskii and Benevolenskaia on tissue culture studies. It is claimed that the mammary tumour milk agent can be propagated in cultures of mouse tissues as well as those of other species. The authors favour the idea that malignant transformation *in vitro* is due to viral activity. The milk agent itself did not produce malignant change in their hands but is said to stimulate growth. They produce some evidence that methyl cholanthrene and the milk agent act synergically to produce malignant change. The article is critically written, and readers must bear in mind that it is seven years old. A very scholarly review on the viruses of fowl leukoses by V. A. Parnes is curiously included in the next section.

Zilber and his school are best known for their serological work. A technique much used by them is to sensitize guinea pigs against a tumour, to de-sensitize with normal tissue or other pertinent antigen and then to challenge with the homologous antigen. Points of interest concern the ability to absorb rabbit papilloma virus with rabbit red cells, leaving a preparation free of virus but containing other tissue components. V. A. Artamonova has exploited this to demonstrate antigenic differences between papillomata and the resulting carcinomata. The same author claims to have isolated proteins from carcinomata that will neutralize the papilloma virus. There is a short and interesting article on the antigenic properties of human amyloid by V. A. Parnes. There are articles dealing with the antigenic properties of human tumours, and tumours from mice, rats and birds. Generally they show the presence of antigenic components present in neoplastic tissues that are absent from normal tissues; different types of neoplasm share some components but have some peculiar to themselves. In their article on the specific antigens of malignant tumours in man Gorodilova and Shershulskaia claim that specific antigens may sometimes be demonstrated on the red cells of patients with cancer of the lung, stomach, mammary gland and ovary.

Unless inbred strains can be used, claims to demonstrate tumour specific antigens tend to be suspect. One naturally wonders how far Lysenko might be responsible for the Russians being slower than some Western investigators to realize this. Probably he had no such influence. It appears that they simply failed to realize the impact of genetic research until they read T. S. Hauschka's review in *Cancer Research*, in 1952. It is quoted several times in this book and D. M. Levina directs attention to the desirability of further work with inbred strains. When I heard Prof. Silber speak in Amsterdam last June he emphasized the need to distinguish between transplantation antigens and tumour specific antigens. He has abandoned his anaphylactic technique in favour of gel diffusion methods. Work with inbred strains in Britain and the United States is now beginning to reveal tumour-specific antigens, so a great deal of the Russian work with other types of material may prove to be substantially correct.

P. A. GORER

EDUCATION IN SOCIOLOGY

The Social Purposes of Education

By K. G. Collier. (International Library of Sociology and Social Reconstruction.) Pp. xv+236. (London: Routledge and Kegan Paul, Ltd.; New York: Humanities Press, 1959.) 21*s*. net.

IT is not easy to decide at what level to consider this book. The title and the series in which it appears lead one to hope for a sustained and distinctive contribution to our thinking about the social purposes of education. But the author seems to renounce this, saying that a comprehensive treatment would involve command of several academic disciplines and is probably beyond the compass of a single person. He says that he writes primarily for teachers and student teachers, and so we expect a book rather of simple exposition. Yet towards the end of his preface he re-states his aim as being "to articulate the relations between these disciplines". This is a task that would scarcely seem to be that of a near text-book. Then he immediately re-phrases this as being equivalent to a "search for criteria by which to judge educational methods". These two things, though related, are surely not the same. One begins to wonder what kind of book is intended.

The result is a work that has some good things in it, and that calls on a commendably wide background of reading, but that does not satisfy. The first three sections involve some economics, some sociology, some psychology and some discussion of 'values'. The last section, called "Educational Principles", is rather like a chapter from a sensibly progressive hand-book for teachers, and one feels that one is now at a different level of discourse. An attempt is made to link the earlier and the later sections, but in a very general way and without rigour.

Even if the purpose of the book were the modest one of starting students to think about the social purposes of education, one wonders how the author could attempt this without either more philosophical penetration or serious study of comparative education and societies. Philosophically, the book is conceived from within a very limited framework. There are many incidental signs of this, the oddest being the statement that science sprang from Christian sources, those of late medieval Christendom, a surely inadequate account of the history of scientific thinking in human history. Again, the good teacher's aim to show his pupils the truth as he sees it "without obliging them to choose his solution" is equated with the words of the Collect, "Make us love that which Thou does command". This is the kind of looseness which is allowed to pass too often in 'uplifting' writing about education. There is a great difference between commanding people to accept what you ordain (and to like it to boot) and leaving them free to make their own choice. There is the same lack of penetration in discussion of acceptance of the evils from which we suffer. These, we are told, may be accepted with a good grace when seen as coming from God, but are the soil of "envy, hatred and malice and all uncharitableness" when seen as the work of man. The author is thinking not of the material cause of suffering but of the frame of reference in which it is seen; but if he had thought of Islam and the "will of Allah" for a moment instead of his own beliefs he would have seen that this framework has a bearing on the readiness to remedy remediable suffering. When one thinks of the less-developed areas of the world, it seems terribly inadequate to say that the cause of suffering lies within oneself. Some, but indeed not all, suffering is an 'unalterable reality'.

This leads one to note the most surprising omission of all. How can one study the social purposes of education without considering different methods and systems of education in different social settings? Mr. Collier has a reference or two to such writers as Margaret Mead and Ruth Benedict, but one would have thought it indispensable to consider the role of the school in American social history or the social conception of education in the U.S.S.R. in our own times, or the social function of education in primitive societies and the impact of change on this, or Greek ideas about education seen in relation to society in fifth-century Greece; or at least some of these.

There is much material in this book that could have contributed either to a handbook for British teachers on the theme of the social setting of their work and the problems of 'socializing' the young through the school, or to a more sustained inquiry into the nature of the problem as such. But the book as it is is not quite one thing or the other, and it must be confessed that it leaves one disappointed.

H. L. ELVIN

MATHEMATICS AND THE CONDUCTION OF HEAT IN SOLIDS

Conduction of Heat in Solids
By Prof. H. S. Carslaw and Prof. J. C. Jaeger. Second edition. Pp. x+510. (Oxford: Clarendon Press; London: Oxford University Press, 1959.) 84s. net.

THE theory covered by this book has a long history stretching back to the classical work of Fourier. It has undergone various stages of development covered by the subjects of Fourier series and integrals, Fourier–Bessel series, Laplace transforms and more recently integral transforms generally. The present work, the second edition, replacing the edition of 1947, gives a very comprehensive treatment of the theory and provides "as complete account as possible of the exact solutions and soluble problems of the subject". That the account is complete is very evident to the reader, who may be tempted into asking if there is much point in taking the analysis so far as is done in some cases.

The first 300 pages are devoted to the theory based on Fourier series. This includes the linear flow of heat in infinite and semi-infinite solids of various simple shapes. It concludes with an important new chapter on change of state, showing clearly how far it is possible to go with exact solutions and when recourse must be had to numerical methods. Melting and solidification are treated, and the practical importance of the results in problems such as ice formation, solidification of castings and the cooling of igneous rocks is pointed out.

Three chapters are given to the use of the Laplace transform method. These cover both linear flow and problems on the sphere and the cylinder, and emphasis is placed upon problems which may be solved more easily by this method than by the classical method. A practical problem which yields nicely to a theoretical treatment is the heating of a buried electric cable. Both short-circuit heating and constant-current heating are treated. The theory of heat regenerators and heat exchangers is also developed via the Laplace transform method, and there is a section on the theory of systems for automatic temperature control. It is perhaps a pity that more space is not devoted to these two topics, considering their great importance in chemical engineering. But the large number of references given will lead the reader to a more extended treatment.

The last two chapters are in the nature of surveys. They give accounts of the use of integral transforms and the use of numerical methods. The former has been developed in recent years, notably by Sneddon and by Tranter, and a crucial property of the transformations is that in many cases they reduce the Laplace equation in two variables to an ordinary differential equation. The chapter on numerical methods is a short one showing how the equation of heat-flow may be converted approximately into a set of difference equations which may be solved numerically. There is also a brief section on the use of relaxation methods. It seems a pity that more space was not given to the use of numerical methods; for the limitations of exact solutions in practical problems are much in evidence throughout the book (for example, in the chapter on change of state), and a very powerful tool, namely the electronic computer, is now available for obtaining solutions to problems formerly beyond the range of the numerical analyst. In my opinion the analysis (in terms of symbols) of practical problems is sometimes carried too far, and it would almost certainly save much time in future if those concerned with heat-flow in practical problems were to make use of numerical methods at an earlier stage than has been customary in the past.

This book, more than ever, will continue to be the standard reference work in its field. It is to be noted that there are now more than 700 references. The beginner needing a guide to the vast literature on the subject, and the research worker who wishes to see how far exact analysis will take him in a particular case, will find it essential to consult "Carslaw and Jaeger". L. S. GODDARD

COGITO ERGO SUM

Symbolic Logic and Intelligent Machines

By Edmund C. Berkeley. Pp. v+203. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1959.) 52*s*. net.

EDMUND BERKELEY'S previous book, "Giant Brains or Machines that Think", and its sequel are well-known introductions to the field of digital computers. The present book seeks to infuse life into the more recondite subject of mathematical logic.

Designers of computing systems differ in their regard for symbolic logic, and in particular Boolean algebra, as a practical tool, but nevertheless any but the merest tyro should have at least a working knowledge of the discipline.

As an introduction to Boolean algebra this book can be recommended, even though I join issue with Berkeley over the merits of Boole's own "Laws of Thought". This recommendation is possible because the latter book, although most readable, was written with an eye to the formal logic of the schools rather than as a design tool for switching circuits.

The first six chapters of Berkeley's book deal with formal logic and its application to switching. The treatment is basically that of Shannon, but the illustrative examples are of a light-hearted nature which will appeal to the non-specialist.

The first contact with 'intelligent' machines occurs in Chapter 7, where readers are invited to agree that intelligence is "the ability to learn from experience, to acquire and retain knowledge, and to respond quickly and appropriately to new situations, thus resulting in success in the performance of tasks". This definition could be questioned from a number of points of view, but, at the level at which the book is written, it is probably as good as any.

Unfortunately, the robot the actions of which satisfy this criterion of intelligence does not appear in subsequent pages of the book, and the reader may well doubt that a hall light, a syllogism machine, or a decimal adder justifies any claim that an intelligent machine exists. It is only fair to say that the author realizes this and, on page 97, attempts to clarify his position.

The remainder of the book is devoted first to an explanation of the way in which Shannon introduced the notion of time into switching algebra, which is very clearly written, and finally to the programming of Newton's method for evaluating a square root on a hypothetical digital computer *Zac*. This last chapter is a complete *non sequitur* and it is difficult to see why it was included.

In his preface the author invites comments and corrections. Unfortunately the number of misprints is too numerous for detailed mention, but it is impossible not to remark on the unsatisfactory nature of the circuit drawings. Surely it is not too much to expect the use of ruler and compasses and the adoption of standard notations for relay coils, and for rectifiers (for example, on Fig. 11·1); the same modicum of care might also have avoided such confusing situations as those shown in Fig. 14·6, where five change-over switches have both their sides connected to earth.

A. D. BOOTH

BIOCHEMISTRY AND MEDICINE

Biochemistry in Relation to Medicine

By C. W. Carter, Dr. R. V. Coxon, D. S. Parsons and Prof. R. H. S. Thompson. Third edition. Pp. xiii+628. (London and New York: Longmans, Green and Co., Ltd., 1959.) 50*s*. net.

THE last edition of this well-known text-book was published seven years ago, and this new edition shows many changes. To begin with, the number of authors has increased from two to four, and the character of the book has been somewhat altered by the omission of the practical sections. The authors feel that universities and medical schools prefer to plan their practical classes in their own way. The original chapters have been extensively revised to bring them up to date, and there are some excellent new chapters dealing with the digestive secretions and intestinal absorption. In the light of increasing knowledge, much more stress is put upon the nature and mode of action of the endocrine secretions, and problems of electrolyte balance and renal function have been given more prominence. All this has led inevitably to a considerable increase in the size of the book, but to offset this it can be said that a good deal of the new material covers topics which, hitherto, have usually been regarded as falling more within the province of physiology. To biochemists, used to seeing so much of their subject included under the heading of physiology in the text-books, it is gratifying to find that, with advancing knowledge of hormone action and so on, the tables are now being turned.

This book is written primarily for students reading for a degree in biochemistry or physiology as well as for medical students, but needs of postgraduate workers have also been kept in mind. It follows that the book contains far more detail than most 2nd M.B. students can be expected to cover in the limited time they have for biochemistry. Moreover, for them, the bibliography of more than fifty pages is quite unrealistic—a few selected references to reviews would be much less daunting. It was disappointing not to find any mention of the development of British anti-lewisite. Perhaps this was modesty on the part of one of the authors (R. H. S. T.), who was associated with this fine piece of war-time research of the Oxford School of Biochemistry; but the work is still of great interest, and it affords an excellent example of fundamental biochemical research which has led to valuable practical advances in medical treatment. Perhaps it might be included in future editions.

D. C. Harrison

CARDIAC NECROSES

The Chemical Prevention of Cardiac Necroses

By Prof. Hans Selye. Pp. x+235. (New York: The Ronald Press Company, 1958.) 7.50 dollars.

This extraordinary monograph reports work done by an anonymous team of investigators (acknowledgments are confined to secretarial staff) following the discovery in 1957 that a cardiomyopathy with necroses could be induced in rats by the administration of cortico-steroids and certain electrolytes; this condition was called "electrolyte-steroid-cardiopathy with necroses", but abbreviated to E.S.C.N.

It had been known for some 14 years beforehand that steroids administered with sodium chloride could induce a hyalinizing myocarditis (without necrosis) associated with periarteritis nodosa and nephrosclerosis. The new discovery excited interest because of the prominence of myocardial necrosis and the lack of the associated lesions just mentioned. The nature of this new lesion suggested to Prof. Selye a possible relationship with myocardial necrosis induced by other means, such as potassium deficiency, administration of digitalis or vitamin D sterols, in experimental animals and occurring for reasons unknown in man.

The experiments reported here show that steroids with both gluco- and mineralo-corticoid activity are necessary for the production of this condition. Sodium chloride has no effect on its development, unless the animals are also subjected to 'stress', but sodium phosphate, sulphate, or perchlorate will induce it in the animal previously treated with steroids. Other electrolytes, it appears, have a protective quality when administered simultaneously; the most potent of these are potassium and magnesium chloride.

The bulk of the book is devoted to reporting these experiments giving the detailed results of the innumerable permutations of steroids, electrolytes, both aggravating and protective, and various unpleasant sounding forms of 'stress' applied to series of rats. The rest of the book is given to an introductory review of the historical background and to discussion of the possible hypotheses applicable to the observed results. There is finally a prophetic chapter discussing the future significance of these results in relation to the possible use of simple electrolytes to prevent myocardial necrosis in man.

The experimental study was certainly ambitious and thorough, but in some respects seems to have been over-elaborated. Prof. Selye sees great relevance in his observations on rats to certain naturally occurring conditions in man, but it is difficult to accept this. The discussion which deals with this aspect of the work and which, perhaps not surprisingly, rejects other hypotheses in favour of regarding the necrotizing cardiopathies "As 'Diseases of Adaptation' caused by some derailment of the General Adaptation Syndrome" lacks conviction and is often specious.

The following passage seems characteristic of the book: "Since the discovery of the E.S.C.N. less than a year ago, more than 30,000 rats were used in this Institute for experiments designed to clarify certain aspects of this subject. It is evident that the complete evaluation of this enormous mass of material poses almost insuperable problems and many of our present hypotheses will undoubtedly have to be abandoned in the light of future research". One wonders if the death of the 30,000 was worth while.

WATER RESOURCES

Ground Water Hydrology

By Prof. David Keith Todd. Pp. xii+336. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 86s. net.

The increased demand for water in recent years, in the form of major water supply and irrigation schemes in all parts of the world, has accentuated the importance of the assessment and development of ground-water resources. This trend is by no means confined to under-developed countries. In England and Wales, for example, the estimated demand for water in 1965 is one and a quarter times that of 1955. In this sense, Prof. Todd's book is timely. Too long has ground-water been considered in a woolly, qualitative fashion by engineer and geologist. The need is for a quantitative assessment of ground-water resources and development potential. The recent application of the radioactive decay of tritium to the time dating of water is undoubtedly the key to quantitative work and marks the beginning of what may be a fruitful period of study.

This readable and well-presented text is addressed to a wide group—"students, specialists in hydraulics, geologists . . ." and is a comprehensive account of fundamentals, methods and problems in the field of ground-water hydrology. The reader is led very logically through the geology of occurrence of ground-water to the equations of seepage and flow into wells. While the subject-matter is familiar, the presentation is fresh and clear. It is inevitable that pure American practice is presented at times, as in the chapters on the construction of wells and the legal aspects of ground-water, but this is more than balanced by the American contributions in the form of "Basin Wide" development and artificial re-charge, for which work Prof. Todd is best known in Europe. Both these topics are new to text-books and they make a significant contribution to the value of the book.

The extent to which ground-water technology is indebted to the petroleum industry is shown by the two chapters on surface and sub-surface investigation techniques. Highly developed resistivity, seismic and magnetic methods are benefits derived from this wealthy relation.

The text is supported by well-chosen American data and an impressive array of some seven hundred references.

E. Miller

Thyroid Radioiodine Uptake Measurement

A Standard System for Universal Intercalibration. By Dr. Marshall Brucer. Pp. ix+323. United States Atomic Energy Commission. (Washington, D.C.: Office of Technical Services, Department of Commerce, 1959.) 3.50 dollars.

THE measurement *in vivo* of the radioactive iodine content of the human thyroid is a deceptively simple procedure. Determinations of this type have been made with increasing frequency during the past twenty years, and are now widely used in the course of clinical diagnosis and radioisotope therapy, as well as in numerous investigations of thyroid function. It has long been known, however, that the calibration involved in such measurements depended critically upon the spectral sensitivity and shielding of the counting equipment used, as well as upon its geometrical relationship to the thyroid and the effects of scattering and absorption of radiation in the neck tissues.

In the course of discussions at Oak Ridge in 1953, and of subsequent inter-calibration measurements, it became clear that many laboratories and hospital departments were relying on inappropriate and quite inadequate techniques of calibration, and that gross systematic errors were being made in the estimation of the radioiodine content of the gland and therefore in the percentage uptake of any dose, since the *in vitro* measurements of the dose were not subject to corresponding discrepancies. The present publication by Dr. Marshall Brucer describes at length the effects upon the observed counting-rate of the counter shielding and collimation, the counter type and spectral sensitivity, the thyroid position, the scattering and absorption of radiation by body tissues, and the body content of radioiodine at the time of the measurement.

The book gives the text of a series of lectures on uptake measurements, and preserves their bulk and narrative character, with numerous explanatory diagrams and a non-mathematical form, and without any attempt to achieve a compact or formal analysis which would in any case be awkward in so practical and applied a problem. The material discussed will be of considerable value to those concerned with similar *in vivo* measurements and whose methods have not been subjected to detailed examination of this type.

E. E. POCHIN

The Metabolism of Sulphur Compounds

By Leslie Young and George A. Maw. Pp. 180. (London: Methuen and Co., Ltd., 1958.) 16*s*.

THIS small book, one of the Methuen "Monographs on Biochemical Subjects", succeeds admirably in its object of giving a general survey of the metabolism of sulphur-containing substances. It directs attention to the great diversity of sulphur compounds in Nature, but deals, from the metabolic aspect, with many substances which have not been found in living organisms in addition to those of natural occurrence. The reader cannot fail to note the uncertainties which still exist regarding the precise course of the most important metabolic processes, such as the desulphuration of cysteine, the oxidation of this substance to sulphate, its conversion to taurine and finally its synthesis in micro-organisms. The formation of thiosulphate is also imperfectly understood. It is perhaps significant of the way in which the study of sulphur metabolism has developed that the authors have virtually restricted themselves to higher animals and micro-organisms and that the latter are dealt with in a single chapter. Although the authors state that plants and micro-organisms are responsible for the greater part of the interconversion of sulphur compounds in Nature, practically nothing is said of sulphur metabolism in plants; several unusual compounds which occur in plants are nevertheless mentioned. The authors, experts on their subject, have covered, however, the metabolism of sulphur compounds in higher animals in the widest possible manner, and are to be congratulated on producing a critical, well-written, informative and thoroughly documented introductory text-book.

G. D. GREVILLE

Health in Industry

By Donald Hunter. (Pelican Book A441.) Pp. 288+18 plates. (Harmondsworth, Middx.: Penguin Books, Ltd., 1959.) 4*s*.

THE history of occupational disease spreads over many years and, until comparatively recently, ailments like beat knee, 'stagmus', writer's cramp, grocer's itch and cotton-workers' throat were accepted as heavenly or other visitations about which little could be done. With the growth of the industrial revolution the number of diseases multiplied so much in factory, workshop and mine that few industrial workers were able to get through a life-time free from occupational disease.

Since the industrial revolution began in Britain, it was fitting that British doctors should first assume responsibility for the health of the workers. This interesting book by a senior physician to the London Hospital, and one who has had long experience in industrial medicine, describes the genesis of industrial medical services and the way they have developed. Rightly, the author emphasizes that in this field prevention is better than cure, and that responsibility for prevention rests not only upon doctors but also upon the Government, architects, management, trade unions and the workers they represent.

T. H. HAWKINS

Fertilizers and Profitable Farming

By Dr. G. W. Cooke. Pp. xviii+122. (London: Crosby Lockwood and Son, Ltd., 1959.) 15*s*. net.

IN this small book Dr. G. W. Cooke, head of the Department of Chemistry at the Rothamsted Experimental Station, has presented the substance of a series of lectures given to farmers. It is a straightforward account of how commercial fertilizers can be used to the greatest economic advantage. This has now become a matter of major concern to most arable farmers, and, though much of it is a matter of common sense rather than applied science, experimental results obtained in research fields and laboratories have supplied valuable quantitative data on which generalized recommendations about amounts, composition and application of fertilizers to different crops can be based. Dr. Cooke has used such data to make recommendations for fertilizing the principal British arable crops and grassland, and points out what adjustments are required for different conditions of soil and climate. The book is packed with useful information, but is too short to cover adequately operations on which British farmers spend £90 million a year. It deserves a better index than it has been given.

G. V. JACKS

THE INLAND FISHERY RESEARCH STATION, SAGANA, KENYA

By Dr. VERNON D. van SOMEREN, M.B.E.
Ministry of Forest Development, Game and Fisheries, Kenya

IN the period of reconstruction immediately following the Second World War, it was realized that future fisheries development in the Colonies must be based on scientific research, and to this end various developmental grants were made both by Her Majesty's Government in Great Britain, and by Territorial Governments, to enable fishery research stations to be established in various parts of the world.

In East Africa, such grants were the origin of two interterritorial fishery research stations under the ægis of the East Africa High Commission ; one dealing with marine fisheries off the East African seaboard and based in Zanzibar (East African Marine Fisheries Research Organization), the other dealing with freshwater fisheries mainly in the great lakes of East Africa, and based in Jinja, Uganda (East African Fisheries Research Organization).

On a territorial basis, grants from the Kenya Government enabled the establishment of two small freshwater research stations in Kenya Colony. One of these, the River Research and Development Centre, was situated on the slopes of Mt. Kenya about twenty miles from Nyeri at an altitude of about 6,000 ft., and has already been described[1]. After six years work, mainly on trout fisheries[2], this station had to be evacuated in 1953 as a result of the Mau Mau disturbances ; it was re-opened again in 1956 as a trout rearing station only.

The other research station was started as a small fish culture farm, based at Sagana, some sixty miles north of Nairobi, at an altitude of less than 4,000 ft. Before any large-scale development could take place here, it also was evacuated as a result of Mau Mau activity. It was, however, possible to re-open it again in late 1955, and it has since been expanded and developed as the Inland Fishery Research Station of this Ministry. Funds were made available both from Kenya development grants, and more recently, in 1959, under the Colonial Development and Welfare Acts of the United Kingdom.

The Station now occupies an area of some 180 acres, ideally situated on the main Nairobi–Nanyuki road, adjacent to Sagana railway station, and is at present developed to the extent of 18 one-acre ponds, 7 half-acre ponds, 8 quarter-acre ponds, 3 four-acre dams, 1 two-acre dam and numerous small breeding and experimental ponds, all well served by interconnecting roads.

The principal buildings include some housing, offices, stores and a main laboratory consisting of three rooms, a library room, stores and aquarium room. This latter has incorporated in it a long running-water channel, fed by the main pond supply furrow, and fitted with an underwater observation chamber ; in this the observation of river fish can be carried out, and spawning behaviour studied on various types of artificial bottom. There are five large static aquaria, and numerous smaller tanks.

The ponds themselves are supplied by a gravity furrow taken from the Ragati River, which runs through the grounds of the Station, and is affluent on one boundary to the very much larger Tana River which drains eastern Kenya. Within two miles of the Station, there are large hydro-electric installations on the Tana, and others are being considered, which will be of considerable fishery interest.

Both the Tana and the Ragati in the vicinity of the Station have falls of up to 15 ft. in their course, and above and below these falls there is in both rivers a good selection of indigenous fish such as cyprinids, eels, siluroids, cichlids and mormyrids. In order to study the biology of these indigenous river fish, the Ragati, a few hundred yards from the laboratory, has been spanned by a concrete weir supporting a horizontal grid trap of novel design, which traps all fish running both up and down (Fig. 1).

Last year, with only intermittent operation for nine months, the downstream grid of this trap yielded a catch of 366 lb. of fish, of which 264 lb. were eels, of two Indian Ocean species ; and at this trap an intensive marking programme of migratory fish is in progress, which is already yielding much valuable information on movements in relation to water conditions, spawning biology and growth. The biology of all these river fish is very imperfectly known. A small elver trap of traditional pattern has been erected at the Ragati Falls, and has already given results of interest[15].

River-water temperature and height are recorded continuously by instrumentation ; velocity, turbidity, and conductivity once daily. On the adjacent Tana River, there are a number of small indigenous basket trap fisheries, which have already been studied[3] ; the twice-yearly flood régime of the two rivers is a subject of particular study, since the large indigenous fisheries farther downstream are entirely dependent on these, and the commercial potential of the Tana, in particular, is large.

The climatic conditions at Sagana on the Station are recorded twice daily from Stevenson screen measurements, sunshine recorder, anemometer, and evaporation pan data.

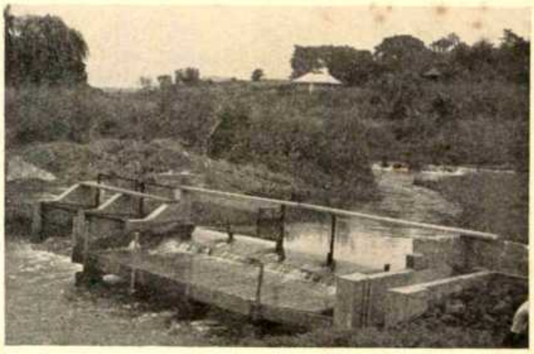

Fig. 1. Two-way fish trap on Ragati River. Upstream traps on left, horizontal grid downstream trap on right

The major part of the pond area is devoted to experimental cultural work, mainly on *Tilapia nigra*, an indigenous river cichlid ; this species has proved particularly suitable for the monosex technique of culture developed formerly at this Station[4]. Easier, and more rapid, applications of this method have already been developed[5], since it has been shown that growth potential even after maturation is very marked ; males can now be separated for fattening on the basis of breeding coloration only, and growth is very rapid even though they may already have bred.

Such sex-separation techniques, in addition to being an economic possibility, also offer a means of very precise population control in a pond, and hence are a most useful research tool in elucidating the factors which control basic growth, and hence final yield. Thus, monosex populations have already been used to determine the effect of depth and turbidity of water[6], sexual dimorphism in rate of growth[7], seasonal growth patterns[8], and effects of alterations of stocking density[9].

At the same time, attention is also being paid to different methods of cropping mixed breeding populations[10]. The value of all such experiments has been enhanced by tagging techniques[11] for recognition of individual and batches of fish, and the effect of such tagging determined[12].

At present, experiments are in progress on *Lebensraum* effects, further cropping methods, and a study of the scale structure changes found to be induced by monosex cultural procedures. Some twenty miles from Sagana, there is a large rice irrigation project, on which fish culture experiments are also in progress in co-operation with the Ministry of Agriculture, these being fertilization trials. To date, it would seem that ordinary farmyard manure and sulphate radicals (with or without nitrogen) increase final yields, though phosphates may have a depressing effect. No fertilization experiments are in progress at Sagana itself until the basic growth features of the ponds there have been finally determined, since any additives may change once and for all the basic composition of the pond.

Part of the Station is given over to the rearing and free distribution of fingerlings for elsewhere in the Colony. Other species under study are *T. mossambica*, *T. zillii*, a *Tilapia* from Zanzibar, and the new hybrid *T. zillii* × *T. nigra*, recently described[13].

Morphological, systematic and biological studies are also being made, such as that on the feeding mechanism of *T. nigra*[14]. River prawns, *Macrobrachium* spp., have recently become the subject of cultural study, since they could form a high-priced cash crop, but in general *T. nigra* still remains the main object of study, since in any such station confusion and mixing of fish can all too readily occur ; the strictest precautions are taken over this, as also over the control of predators such as birds.

The Station is staffed by one resident research officer, one fishery officer, two African laboratory assistants and ancillary staff. There is a great need for more intensive hydrological, chemical and botanical work in the rivers and ponds, which cannot be undertaken with present staff limitations, though the laboratory is now well equipped for additional techniques.

The Station works in the closest co-operation with the interterritorial organization at Jinja, with which mutual interchanges of staff have been of great value, and the work is complementary, but in no way overlapping. The Nuffield Trust has recently awarded a two-year grant to support a research worker for certain observations on *Tilapia* biology to be carried out at both stations, but to date of writing (March 1960) no suitable candidate has yet been forthcoming.

Limited guest house facilities and working space are available at Sagana for visiting workers, though it is not possible to assist any such visits financially. With both river and pond facilities available, however, Sagana offers research opportunities almost unique in the overseas territories, in climatic conditions which are by no means unpleasant.

A SYNOPTIC STUDY OF INFRA-RED RADIATION OVER THE UNITED STATES

By Dr. JOHN L. GERGEN and Dr. WILLIAM F. HUCH

School of Physics, University of Minnesota

DURING the nights of May 26–30, 1959, twenty-five United States Weather Bureau stations co-operated in a synoptic study of infra-red radiation conditions across the United States. These twenty-five stations, each of which has the newer *AN/GMD*-1 radiosonde telemetry equipment, sent aloft Black Ball flights instead of the regularly scheduled wind soundings at 0600 G.M.T. The Black Ball[1] is an instrument which measures, at any height, the total radiation incident on a roughly spherical surface ; the quantity actually observed is the temperature, T_B, of a convection-shielded black absorber. This temperature is corrected for the effects of the thermal time constant and the residual convection to obtain the radiation temperature, T_r, which is a measure of the total radiation reaching the instrument.

The experiment was planned to take place on the nights of May 26, 27 and 28, 1959, and the radiation instruments and modified radiosondes were distributed to the participating stations before these dates. Some difficulty was encountered with faulty battery supplies for the radiosondes, however, and not all stations were able to launch flights on these scheduled dates. Each of the twenty-five participating stations reported results from at least one successful flight, however, and the experiment must be considered a complete success. The results include those for which a satellite experiment was previously proposed.

There are numerous ways of synthesizing the results obtained. Since the Black Ball measures the radiation temperature, T_r, at any level in the atmosphere, it measures at very high levels a temperature which is related to the total outgoing energy from the Earth and the atmosphere below. This is so because at sufficiently high levels the infra-red radiation propagated downward is completely negligible, due to the extreme tenuousness of the atmosphere still overhead. At a sufficiently high level, if the outgoing power per unit area, dP/dA, is expressed as a function of an equivalent temperature of upward propagated radiation, $T\uparrow$, then the radiation temperature at this level is given by :

$$dP/dA = \sigma T\uparrow^4 = 2\sigma T_r^4 \qquad (1)$$

so the power-loss per unit area by the Earth to space can be readily determined from the observed high-level radiation temperatures.

In practice, at temperate latitudes, the radiation temperature is observed to remain constant with increasing altitude above about 100 mb., or 15 km. From the results obtained at the stations the flights of which reached high altitudes it is possible to draw isopleths of constant power per unit area lost to space by the Earth and the atmosphere below, as a function of geography. Plots of this kind for the three nights of the experiment are shown in Figs. 1, 2 and 3. The power-loss to space varies from 15·6 to 26·6 MW /cm.² over regions which are small compared to the extent of the United States.

Several conclusions are immediately apparent from the observed results :

(1) Clouds have an overwhelming effect on the propagation of infra-red radiation through the atmosphere. The observed power-loss to space is not obviously dependent on the total atmospheric moisture or on the latitude, only weakly dependent on weather systems, and strongly dependent on cloud cover.

(2) The variation in power-loss to space over a relatively small geographical region on any one night is at least as large as the variation in the mean power-loss to space from equator to poles ; the same is true for any one location, comparing conditions from one night to the next.

(3) Since infra-red radiation is the only mechanism by which the Earth can lose to space the energy it gains from the solar illumination, the observed power-loss to space, which varies by a factor of 2 over

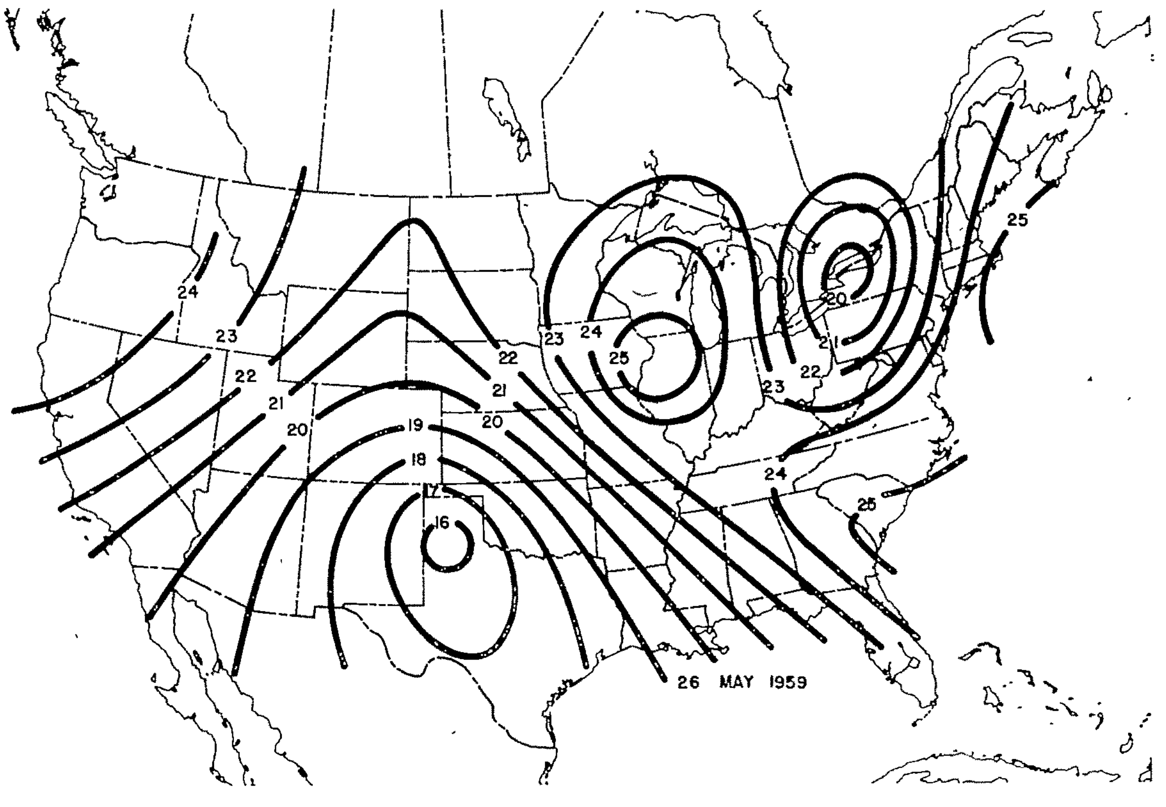

Fig. 1. Isopleths of constant power-loss to space per unit area (MW./cm.²) observed over the United States on May 26, 1959

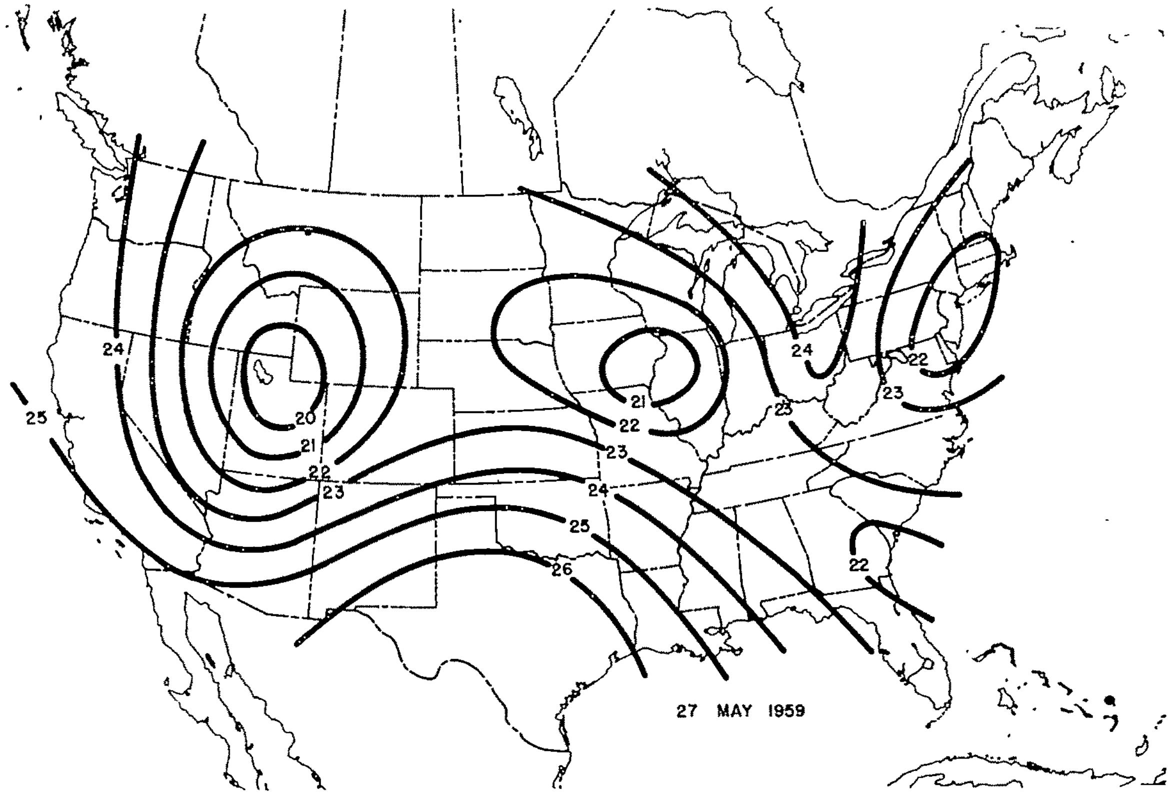

Fig. 2. Isopleths of constant power-loss to space per unit area (MW./cm.²) observed over the United States on May 27, 1959

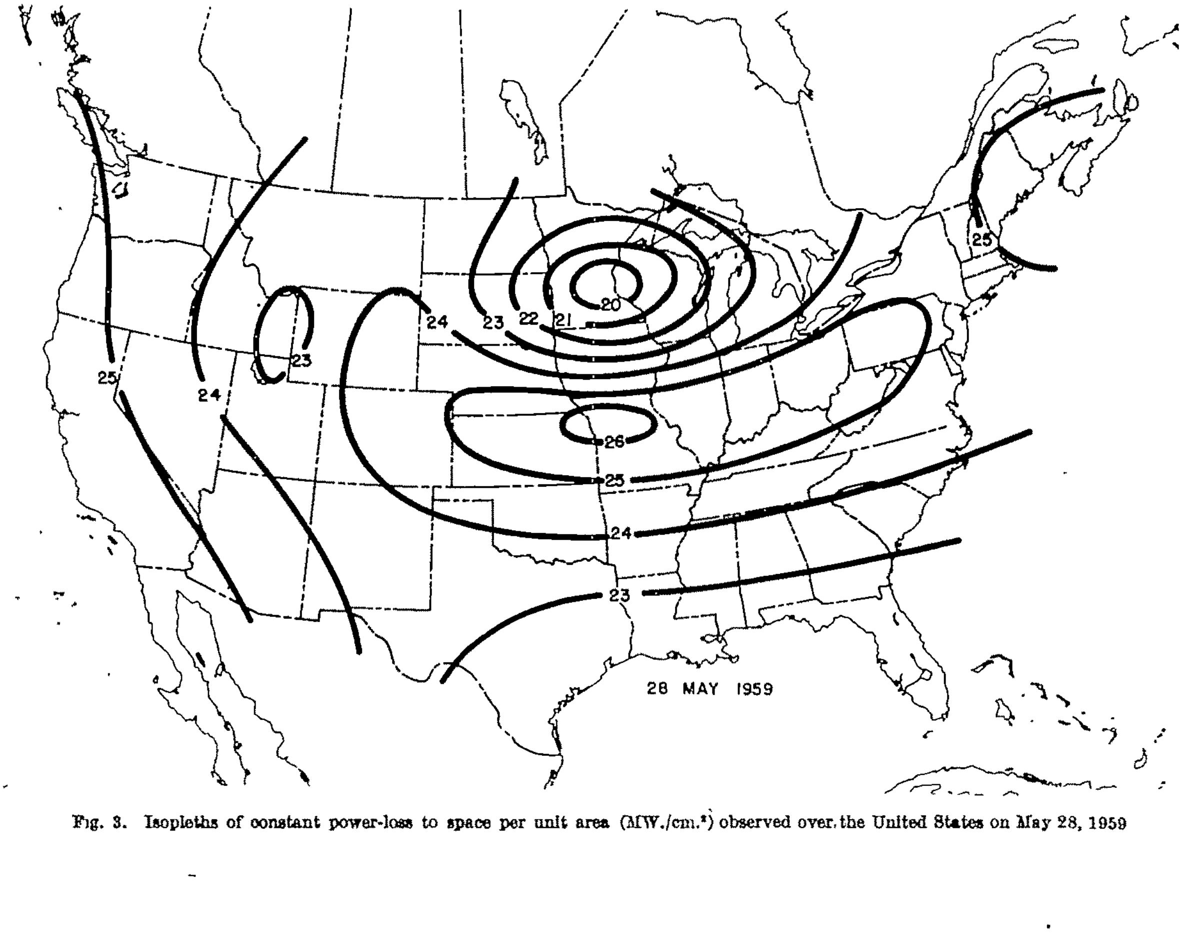

Fig. 3. Isopleths of constant power-loss to space per unit area (MW./cm.²) observed over the United States on May 28, 1959

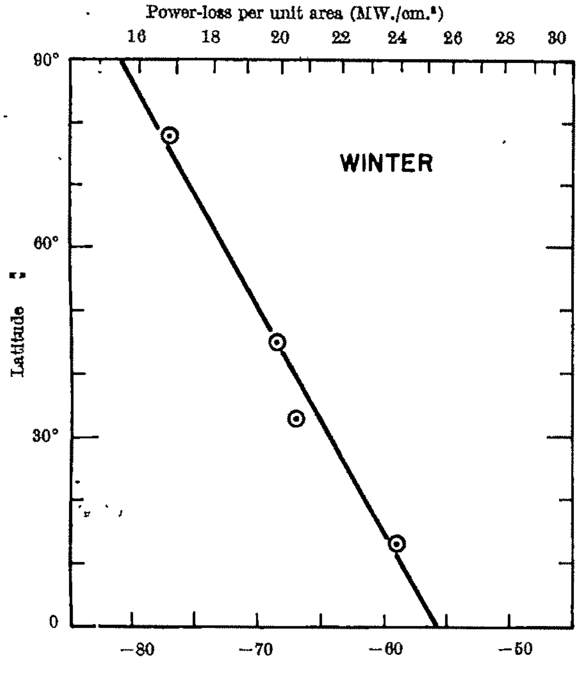

Fig. 4. Observed mean power-loss to space per unit area (MW./cm.^{2}) as a function of latitude, given in terms of an equivalent radiation temperature. Each point is an average of at least eight individual soundings which reached high altitude

very small distances, must significantly affect the formation and propagation of weather systems.

The radiation 'lows' which are observed are found to be due mainly (perhaps exclusively) to clouds existing at high levels, 300–150 mb. These clouds, in some cases, are associated with the weakest cloud patterns observed by the standard synoptic network; in most cases, it is impossible even to track the movement of these cloud patterns from the surface reports.

During the three days covering the experiment, a weak front and trough separated the drier air over the south-western United States from that in the eastern part of the country. The difference in total atmospheric moisture does not appear to affect the observed radiation pattern at all significantly.

The mean winter-time power-loss to space, expressed in terms of the observed high-level radiation temperatures, is shown as a function of latitude in Fig. 4. The points shown are from results obtained at Taguac, Guam (13° N.), Holloman Air Force Base, New Mexico (33° N.), and Minneapolis, Minnesota (45° N.), in January, and McMurdo Sound, Antarctica (77° S.), in July. Each point represents an average of at least eight soundings. This number has been found to give a good average because of the large fluctuations of the high-level radiation temperature from day to day at any one location. The mean power-loss to space from these results varies from 15·6 to 25·2 MW./cm.^{2} in going from the equator to a pole, a smaller variation than is observed on any one night across the United States. If one grants that the net radiation unbalance over latitude is responsible for the generation of weather systems and air motions, it must follow that the large radiation differences shown in Figs. 1, 2 and 3, occurring over small geographical regions, play an important part in controlling and modifying the weather systems existing there.

One further conclusion might immediately be drawn from the observations: the very nominal cost of flying the Black Ball as a standard synoptic instrument would be repaid many times over in detailed fundamental knowledge of the Earth's heat balance.

---

NEW CLATHRATE COMPOUNDS OF THE INERT GASES

By J. G. WALLER

British Oxygen Research and Development, Ltd., London, S.W.19

A NUMBER of authors have claimed to have produced compounds of the inert gases. Thus, Crooke in 1906 postulated a reaction between molten zinc and helium gas[1]. Between 1927 and 1940 Damianovich published a large number of papers relating to compounds between inert gases and metals[2]. He claimed these compounds were formed when a glow discharge was struck between metal electrodes in an atmosphere of the inert gas at low pressure. Solid deposits were said to form around the electrodes, and these deposits were claimed to be compounds between the gas and the metal of the electrode. Boomer also claims to have formed a "tungsten helide" in the same way[3].

These processes for producing stable compounds of the inert gases have been re-examined. Discharges were passed between platinum or tungsten electrodes at about 5,000 V. in helium or argon, but no solid deposits containing appreciable amounts of the gases were obtained, although considerable sputtering of the metal of the electrodes occurred and some occlusion of gas could have taken place. Some experiments were conducted in which one electrode was a platinum gauze, with a third electrode just behind it. This third electrode was a coil of tungsten wire that could be heated. It was thought that inert-gas ions might be accelerated towards the gauze electrode, pass through it and form a compound on impact with the tungsten, either when hot or when cold. Again, no compounds were observed.

Other compounds have been claimed to exist between argon and boron trifluoride[4]. The evidence for their existence came from small differences in the freezing point of argon–boron trifluoride mixtures of different compositions. These differences in freezing point were small and were probably due to experimental errors. Later, other workers were unable to find any evidence for compound formation, under identical conditions, between boron trifluoride and argon, krypton or xenon, or between xenon and trimethylboron, sulphur dioxide, hydrogen sulphide, ether or methanol[5].

Various other chemical compounds have been claimed from time to time but none has been substantiated, and it may be concluded that the inert gases are truly inert. However, one class of compounds of the inert gases does exist, although they can scarcely be called chemical compounds since the electrons of the inert gas atoms are not involved in the binding forces which are responsible for their existence. These are the clathrate compounds.

The name 'clathrate' was coined by Powell to describe the compounds between quinol and inert gases in which the inert gas atoms fill cavities in the crystal lattice of the quinol[6]. They are therefore a solution of gas in the solid matrix. A review of much of the work on clathrate compounds has recently been published[7]. Such compounds are formed by argon, krypton and xenon as well as by other gases, when quinol is crystallized very slowly from a suitable solvent under an atmosphere of the gas at an elevated pressure. Stable solids are obtained that, on warming, evolve the gas. Recently, use has been made of these compounds as a means of handling a radioactive isotope of krypton (krypton-85)[8].

The hydrates of argon, krypton and xenon were prepared soon after the gases themselves had been isolated. The original work was published by Villard in 1896[9] and later confirmed by de Forcrand[10]. These workers showed that the inert gas hydrates conformed with hydrates of other gases in having a formula $X.5{\cdot}75H_2O$. More recent work by von Stackelberg has shown that the gas hydrates are, in fact, clathrate compounds[11–16]. Hydrates of krypton and xenon with heavy water have been prepared[17].

While the simple hydrates of the inert gases are known, little has been published on their double hydrates. This article describes some of these compounds.

Hydrates were made under elevated pressure in a stainless steel vessel or at atmospheric pressure in glass.

The high-pressure vessel was provided with a tube through which gas can be admitted under pressure and a side valve in the head of the vessel. By allowing gas to escape slowly from the side valve and maintaining the pressure in the vessel, gas was bubbled through the liquid in the vessel, thereby causing some agitation.

Argon at pressures up to 120 atm. was taken directly from a cylinder supply. For higher pressures it was fed into a 4,000 atm. compressor of the mercury piston type manufactured by Hart. Krypton and xenon were used at pressures up to 10 atm. from a cylinder supply and for higher pressures they were compressed in the Hart compressor.

Double hydrates were prepared using acetone, methylene dichloride, chloroform or carbon tetrachloride as the third component. After it had been shown that the compounds obtained were of the type described by von Stackelberg[13], having a formula $A.2B.17H_2O$ where A is the organic component and B the inert gas atom, liquid mixtures were used having the composition of 1 mole solvent to 17 moles water. Preparation of the acetone compounds was carried out by cooling in a bath at about − 30° C., while the other compounds were prepared in a cooling bath at between −5° and −10° C. To maintain a fine suspension of the halogenated methanes, about 0·01 per cent of sodium dodecylbenzene sulphonate was added to the water. The argon compounds were prepared at pressures between 200 and 400 atm., the krypton compounds at about 30 atm. and the xenon compounds at atmospheric pressure.

Table 1. TEMPERATURE AT WHICH DECOMPOSITION PRESSURE IS ONE ATMOSPHERE (° C.)

Inert gas	Organic liquid			
	Acetone	Methylene dichloride	Chloroform	Carbon tetrachloride
Argon	− 8·0	− 7·0	− 4·8	− 1·6
Krypton	− 5·0	+ 6·2	+ 9·0	+ 11·3
Xenon	+ 3·0	+ 8·6	+ 10·9	+ 13·7

The relative stabilities of the hydrates were determined by measuring the temperatures at which their dissociation pressures were one atmosphere (Table 1).

It will be seen from Table 1 that the stability increases from argon to krypton to xenon and for the third component in the sequence acetone (least stable), methylene dichloride, chloroform, carbon tetrachloride (most stable).

The xenon compounds were sufficiently stable to be formed simply by bubbling the gas through the appropriate solvent mixture cooled to 0° C. All the krypton compounds, except the acetone compound, could be obtained in the same way. However, the amount of gas taken up by the hydrates formed at atmospheric pressure was low and was usually less than 20 per cent of the theoretical amount. At higher pressures the gas content rose to about 100 per cent of the theoretical value.

In addition to the inert gas compounds, double hydrates of oxygen and of nitrogen with acetone and of nitrogen with carbon tetrachloride were prepared, but no reliable data on these compounds were obtained.

A number of other organic liquids were examined. Of these, *n*-butyl alcohol, methyl ethyl ketone, dimethylamine and ethylamine appeared to give double hydrates, none of them as stable even as the acetone compounds. Methyl, ethyl and propyl alcohols, glycol, glycerol, formaldehyde, acetic acid, ammonia, methylamine, hydrazine, hydroxylamine hydrochloride and chloral hydrate gave no evidence of double hydrate formation.

Attempts to make hydrates with benzene were also unsuccessful. This was a little surprising, since, according to the data given by von Stackelberg, the benzene molecule appears to fit the large cavities in the double hydrate lattice exactly[12]. Von Stackelberg mentions a double hydrate of benzene and hydrogen sulphide.

The crystallographic structure of some of the inert gas compounds was examined. The results showed the presence of a complex cubic hydrate, in agreement with the formula proposed by von Stackelberg, that is, one molecule of organic compound, two inert gas atoms and seventeen water molecules. The best pattern was obtained for the argon–acetone compound, which gave a cell dimension, a = 17·34 Å. This value is close to those for hydrates of type II reported by von Stackelberg[12]. All the other compounds showed patterns for both ice and hydrate in varying proportions. Generally, the cell dimensions were in the range 17·3–17·5 Å.

The double hydrates of the inert gases have not been reported before. Most of the work on double hydrates has been concerned with hydrogen sulphide as the gas. Carbon tetrachloride, chloroform and methylene dichloride have been used by earlier workers as double hydrate formers, but acetone has not been reported.

Von Stackelberg suggested criteria for the properties of organic compounds that are capable of hydrate formation[11]. In particular, they should not have strong van der Waals forces and, consequently, their boiling points should be less than 60° C.; furthermore, they should not exhibit strong hydrogen bonding and therefore should generally be insoluble in water. Acetone, of course, has a fairly low boiling point (56° C.) but it is soluble in water. Recently, von Stackelberg has described hydrates of water-soluble ethers, such as dimethyl ether and ethylene oxide[18]. He ascribed the solubility of these ethers in water to effects not associated with hydrogen bonding and therefore suggests that they fit in with his criteria for hydrate-forming molecules. However, Gordy's work on hydrogen bonding indicated that the ethers do exhibit some hydrogen bonding[19-21]. The proton-attracting power of acetone is, according to Gordy, about the same as that of dioxane, a cyclic ether, and less than that for diethyl ether. All show smaller proton-attracting power than the alcohols. It therefore seems that acetone can be classed with the ethers as an organic molecule that does not produce strong hydrogen bonds with water.

In conclusion, it may be said that a new series of double hydrates of the inert gases with acetone has been prepared. These compounds are of the same form as the double hydrates of chloroform or carbon tetrachloride with hydrogen sulphide. The inert gases also form double hydrates with carbon tetrachloride, chloroform and methylene dichloride.

I wish to acknowledge the assistance of Mr. D. Clark of the Royal Aircraft Establishment, Farnborough, Hants, in carrying out the crystallographic identification of the double hydrates.

Thanks are due to the directors of British Oxygen Research and Development, Ltd., for permission to publish this work.

INTRASPECIFIC DIFFERENTIATION: BIOLOGICAL AND SOCIAL ASPECTS

By Dr. MAX PETTERSSON

Brunel College of Technology, London, W.3

SIR JAMES GRAY has recently reminded us that it is quite 'proper' to seek rational pathways through palæontology to archæology and history; through sociological as well as biological evolution[1]; and it seems useful, in this connexion, to review the progressive differentiation among individuals of the same species.

Thus (1) slight ontogenetic differentiation will have occurred very early, between older and younger individuals. (2) Recombination, etc., gives genotypic differentiation among individuals of the same age. (3) Incipient speciation is also intraspecific; but not, of course, the follow-through of full speciation and adaptive radiation. (4) The individual of the diploid phase became different from that of the haploid; and it is fascinating that in several independent cases it was usually the diploid which then forged ahead, presumably due to the greater variability of its larger gene complement. (Within the multicellular individual, the differentiation among cells is well known; and most motile animals of more than 1 mm.[2]—or more than one million cells—are now internally administered by a nervous system including some kind of 'brain'.) (5) Perhaps several times independently, anisogamy and oogamy arose, being a differentiation in function and structure among 'individuals' of the haploid phase.

Our own ancestors had already accumulated all the above forms of differentiation by 500 million years ago. Possibly by then, or not long after, they also became (6) diœcious, as opposed to hermaphrodite, with the haploid dimorphism thrusting back round the life-cycle to affect the diploid stage as well. (The 'incompatibility' of many modern plants is a kindred extension of No. 5.) (7) Either before or after diœcy, ontogenetic differentiation often becomes much pronounced: as in cestode, insect, amphibian and mammal.

The more successful among the larger land animals and plants of the past 100 million years—the mammals, birds and seed plants—have better developed 'care of young'. So have some Hymenoptera; and *Andrena*, *Osmia* and *Megachile*, for example, as well as *Halictus*, *Bombus* and *Apis*. One kind or other of this benign activity, on the part of the diploid parent, thrusts forward round the life-cycle to encompass both the haploid phase and the younger stages of the next diploid individual as well. With dioecy, this commonly involves (8) a pronounced part-time differentiation of function between adult female and male. While exceptions are known, it is predominantly the egg-bearing adult which develops these benign parental activities which seem to be at the root of all fully developed social life[1]. It is nowadays clear that young birds and mammals learn some of their behaviour after birth, as cultural tradition. Thus in mammals, in any event, it is not uncommon for (9) the mother to be further differentiated functionally as providing the rudiments of the young's informal education and moral training[2].

Within the past million years, our ancestors have experienced several further types of differentiation as among the individuals of the same species, though two of these types arose in the Hymenoptera long before. Perhaps long after the first toolmaking, man experienced for the first time (10) a full-time differentiation of function between adult males and females. In surviving societies in the food-gathering stage, there is commonly a pronounced differentiation of this kind. For example, the larger game animals are hunted by men only; and certain domestic skills are practised by women only. This occupational differentiation between men and women may have been standard custom throughout post-glacial times, and for long before. It also occurs in some hymenoptera[3]. Some of these have domesticated certain animals and plants for food. *Homo sapiens* did, too, much later; but the effect of this on the social life of man[4] has been more profound than on any hymenopteran.

Some wasps, bees and ants achieved societies large enough to evoke (11) full-time occupational differentiation between individuals of the same sex. Indeed such intrasexual differentiation occurs in societies of *Halictus malachurus*, where the number of adult females is as low as about a dozen, though total individuals are greater. But in man, such full-time intrasexual specialization is not attested until much larger societies developed. Man achieved communities large enough for this change only after the inception of domestication, of agriculture. Thus in the ancient 'cities', full-time priests, kings and scribes arose as administrators—compare nerve cells arising in multicellular organisms—while other full-time male specialists who became differentiated included smiths, potters and merchants. The original threshold value of settlement size, for this differentiation to become conspicuous, seems to have been about 10 hectares, or 10^5 square metres, as during the Fourth Millenium B.C. in Halafian Iraq and Amratian Egypt[5]. The population of such settlements was something like $10^{3.5}$. Much later, and apparently by independent and parallel social evolution, the same occupational differentiation among members of one sex took place in the New World too. It occurred in Peru in the First Millenium B.C., perhaps earlier than the Moche culture[6]. In man, there now soon arose (12) marked economic differentiation within one region. Thus in Third Millenium theocratic Egypt, the ratio of net equivalent income for sovereign and labourer was apparently sometimes about $10^5 : 1$; while it is only a little greater than $10^3 : 1$ in the United Kingdom to-day. Similarly, there arose (13) an intensified differentiation between richer and poorer regions. Compare Sumer and Greece in the Third Millenium B.C.; Greece and Britain in the First Millenium B.C.; and Britain and India since 1760 [7].

With our increasing mastery of the environment, in recent centuries, (14) the number of different specialist occupations has again increased tremendously. But especially since 1870, two further forms of differentiation among human individuals may be discerned. While the child is still mainly left to the benign attentions of its mother, and father, for several years after weaning, it is then given ten years formal education by parent-substitutes. This is a further thrusting forward of parent-like activity, round the life-cycle. It proceeds at least to the age of 15 (United Kingdom); indeed to beyond the time when the scholar has become a sexually mature individual. Thus (15) in England and Wales to-day, nearly 2 per cent of gainfully employed persons have become differentiated in this manner, having become dedicated to the profession of education. As a consequence of this development of education, a further kind of differentiation can become much more intensified, (16) a social differentiation based on real differences in ability; which could greatly intensify the existing occupational and economic differentiation.

Most biological differentiations in man (Nos 1, 2 and 4–8, above) are fixed or very firmly rooted. But when considering the development of society in the next few centuries, the sociological differentiations (Nos. 9–16), besides No. 3, are clearly to some extent capable of adjustment. The sociologist, after much more research, will need to consider which, among various attainable conditions, promotes greater social health besides mere survival. One cannot with certainty anticipate such findings. But it may be noted that in recent centuries some sociological de-differentiation[8] has in fact occurred. Thus (3), the incipient speciation of *H. sapiens*, due to reproductive isolation of populations in different regions, has been arrested and reversed; also (10) men and women are now very much less occupationally segregated; (11*a*) persons of different occupations now have much early education in common; indeed (11*b*) modern science itself was developed by persons who combined the abilities of craftsman and scribe; (12*a*) in many countries the institutions of slavery and feudal serfdom have disappeared, that is to say, the economic differentiation between 'free' and 'un-free' has lapsed; and (12*b*) the economic ratio between richest and poorest seems, in some advanced countries, now actually sometimes less than in ancient times.

Zoologically, man is often regarded as a relatively unspecialized animal—without horns, hooves or large canine teeth—and this is regarded as a factor contributing to his success. Some species of animal have become too specialized to survive environmental change, or to evolve further. Does the condition of less rigid or extreme differentiation among individuals in society correspond, in this respect, to being less specialized?

OBITUARIES

Sir David Pye, C.B., F.R.S.

The death of Sir David Pye, on February 22, at the age of seventy-three, at his home in Surrey, caused a deep sense of personal loss to his many friends and colleagues in university and government circles. He wore his eminence in science and engineering with a modesty and tolerance which engaged the warm affection of those who had the privilege of working with him. He was a scientist engineer who devoted much of his working life to the thermodynamics of the internal combustion engine and its design and construction. His wide knowledge and experience found their expression in "The Internal Combustion Engine", the standard English text-book and work of reference on the subject.

His heart was in university life. Educated at Tonbridge School and Trinity College, Cambridge, he began his career in 1909 as a lecturer in engineering at Oxford, and Fellow of New College, and ended it as Provost of University College, London, in 1951. He faced adverse circumstances and overcame formidable difficulties in both universities.

At Oxford, in the first decade of the century, engineering was fighting for its existence. Pye illuminated the scene in the course of his presidential address in 1952 to the Institution of Mechanical Engineers: ". . . There was one college where, for four years no student ever dared to risk the wrath of the Master, that was known to be impending for anyone who might be so rash as to suggest that he wished to take a degree in engineering science. Then, in 1913, we were astonished to receive a registration from the college in question. Vain jubilation! The wrath from heaven in the shape of the Master of the college, magnificent in full academic robes, was next morning at the doors of the engineering laboratory, demanding that his erring lamb should return to the classical fold. We never saw our potential student again".

One can almost see the quizzical look on Pye's face. He could not have been altogether surprised. Anger never came easily to him, but he must have resolved then and there to hang on. Throughout his life his invariable courtesy and reasonableness concealed a strong tenacity of purpose. Oxford engineers have good reason to be grateful to him.

The difficulties he faced at University College (the first institution in Great Britain to appoint a professor in engineering) were of an altogether different kind. He became Provost in 1943 of a bombed and dispersed College. It existed more in spirit than in fact, and when the War ended, the problem of satisfying the multitude of new and returning students called for a miracle. There was no miracle. There was only the diligent, steady, painstaking day-to-day effort of David Pye, tolerant as ever with those who wanted more than was humanly possible, and stimulating to those who were ready to share the real work. Before his period of office came to an end, the College had more than re-established itself as a great centre of learning and research. His anxieties were at times overwhelming, but his labours must, in the end, have given him a deep satisfaction.

Pye left Oxford in 1914 at the outbreak of war to become an experimental officer in the Royal Flying Corps. The then professor of engineering at Cambridge, Bertram Hopkinson, soon picked him out, and on demobilization in 1919 he went to Cambridge as Fellow of Trinity College and lecturer in engineering. There followed a most fruitful six years of teaching and research on volatile fuels pursued, largely during vacations, in collaboration with the late Sir Henry Tizard and Sir Harry Ricardo at his works at Shoreham.

His career in the Scientific Civil Service began in 1925 as deputy director of scientific research in the Air Ministry at the invitation of Mr. H. E. Wimperis, the first director. Wimperis and Pye laid the foundations of a vigorous and lively research department which was to prove its worth in the critical years ahead. The shadow of war was lengthening when Pye succeeded to the directorship in 1937, and again he faced a period of difficulty and anxiety. Air warfare and air defence loomed large in strategic importance, embracing many fields of science and engineering. New weapons, devices and equipment found their way into the Royal Air Force, and when Pye retired in 1943 he had carried the burden of the day, and what he set out to do was largely accomplished.

Pye disliked damping enthusiasms in others. His imagination gave him a real flair for uncovering other peoples' talents, and much of his life was spent in contriving circumstances favourable to their development. His interests and activities were wide, ranging from enthusiasm for mountaineering and rock climbing, to the love of music and musicians. Many young professionals and amateurs owe much to his warm encouragement.

He married in 1926 the daughter of C. Moore Kennedy, Virginia Frances, who nursed and comforted him throughout the long illness at the end of his life. Our sympathies go out to her, and to her two sons and daughter. BEN LOCKSPEISER

Prof. B. Gutenberg

With the death of Beno Gutenberg on January 25, seismology loses an outstanding figure. Throughout an academic career of nearly half a century he maintained an astonishingly large output of high-grade papers covering the whole range of seismology, especially in connexion with the propagation of seismic waves through the interior of the Earth. Indeed, it was truly remarked by Prof. Perry Byerly on the occasion of the presentation to Gutenberg of the Bowie Medal of the American Geophysical Union: "It is rare that anyone writes a paper in seismology without referring to him". Of his many achievements perhaps his most celebrated was the calculation in 1912 of the radius of the so-called liquid core of the Earth, usually referred to as the Oldham–Gutenberg core, the existence of which had been inferred by R. D. Oldham in 1906; considering the roughness of the existing data and the tentative methods then available this stands out as a veritable *tour de force*, and calculations by Jeffreys with a large body of precise data, embodying reflexions from the core that were not known when Gutenberg began hi researches, have shown that only a trifling correction is needed to Gutenberg's early result. It is somewhat invidious to attempt to single out any one topic from the vast array of subjects on which he worked in later years, but mention should be made of the important impact produced on geological and geophysical science by the long series of studies, made jointly with C. F. Richter, of the magnitude and distribution of earthquakes, a work that has given an enormous impetus to the study of the seismicity of the Earth.

Beno Gutenberg was born in Darmstadt on June 4, 1889. His training at the University of Gottingen afforded him the best possible ground-work at that time in the young science of seismology. Already well equipped with a wide and deep pre-university education, he attended mathematical lectures by Hilbert, Klein, Minkowski, Landau, Born, Wiechert and Weyl. In geophysics he worked on microseisms under Wiechert, who indeed covered in his lectures a wide range of geophysical studies. Jointly with Geiger, Gutenberg developed the Zoppritz method of using the amplitudes of seismic waves to study the internal structure of the Earth, and received his Ph.D. degree in 1911 at the age of twenty-two. After a further year of advanced study, during which he completed his paper on the Earth's core, and a year in the Army, Gutenberg was appointed assistant at the International Seismological Central Station at Strasbourg, which at that time was in Germany. In 1924 he became director of the Feldberg (Taunus) Seismic Observatory of the University of Frankfurt, at which University he later became a professor. During these years, in addition to the heavy load of observation, writing and teaching, he directed the family business inherited from his father.

In 1931 he was appointed professor of geophysics and meteorology in the California Institute of Technology, Pasadena; here he played a notable part in the development of the Seismological Laboratory, of which he was director from 1947 until his retirement in 1957.

In later years honours fell thick upon him, both from European and from American academies. During 1951–54 he was president of the International Association of Seismology and Physics of the Earth's Interior.

Gutenberg was a kindly man, ever ready to help a fellow scientist and to indulge in a scientific *tête-à-tête*, and his accurate and retentive memory made him a pleasant and interesting companion. Visitors to Pasadena received a warm and hospitable welcome from Prof. and Mrs. Gutenberg; theirs was indeed a happy and cultured home. Gutenberg had a large collection of records of classical music, and those visitors who shared his taste appreciated the privilege of the musical intimacy that he so freely extended. To the last his powers of original work remained unimpaired; seismologists will mourn the loss not only of a great man but also of a valued friend.

R. STONELEY

Dr. Otto Schindler

DR. OTTO SCHINDLER, who died suddenly on September 4 at Poitiers, while on a collecting expedition, had come to occupy a leading position among the small band of European ichthyologists.

He was born on December 1, 1906, and spent his childhood in Vienna and the Sudetenland. During 1925–30 he studied in Vienna under Versluys and gained his doctorate in 1930 with a thesis on fishery biology. For a short time he worked in the Vienna Museum; but the greater part of his mature work was done at the Zoologische Staatssammlung at Munich, where he attained the rank of *Oberkonservator*.

At Vienna it fell to his lot to describe two species of small fishes collected by Dr. V. Pietschmann over Hawaiian reefs. Although no more than a couple of centimetres long and showing many larval characters, these fishes included ripe males and females. Dr. Schindler directed attention to their pædogenetic characters, but placed them in the genus *Hemirhamphus*. When later Giltay found one in New Guinea waters he formed other views on their relationships and created a genus *Schindleria* and family Schindleriidae for them. More recently, Gosline (1959) made of them a distinct suborder, relating them tentatively, as Giltay did, to the blennies. Schindler himself was stimulated by them to make a comparative investigation of the kidneys of larval marine fishes, for which he paid a special visit to the Plymouth Marine Laboratory to collect material.

Schindler's other fields of interest were the ecology of the freshwater fishes of the Austrian and Bavarian lakes and the fish-fauna of South America. He took part in two expeditions to the latter continent and studied the collections of the early expeditions in Vienna and London. His field book of German freshwater fishes, "Unserer Süsswasserfische" (1953 and 1959), was translated into English and edited in 1957 by Dr. P. A. Orkin.

As a result of Dr. Schindler's initiative and organization the German ichthyologists produced a quarterly "Ichthyologischer Schriftennachweis", a classified list of titles, by which they helped each other to keep abreast of current ichthyological publications. Without his leadership this and much else in German ichthyology come to an end. All who knew him miss a valued colleague and friend. Frau Dr. Schindler, a scholar in another field, is left to mourn him with their daughter and two sons, the eldest just of university age.

E. TREWAVAS

Dr. L. O. Kunkel

LOUIS OTTO KUNKEL, faculty member of the Rockefeller Institute during 1931–49, was actively conducting scientific research in the field of plant pathology at the Institute up to the time of his death on his farm at Newtown, Pa., on March 20.

Dr. Kunkel established the Division of Plant Pathology at the former Princeton, New Jersey, branch of the Rockefeller Institute in 1931 and influenced significantly the growth of knowledge concerning the relationship of viruses to plant diseases. Bringing to his research theoretical knowledge and practical experience in the United States and Hawaii, he conducted research which shed new light on the nature of the virus and also led to new understanding of disease in peaches and other fruits, cranberries, maize and carrots.

Dr. Kunkel helped to foster the work of his associate, Dr. Wendell M. Stanley, who, in conjunction with Dr. John H. Northrop, shared the Nobel Prize in chemistry in 1946 for crystallizing the tobacco mosaic virus. Dr. Kunkel, in administering his laboratory, gave his junior associates a free hand in investigating the cause, transmission, pathology, treatment and prevention of a number of plant virus diseases of great economic importance and theoretical interest.

It was shown for the first time in his laboratory that several different yellows-type diseases (such as the virus disease of asters known as 'yellows') could be cured by heat-treating the plants in which they occur naturally or to which they may be transferred. Various virus diseases of the peach were cured in this manner as well as some virus diseases in cranberry, periwinkle, and the potato.

Dr. Kunkel and his associates discovered the transmission ability of leafhoppers in spreading virus disease, the ability to kill such infective activity by heat treatment, and the restoration of the infective ability to the insect. He charted out carefully the infective ability of various virus strains of such diseases as the tobacco mosaic virus or yellows-type, and demonstrated for the first time how a leafhopper infective for one strain was unable to pick up and transmit the other. He showed how a parasitic plant, the dodder, can transmit virus diseases from woody plants to herbaceous plants in which they are more easily studied. He also demonstrated that peach yellows, one of the oldest and best-known plant diseases, is transmitted by a leafhopper of a certain species. He demonstrated the same kind of transmitting factor for corn stunt, a yellows-type virus disease of maize.

Born in Mexico, Missouri, on May 7, 1884, Dr. Kunkel received the bachelor's and master's degrees from the University of Missouri, and the Ph.D. degree from Columbia University in 1914. He held a travelling fellowship in Europe, served as a pathologist in the Bureau of Plant Industry, U.S. Department of Agriculture, and started to study the virus diseases of plants.

Working with the Hawaiian Sugar Planters Association, he served as associate pathologist to study the problems of mosaic disease of sugar cane. He then became a staff member of the Boyce Thompson Institute in Yonkers, New York, in 1923 and gathered around him a group of young men trained in several fields of scientific investigation. At the Boyce Thompson Institute, Dr. Kunkel made important contributions to our knowledge of the mosaic diseases of tobacco, sugar cane and Indian corn as well as asters yellows.

He was a member of several scientific societies including the National Academy of Sciences, the Botanical Society of America and the American Philosophical Society.

NEWS and VIEWS

New Foreign Members of the Royal Society

THE following have been elected foreign members of the Royal Society: Prof. G. W. Beadle, chairman of the Division of Biology, California Institute of Technology, Pasadena, California, distinguished for his outstanding contributions to genetics; Prof. Ragnar A. Granit, professor of neurophysiology, Kungl. Karolinska Mediko-Kirurgiska Institutet, Stockholm, distinguished for his researches on the physiology of vision and neurophysiology; Prof. G. B. Kistiakowsky, professor of chemistry, Harvard University, Cambridge, Massachusetts, distinguished for his work in chemical kinetics of gaseous reactions, photochemistry, thermochemistry, and structure of polyatomic molecules; Academician L. D. Landau, professor of theoretical physics, S. I. Vavilov Institute of Physical Problems, Moscow, U.S.S.R., distinguished for his contributions to theoretical physics.

The Zoological Society of London: Nuffield Institute of Comparative Medicine

THE Nuffield Foundation has made a grant of £100,000 to the Zoological Society of London to found an Institute of Comparative Medicine, and to provide two senior research fellowships. In expressing its deep gratitude, the Council of the Society has asked that the name of Lord Nuffield be associated with the name of the Institute. The Society already has a modern animal hospital, and the new Institute will provide a much-needed opportunity to increase knowledge of disease in animals, and so to maintain the health of the Society's collections at an even higher degree of excellence than at present. Much unique material from the Society's collections and elsewhere is available for study, and full use can now be made of opportunities for research that have not been fully exploited in the past owing to the lack of the facilities and personnel. A Committee, including Sir Roy Cameron, Dr. E. Cotchin, Mr. R. Fiennes, Dr. R. E. Glover, Prof. A. Haddow, Prof. R. Hare, Dr. L. Harrison Matthews, Mr. J. N. Ritchie, Dr. J. G. Smith, Prof. G. Paling Wright and Sir Solly Zuckerman, has been appointed to advise the Council on the organization of the new Institute, the terms of reference of which are to study disease in all its comparative forms.

Mr. Richard Llewelyn Davies, director of the Nuffield Foundation Division for Architectural Studies, and professor elect of architecture in the University of London, will design the new building in accordance with the over-all plan for the Gardens that has been devised by Sir Hugh Casson in collaboration with Mr. F. A. Stengelhofen, the Society's resident architect. In planning the Institute, it is hoped that effect can be given to conclusions drawn from an exhaustive study of the laboratory designs for which the Nuffield Foundation has been responsible over the past few years.

The new Institute, which it is hoped will be in operation in about two years time, is to be built as part of a new block immediately west of the main offices. It will form the central part of the block, the east wing of which will provide a new meeting room for the Society. The western wing will be added at a later date and will house the Education Centre. It is proposed that the Institute itself will have a frontage of about 85 ft. and a depth of 50–60 ft., and will have a basement, ground floor, and two upper floors. The foundations will be constructed so that an additional floor can be added at a later date if required. The floor area, including the basement, will be about 18,200 sq. ft. Twelve laboratory units each of 300 ft. are planned, with offices, technicians' rooms, photographic rooms, workshops and stores. In addition there will be weighing and sterilizing rooms, a media kitchen, chromatography, balance and other specialized instrument rooms, hot and cold rooms, animal accommodation, seminar and common rooms.

Agricultural Research Council: Weed Research Organization

THE Agricultural Research Council is setting up a new Weed Research Organization which will assume some of the present functions of the Council's Unit of Experimental Agronomy at the University of Oxford. The new Organization has been created for the purpose of extending the applied research which lies between the basic scientific investigations being carried out at the Unit and the introduction of new methods of weed control in agriculture and horticulture. To provide the facilities required to enable the Organization to carry out this work, the Council has acquired a farm near Oxford, where a laboratory and other buildings are to be provided. The director of the new Organization will be Dr. E. K. Woodford, who is at present assistant director, under Prof. G. E. Blackman, of the Council's Unit of Experimental Agronomy. The Organization will maintain close liaison with the Unit, which will continue its main purpose of fundamental research concerning the factors which determine the selective action of compounds toxic to plants.

Nuffield Foundation: Unit for the History of Scientific Ideas

THE Nuffield Foundation has formed a Unit for the History of Scientific Ideas which will produce educational films and books under the direction of Prof. Stephen Toulmin, formerly professor of philosophy in the University of Leeds. A sum of £60,000 has been allocated for the Unit. The Foundation believes that a better public understanding of science would be assisted if discussion of the history of scientific ideas had a larger part in the educational curriculum and in intellectual life generally. A place is being made for the subject at some schools and universities; but there is not enough educational material available at levels suitable for sixth forms and undergraduates. The first aim of the Unit will be to produce a basic collection of teaching films and text-books for use in sixth forms and introductory university courses in the history and philosophy of science.

Before the Unit was conceived, the Nuffield Foundation supported the production by Prof. Toulmin and Miss Goodfield of a colour film "Earth and Sky", which has been well received by educationists. The first two films to be made by the Unit are likely to be on the theory of matter and evolution, and the Hutchinson Group are to publish a series of books under the general title "The Ancestry of Science" covering the same ground as the films. A series of monographs at a more advanced level is also to be published, and some books with colour illustrations for secondary modern schools are also envisaged.

The Textile Institute

IN his presidential address to the Textile Institute at its fiftieth annual general meeting at Leicester on April 22, the Earl of Derby stressed the value of the Institute to the textile industry. This was shown by the way in which the Institute's activities had flourished and its membership been maintained in a period of reorganization when many mills had closed, and it was encouraging to note the interest employers' organizations were now showing in technological education. Management, he said, must be prepared to spend both time and money in making certain that the right number of young men of the proper outlook are encouraged to enter the industry, and trained when in it, or that they would be ready to guide the industry in a future when other countries have developed technical resources equal to those of Britain. This could not be achieved cheaply: the industry must be prepared to invest in men as well as in machinery and it was a matter of vital concern to the industry that a professional man should keep his knowledge up to date and contribute to the development of his technology by playing his full part as a member of the Textile Institute. Lord Derby referred particularly to the technological work undertaken by the Institute, for example, in the preparation of standard methods of test for publication by the British Standards Institution, in the Institute's own publications such as "Terms and Definitions", its *Transactions* and its *Abstracts*. Appealing for more generous support from the industry, he suggested that the income of the Institute could usefully be doubled.

The Wandering British Scientist

IN a written answer to a question in the House of Commons on March 28 as to what steps were being taken to stop the gradual loss of scientific personnel from the United Kingdom to the United States, particularly in view of the number of scientists who had left the Jodrell Bank radiotelescope project, the Minister of Education, as representing the Minister for Science, said that the general problem of emigration of scientific personnel had been under consideration for some years by the Advisory Council on Scientific Policy. Since 1958 steps taken by the Civil Service Commission and the Atomic Energy Authority to recruit British scientists in America had met with some success.

Payment of Scientific Civil Services

State Service of April 1960 contains the annual report for 1959 of the Institution of Civil Servants, issued in readiness for the annual meeting of the Institution at Eastbourne during May 23–25. The year was marked by a 3·5 per cent pay supplement on salaries up to £2,000, the Coleraine Committee's recommendations for the higher Civil Service and their acceptance by the Government, and a 10 per cent increase in night subsistence allowance with the commencement of a review of all subsistence arrangements. The report regrets the apparent downward trend of the status of professional scientific and technical officers in the Atomic Energy Authority, also some steps which might indicate an intention to minimize the role of the Department of Scientific and Industrial Research in scientific research. The Government's attitude to salaries in general is criticized, as is the continued refusal to make any move towards counting unestablished service in full for superannuation purposes. The membership of the Institution on December 31, 1959, is given as 51,632, and the issue notes that the present general secretary will be retiring after the 1961 Conference. Reference is also made to the possibility that technical Civil Servants may take a day off simultaneously in view of their growing impatience at handling pay requests.

Apprenticeship Training in Britain

IN reply to a question in the House of Commons on April 11, the Minister of Labour, Mr. E. Heath, said he is proposing to set up a small number of classes in Government training centres to provide first-year apprenticeship training. This training would only be given to boys accepted as apprentices by firms, and preference would be given to boys from firms which had hitherto found it impracticable to undertake apprentice training or to increase their present number of apprentices. No charge would be made for the training provided, but employers participating in the scheme would be required to undertake to pay the wages of apprentices during the year and to continue the boys' training afterwards under the normal industrial arrangements. The usual provision for day release would apply during the year. The scheme, he said, has been approved as a whole by the British Employers' Confederation and the Trades Union Congress, and the establishment of classes in engineering has been agreed by employers and trade unions in that industry. Mr. Heath said he proposes to extend the scheme to other trades and he is already in touch with the building industry.

The first training places will be available early this summer at eight Government training centres, and he expects to set up classes at other centres later this year, making a total of about 300 training places. The scheme will not in itself make a large numerical contribution to the expansion of training for skilled occupations during the 'bulge' years and is intended primarily to demonstrate a pattern of training which should appeal particularly to the small firms with only limited opportunities for undertaking training themselves. In reply to further questions, the Minister confirmed that the course would be a full-time one for the whole year, except for the normal arrangements for day release. A leaflet has been prepared for distribution to all firms concerned within the range of the Government training centres where training is to be given. It is not a pre-apprenticeship scheme and is governed by normal industrial arrangements. As to expansion, Mr. Heath said that the response from the industries involved must be considered. The first centres are at Aintree, Birmingham, Bristol, Cardiff, Millington (Glasgow), Leeds, Letchworth and Long Eaton. A similar statement was made in the House of Lords on the same day.

Scientific Information News

WITH the second volume, the title of *Science Information News* issued by the U.S. National Science Foundation is changed to *Scientific Information Notes*, which is regarded as more descriptive of its contents. The purpose of the periodical remains unchanged, and No. 1, Vol. 2 (February–March 1960), includes a note on the work to be undertaken by the Association of Special Libraries and Information Bureaux in Britain on the comparative efficiency of four indexing systems with the aid of a grant from the National Science Foundation. The Foundation is also making a survey of the publication practices of American industrial corporations, including some 200 of the largest companies undertaking fundamental research, and the survey data will be processed and analysed by the Foundation's Office of Special Studies.

Press Publicity for Scientific and Technical Conferences

A CONCISE, well-written "Guide to Press Arrangements for Scientific, Medical and Technical Conferences" has been prepared by the Association of British Science Writers, and is being distributed by the British Association for the Advancement of Science, 18 Adam Street, Adelphi, London, W.C.2. (Pp. 31, 2*s*.) Edited by Ronald Bedford, the pamphlet deals successively with the impact of the Press on the public and on business; general points such as what journalists expect, the functions of the press officer and the various types of conference; the varied types of press representatives who may be present, such as the news agency reporters, journalists from the national and the evening newspapers, radio and television reporters, and the representatives of technical journals, the local press, the foreign press and free-lance journalists. A section outlining the organization required follows, which centres on such details as the equipment of press rooms and the arrangement of press conferences and briefings. There is a section on press summaries and finally some suggestions are collected for the guidance of the press officer.

Manchester Public Libraries

THE one hundred and seventh annual report of the Manchester Public Libraries Committee, covering the year ended March 31, 1959, records a continuing increased demand: issues from the lending libraries rose to 5,675,301 volumes, from the reference libraries to 1,226,183 volumes, and the total book stock is now 1,152,827 volumes (pp. 28 + 4 plates. Manchester: Manchester Public Libraries, 1960). Considerable work was carried out on the Great Hall, the Technical Library, the Commercial Library and the Central Lending Library but the increased seating in the reference library did little to diminish overcrowding. Seating in the Technical Library was more than doubled and the number of volumes on the open shelves was increased from less than 8,000 to more than 25,000, while a lending section was added. There was a pronounced increase in information work and inquiries, and 459 books were supplied to other libraries, mainly in the north-west of England, and 128 books were obtained from outside sources.

Scientific Techniques in the Conservation of Paintings

IN his recent lecture to the Royal Society of Arts entitled "Scientific Methods in the Care of Works of Art", Mr. F. I. G. Rawlins, recently scientific adviser to the Trustees of the National Gallery, reviewed the advances that have been made in the application of scientific techniques in the conservation of paintings during the past twenty-five years. The basic problems, from the point of view of the scientist, are largely those of chemical physics, because the materials of painting are essentially of a colloidal nature, and the process of cleaning which involves the diffusion of solvents through films is itself a lesson in chemical physics. The physical techniques discussed were soft X-rays (that is to say, at about 10 kV.) which give improved results when thin paint-films are being examined, and infra-red photography, which may often reveal an image of what lies under discoloured varnish. On the chemical side, reference was made to improved methods for the preparation of paint cross-sections, and development in the National Gallery of a special reversed-phase system of chromatography as a method of analysis for paint media. The importance of fundamental research was emphasized. As illustrations of this kind of work, reference was made to experiments being carried out to develop picture varnishes having a longer life than the traditional varnish based on natural resins, and also the precise action of solvents on paints and varnishes which is in principle fundamental to a proper understanding of the processes involved in the cleaning of pictures and other painted objects. Mr. Rawlins also pointed out that international co-operation in this field has substantially improved, as is exemplified by the increasing influence and activity of the International Council of Museums, the foundation (in 1950) of the International Institute for the Conservation of Historic and Artistic Works, and the recent formation of the New International Centre in Rome.

Fluoridation of Drinking Water

THE attitude of different countries to fluoridation of water as a means of preventing dental caries has been described by Gerald H. Leatherman and J. A. Ellis, secretary-general and his assistant, respectively, of the Fédération Dentaire Internationale (*Health Educ. J.*, 17, No. 3; 1959). The majority of health authorities throughout the world are in favour of fluoridation. They include: Austria, although a few State authorities are undecided; Canada; Great Britain, where the Government has gone on record through the Minister of Health approving fluoridation as a proved method of prevention; Greece; the East German Democratic Republic; Hong Kong; Republic of Ireland; New Zealand, where the Department of Health is campaigning for fluoridation and the Minister of Health has publicly stated his support of fluoridation, although the Government has made no pronouncement either for or against the measure; Norway; Spain; the United States; and Yugoslavia (Republic of Slovenia), where the political, as well as health authorities, are financially supporting fluoridation and propagating it.

In the main, the following countries support fluoridation: Australia, Belgium, Czechoslovakia, Northern Ireland, Italy, Switzerland, and the Union of South Africa. The following countries are undecided: Denmark, Egypt, Finland, France, Japan, Hungary, Netherlands, Sweden. Opposed to fluoridation are the German Federal Republic, where the health authorities consider the addition of fluorine as dangerous, as fluorine is only harmless in small quantities and there exists a possibility of overdosage as a result of human incompetence; Indonesia, where there are no experts to supervise fluoridation of drinking water and insufficient personnel to practise fluoridation by the topical application method, while only a few big cities have a central water supply; in Latin America as a whole, there appears to be an absence of initiative on the part of many health authorities, as well as the absence of any movement to stimulate the interest of the municipalities.

Biological Standardization of Drugs

THE Research Defence Society, 11 Chandos Street, Cavendish Square, London, W.1, has issued a new pamphlet (No. 10, April 1960, pp. 6) entitled "The Use of Laboratory Animals in the Standardization of Drugs". This explains, by means of straightforward questions and answers, what is meant by standardization of drugs, why it is necessary, why animals must sometimes be used, and what legal control is imposed in tests of this kind.

Exhibit of Invertebrate Evolution

A STRIKING exhibit entitled "These are Invertebrates" was opened at the Australian Museum in July 1959. It is 32 ft. long and 9 ft. high, and shows the main groups of invertebrate animals and their relationships to each other traced by a system of fluorescent plastic lines and lights which flash in sequence, some eight hundred light globes and ultra-violet light being used. Labels outline the characteristics of each major group and the scientific and popular names of the individual species are shown. A panel informs the visitor how to use the exhibit. Of the total of 215 species displayed, fifty-five are paintings and forty-three are models.

Photoperiodic Response of Some Tropical Plants

IT was formerly thought that the small variation in day-length in the tropics could have no appreciable photoperiodic effect on native plants. This has now been refuted by Indian work on rice and other plants. E. Njoku of the Department of Botany, University College, Ibadan, Nigeria, has tested whether certain plants are sensitive to photoperiod when grown at Ibadan (latitude 7° 26′ N.) with a day-length varying from 11 hr. 41 min. in December to 12 hr. 33 min. in June (Njoku, E., "The Photoperiodic Response of Some Nigerian Plants", *J. West African Sci. Assoc.*, 4, No. 2, 99; August 1958). The plants used fell into two main groups, day-neutral and short-day plants. No long-day plants were found. The results suggested that some plants had a critical day-length of less than 12 hr. Others flowered in 12 hr. but not 14-hr. days, indicating a critical day-length between 12 and 14 hr. A critical photoperiod of 12 hr. or less would make it possible for day-length to control flowering at the latitude of Ibadan.

Using day-lengths of 11½–12½ hr., that is, the extremes of day-length at Ibadan, it was shown that late okra (*Hibiscus esculentus*) and *Sphenostylis stenocarpa* showed a critical day-length of less than 12½ hr., and hence did not flower in the long 'summer' days at this latitude. Early okra and *Phaseolus lunatus*, on the other hand, flowered in both 11½-hr. and 12½-hr. days as well as in the natural day-length, but their response was quantitative in nature, the time to flowering being longer in the longer days. In order to test the effect of natural changes in day-length, successive monthly plantings were made in the field throughout the year. The results support the conclusions drawn from the experiments in which day-length was artificially controlled. Hence the photoperiodic response is of practical significance in the latitude of Ibadan. Plants of both groups grown under field conditions showed a marked shortening or lengthening of the vegetative period as the natural photoperiod decreased or increased. A difference of 15 min. may mean flowering or only vegetative growth.

Geology in the U.S.S.R.

AN announcement of forthcoming publications issued by the Academy of Sciences of the U.S.S.R. lists 120 books on geology to be published in 1960, excluding periodicals, popular works, and reprints. Much the same order of output appeared last year from the State Publishing House for Geological Literature ("Gosgeoltekhizdat"); and taking into account the production of other agencies, it seems likely that the geological monographs and text-books published within the U.S.S.R. now number close on five hundred volumes annually. Since much of this literature is little known in the West, a special interest attaches to a paper by Prof. S. I. Tomkeieff on "The Progress of Geology in the U.S.S.R." (*Liverpool and Manchester Geological Journal*, 2, 474; 1960).

This gives the first reasonably full account in English of the extensive geological work which has been conducted in the U.S.S.R., describing the organization of teaching and research and giving brief notes on progress in the various branches of the science. Although the scope of his short paper is immense, Prof. Tomkeieff brings to it a lifetime study of Russian literature, with the result that he opens new avenues to all geologists who are prepared to surmount the language barrier.

Magnetic Annealing

THE phenomenon of magnetic annealing, that is to say, the production of directional properties in a homogeneous alloy by allowing it to cool from a high temperature in the presence of a strong magnetic field, is well known from the early experiments of Bozorth and Dillinger on soft magnetic materials and those of Oliver and Shedden on hard ones. But the reasons for the establishment of such magnetic anisotropy have always been somewhat obscure. According to an announcement issued by the Bell Laboratories, recent experiments have thrown some light on the problem in the case of permalloy, which is in great demand in the form of fine tapes in electronic memory devices, where their switching times under suitable conditions are very short. The new experiments indicate that the magnetic annealing is not effective unless about 14–20 parts of oxygen per 10^6 are present in the permalloy, and there is little beneficial change in increasing the oxygen content beyond these limits. While the mechanism by which the oxygen acts is not clearly understood, it is suggested by Heidenreich, Burbank and Nesbitt that atoms are deposited on a crystal stacking plane at high temperatures, and so result in a displacement or dislocation of the next plane of atoms in the alloy. Whether this suggestion is correct or not, it certainly appears that close control of oxygen content is necessary.

A Commercial Thermoelectric Cold Box

IT is well known that many firms in Great Britain, the U.S.S.R. and the United States of America are working on the development of a practical form of thermoelectric refrigeration; also that the General Electric Co., Ltd., at their research laboratories at Wembley, have carried out extensive investigations on the fundamental properties of bismuth telluride and other semiconductor compounds. It is therefore not surprising to learn in a recent announcement that the Company has now produced what is claimed to be the world's first prototype model of a commercial design of thermoelectric cold box. The box is about 1 ft.^{3} in size and has a drop-down door. The Peltier effect is used for the production of cold, the cooling power of about 0·25 W. taking place at one junction of the thermocouple through which a direct current of 5–10 amp. is passed. The drop in temperature in the enclosure is 20–30 deg. The practical stage of development has been reached by the production of efficient semiconductor thermocouples and a form of construction which provides adequate thermal insulation between the hot and cold sides of the couple. The advantages of the system are lightness, the absence of moving or wearing parts, silent operation and the avoidance of chemical refrigerants. It can operate from a low-voltage battery d.c. supply, such as a motor-car battery, and the prototype cold box fits easily into the boot of a car.

The Wellcome Trust: Grants for Medical Research

THE Wellcome Trustees have announced that among the grants made during the half year ended February 29 were: £120,000 to King's College, University of London (Prof. J. T. Randall), towards the purchase of the lease of premises to house a Department of Biophysics; £70,000 to the University of Toronto (Prof. C. H. Best), to build and equip basically additional research accommodation in the Charles H. Best Institute; £15,000 to the Johns Hopkins Hospital, Baltimore (Prof. A. McGehee Harvey), to adapt premises in the Department of Medicine as a research laboratory for studies of the heart and blood vessels in man, especially by the method of X-ray cinematography; £30,000 to University College, London (Prof. P. B. Medawar), to build and furnish a research unit in cellular immunity as an annexe to the Department of Zoology; £8,000 to the University College of the West Indies, Jamaica (Prof. J. Waterlow), to purchase a mass spectrometer for use in the Medical Research Council's Tropical Metabolism Research Unit; and £2,500 per annum for up to five years, to Prof. A. St. G. Huggett, St. Mary's Hospital Medical School, London, to provide technical assistance and research expenses for work on the physiology of pre-natal growth.

Senior Research Fellowships of the U.S. Public Health Service

THE U.S. Public Health Service has announced that it will award twenty-one five-year senior research fellowships to scientists in eighteen universities and schools of medicine in thirteen States. Cost of the awards for the first year will amount to 260,562 dollars. No maximum stipend is set by the Public Health Service for these fellowships. Instead, each institution requests an amount for the stipend in accordance with its policy. The institution also receives 2,000 dollars a year towards research and travel expenses connected with the project. This is the fourth year of a five-year Federal programme to increase man-power for research in the pre-clinical sciences. The programme is administered by the Division of General Medical Sciences of the National Institutes of Health. The awards are designed principally for the partial support of promising young scientists sponsored by preclinical departments in the period between the completion of their postdoctoral research training and their eligibility for permanent academic appointments. In special circumstances, senior scientists may be awarded these fellowships to supply needed strength in preclinical science departments of schools of medicine, dentistry and public health.

First International Congress on Automatic Control

As the British member body of the International Federation of Automatic Control, the British Conference on Automation and Computation has, during the past year, selected 28 papers to form the British contribution on the subject of automatic control for presentation at the first International Congress on Automatic Control in Moscow during June 27–July 7. The arrangements for this Congress are being undertaken for the Federation by the U.S.S.R. National Committee for Automatic Control. The total number of papers to be presented is 282, and 20 countries are represented. The leader of the British delegation is Mr. John F. Coales of the

University of Cambridge. Further information can be obtained from the Honorary Secretary, Group *A*, the British Conference on Automation and Computation, c/o The Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1.

Autonomics Division, National Physical Laboratory

THE name of the Control Mechanisms and Electronics Division of the National Physical Laboratory is to be changed to the Autonomics Division. The Division is already well known in the field of automatic control and in pioneering digital computers. Such machines are deterministic in that their behaviour can be predicted from their design and their environment, and they can be designed only after a detailed mathematical analysis of the factors involved. By working closely with biologists in studying the methods which living physical systems use to achieve control, the newly named Division hopes to discover underlying principles on which machines that can improve their own performance can be built.

The Royal Institution

AT the annual meeting of members of the Royal Institution held on May 2 the following officers were elected: *President*, Lord Brabazon of Tara; *Treasurer*, Mr. W. E. Schall; *Secretary*, Sir Harold Spencer Jones; *Managers*, Dr. T. E. Allibone, Dr. H. D. Anthony, Mr. E. R. Davies, Dr. A. G. Gaydon, Dr. H. Heywood, Brigadier H. E. Hopthrow, Mr. L. B. W. Jolley, Mr. P. H. Schwarzschild, Wing-Commander H. F. Tiarks and Prof. W. D. Wright; *Visitors*, Mr. A. D. R. Caroe, Mr. A. H. Ewen, Mr. G. J. Gollin, Mr. S. Rees Jones, Mr. W. C. Lister, Miss C. M. McDowell, Mrs. J. E. Milton, Mr. F. Allen Mitchell, Dr. A. A. Moss and Miss D. Sidebottom.

Royal Meteorological Society: Awards for 1959

THE following awards were announced at the annual general meeting of the Royal Meteorological Society: *Buchan Prize for* 1955–59, Dr. R. J. Murgatroyd; *Hugh Robert Mill Medal and Prize for* 1959, Dr. B. J. Mason; *Darton Prizes*, (*a*) *Home Awards*, first prize to Dr. C. J. Adkins and second prize to Dr. J. A. Funk; (*b*) *Canadian Awards*, first prize jointly to Mr. R. H. Douglas and Dr. W. Hitschfeld, and second prize to Mr. D. K. A. Gillies.

University News: Cambridge

THE Fellowship Electors have made the following appointments to Churchill College: Official fellowships: Dr. F. H. Hahn, fellow from October 1 and College lecturer in economics from October 1, 1961; Dr. D. J. Thouless, fellow and College lecturer in mathematics from October 1, 1961. Extraordinary fellowship: Dr. F. H. C. Crick, from October 1. Overseas fellowship: Prof. S. B. Treiman, associate professor of physics, Princeton University, from October 1.

London

THE following appointments tenable at Westfield College have been announced: Dr. E. H. Bellamy, senior lecturer in the University of Glasgow, to the University chair of physics; Dr. E. H. Sondheimer, reader in applied mathematics at Queen Mary College, to the University chair of mathematics; Dr. G. E. Fogg, reader in botany at University College, London, to the University chair of botany.

Announcements

THE Holweck Medal and Prize, given jointly by the Société Française de Physique and the Physical Society, has been awarded to J. Brossel, in recognition of his distinguished work on spectroscopy The presentation will be made on May 11 in the Clarendon Laboratory, Oxford, after which M Brossel will deliver an address (in English) on "Optical Detection of Nuclear Magnetic Resonance".

DR. M. TORDOFF, associate editor of the *Journal of the Textile Institute*, is to become editor of the *Journal of the Society of Dyers and Colourists*. He takes up his new appointment in August.

APPLICATIONS are invited from members of the British Mycological Society and heads of departments for grants from the Cheesman and Pethybridge funds to enable students of mycology to attend the Spring or Autumn Foray, or the Plant Pathology Field Meeting. Grants will be made only to students who would otherwise be unable to attend these meetings on financial grounds. Applications should reach the secretary, Dr. J. G. Manners, Botany Department, The University, Southampton, not later than May 10.

THE Department of Chemical Technology of the Bradford Institute of Technology is organizing a symposium on Co-ordination Compounds: their Chemistry and Applications during May 20–21 Further information can be obtained from Mr. G. J. Weston, Institute of Technology, Bradford.

AN international colloquium on Sub-aquatic Medicine is to be held by the "Club Alpin Sous-Marin" at Cannes during June 15–19. Further information can be obtained from Dr. J. Ferrari, "Club Alpin Sous-Marin", 10 Place Commandant-Lamy, Cannes (A.-M.).

L'ASSOCIATION des Ingénieurs Electriciens sortis de l'Institut Electrotechnique Montefiore is to organize an international information day about nuclear energy in Liège on June 9. Further information can be obtained from Mr. A. Biron, the secretary of the Association, at 31 rue Saint-Gilles, Liège, Belgium.

THE twenty-fourth congress of the International Association for the Protection of Industrial Property will be held in London during May 30–June 4, under the presidency of Sir John Hanbury-Williams, chairman of Courtaulds, Ltd. Further information can be obtained from the secretary of the Organizing Committee, H. C. Miller, 16 St. Martin's Le Grand, London, E.C.1.

A JOINT meeting of the Biochemical Society and the Société de Chimie Biologique in the Faculté de Pharmacie, Avenue de l'Observatoire, Paris 6e, during May 27–28, has been arranged. Further information can be obtained from Dr. W. J. Whelan, Lister Institute of Preventive Medicine, Chelsea Bridge Road, Chelsea, London, S.W.1.

W. H. FREEMAN AND CO., LTD., Hyde House, West Central Street, London, W.C.1, state that they are now the English publishers of Gilluly, Waters and Woodford "Principles of Geology" and of Sawyer "A Concrete Approach to Abstract Algebra", noted in *Nature* of April 2, pp. 57 and 69; the English prices are now 42*s*. and 7*s*. 6*d*., respectively.

POLYMERIC PROGRESS

FIVE hundred people attended a conference on Polymeric Progress held by the Plastics Institute during March 30–31. This figure was limited by the capacity of the William Beveridge Hall of the University of London, and many applications had to be refused. A speaker at the conference dinner pointed out the double meaning of the title, with its appropriate recognition that progress in polymer science and technology is so many-sided that it can be appropriately described as polymeric.

Following an introductory address by J. R. Whinfield, the conference took the form of eight papers, each of approximately forty-five minutes, followed by thirty minutes for questions and discussion. The diverse interests of members of the audience inhibited any detailed discussion and the question periods were for the most part used in clarifying and amplifying the papers. Each of these was an individual contribution, but for the purpose of this report they may be conveniently grouped.

The most dramatic of recent advances are concerned with the development of new methods of polymerization offering a high degree of control over the structure of a polymer. The effect of this on the physical properties of the polymer can be seen by reference to a few examples: (1) Polyethylene has become a well-known material in many household goods, characterized by toughness and flexibility, with a melting point of about 108° C.; the newer techniques give a much more rigid product, melting at 130° C. (2) Polymethyl methacrylate is familiar as the glass 'Perspex'; two new crystallizable forms have now been produced. (3) Naturally occurring polyisoprenes have long been known—natural rubber and gutta percha; essentially identical products have now been made synthetically, together with other crystallizable products.

The nature and the mechanisms of these new processes were the subject of a paper by G. Gee, in which several levels of structural control were recognized. The terms isotactic, syndiotactic and atactic, originally proposed by G. Natta, have now been widely adopted to indicate the sequence of stereochemical configuration along a polyvinyl chain $-(CH_2-CHX)_n^-$. If the configuration of all the tertiary carbons are identical the polymer is isotactic; if configurations alternate regularly the polymer is syndiotactic; in an atactic polymer configurations are random. The configuration of each carbon is established as the unit is attached to the chain and it is clear that in general the two configurations will differ in probability: it is by control of these probabilities that the new procedures determine the product.

The simplest method of control uses low-temperature catalysts to favour the lower-energy configuration—generally syndiotactic. As the polymerization temperature is lowered, the degree of stereochemical regularity increases continuously and ultimately becomes sufficiently great for the polymer to crystallize. It has been suggested that polymer conformation in solution may sometimes be important: once a regular sequence is established (by chance) the polymer may tend to take up a regular conformation (for example, a helix) in which the same mode of addition is favoured.

The most remarkable of the new catalysts are metal alkyls or products derived from them. Especially noteworthy are the lithium alkyls and the Ziegler catalysts (typified by a combination of titanium trichloride and an aluminium alkyl). The three features which here seem important are highly polar metal–carbon bonds, metal atoms such as aluminium with a strong co-ordination tendency, and solid ionic surfaces. Almost all the most remarkable achievements in stereospecific polymerization so far reported have involved the use of heterogeneous catalysts. A particularly interesting system is found in the polymerization of propylene oxide by metal alkoxide catalysts, where the production of crystalline polymer is stimulated by partial hydrolysis of the alkoxide, giving condensed chain structures which reach their optimum efficiency just as they are on the verge of precipitation from solution.

The use of Ziegler catalysts was considered in more detail in the paper by G. Bier, who reported that the properties of nominally similar catalysts are highly dependent on the method of preparation. It is generally agreed that polymerization on these catalysts involves interpolation of successive molecules of monomer between metal (M) and polymer chain (P), which may be written formally:

$$M \ldots P + CH_2 : CHX \rightarrow M \ldots CH_2.CHX.P$$

Various processes can lead to removal of the polymer which then ceases to grow and is replaced by a new chain, for example,

$$M \ldots CH_2.CHX.P \rightarrow M \ldots H + CH_2 : CX.P$$

Bier presented evidence of the preparation of catalysts in which such processes can be reduced to negligible proportions. In these circumstances it becomes possible to synthesize block copolymers $(CH_2CHX)_{n_1}(CH_2CHY)_{n_2}(CH_2CHX)_{n_3} \ldots$ by supplying two (or more) monomers successively to the catalyst. Copolymers of ethylene and propylene containing 10–20 blocks per chain have been made in this way and show physical properties generally quite different from those of either mixtures of the two polymers or random copolymers. A striking feature of these block copolymers is that all appear to be crystalline, though the crystal structure is unknown.

In the paper on "Acetal Polymers", W. H. Linton described another development in which a familiar monomer has been polymerized in new ways to produce a polymer the properties of which are such as to make it, from the engineer's point of view, a new material. The polymerization of formaldehyde is mentioned in elementary text-books, but stable high polymers have only recently been produced, and marketed as 'Delrin'. Linton described this material as an essentially linear polyoxymethylene with a density of 1·425 at room temperature and a crystal melting point of 180° C. It was stated to be usable continuously at 60–70° C. or intermittently at 100° C. Compared with older formaldehyde polymers, its high stability appears to be due in part to chemical treatment to remove terminal hydroxyl groups, and partly to the high degree of crystallinity consequent upon its very regular structure.

Another group of new-old materials was described by H. Schnell, in his paper on polycarbonates. Intensive earlier work on polyesters had failed to produce any polycarbonates of satisfactory stability and useful physical properties. Two factors which combined to open up this new field were the production of 'bisphenol *A*' $HO.C_6H_4.CMe_2.C_6H_4OH$ and its conversion to a polycarbonate by reaction with phosgene. It proved possible in this way to obtain polymers of high molecular weight which were crystalline and melted above 200° C. Subsequent work has led to the synthesis of many polymers of the general structure $—(OC_6H_4.X.C_6H_4O.CO)_n—$, where X may be $—CR_2—$, $—O—$, $—S—$, $—SO—$, $—SO_2—$. These are broadly similar in physical properties, an attractive feature being high impact strength. The polymers are all crystalline, generally melting above 200° C.; but a high degree of transparency shows that the crystallites must be small. Moreover, the fact that many of these materials are soluble in organic liquids at room temperature is surprising having regard to their high melting points.

The relation of melting point to chemical structure was discussed by H. C. Raine in his paper on polyolefins. Following the pioneer work of G. Natta, a range of 1-olefins have now been polymerized to crystalline polymers which are generally described as 'isotactic'. Raine emphasized that the ability of a polymer to crystallize is not a sufficient proof of 100 per cent stereochemical purity. In illustration he presented data on a large series of polypropylenes having melting points ranging from 110–180° C., correlated roughly but not exactly with the estimated percentage of crystallinity. For any discussion of the effect of monomer structure, one should clearly use the highest melting point which has been attained; but there remains some doubt as to whether data available at the present time are all reliable. Following the work of C. W. Bunn, Raine sought to interpret the data in terms of three factors: cohesive energy per unit length of chain, intrinsic chain stiffness and spatial symmetry.

Of these new polyolefins, only polypropylene has yet been developed commercially, but it may well prove that some others may have useful combinations of properties: the high melting points of polyolefins with bulky side groups are particularly noteworthy. The presence of these side groups in an isotactic polymer makes a planar zig-zag conformation of the chain sterically impossible. Crystal structure determinations on a series of polyolefins have shown helical structures to be characteristic. With this in mind, it might well have been expected that if vinyl cyclopropane could be polymerized isotactically, the polymer would show a similar structure. In his account of recent work by the polymer group at Brooklyn Polytechnic, M. Goodman reported that this does not appear to be the case. Vinyl *cyclo*propane has recently been synthesized, and polymerized with a Ziegler catalyst. Preliminary X-ray studies suggest that the crystal structure is a planar zig-zag.

The problem of polypeptide conformation in solution is dominated by the possibilities of hydrogen bonding. Goodman described work in progress on the synthesis and study of a series of short-chain polypeptides (2–12 peptide links). Optical rotation and rotary dispersion are being used as tools to study the competition between intermolecular association and formation of an α helix. In the latter, intramolecular hydrogen bonding occurs between links 1–5–9–13, 2–6–10–14, etc. End effects are naturally important in these short chains, and the interpretation of the results is not yet entirely clear.

Two papers remain to be mentioned: by H. M. Stanley, on "The Impact of Petrochemical Development on the Plastic Industry"; and by N. J. L. Megson on "High-temperature Resistant Materials". These approached the question of new polymers from opposite ends. The industrial development of a polymer is naturally highly dependent on economic consideration, and in these the cost and availability of monomers looms large. The remarkable progress of the petrochemical industry is well known, both in cheapening established products by opening up more direct and economical routes, and in making available on an industrial scale products formerly laboratory curiosities. In his survey of current trends, Stanley gave good grounds for the belief that if a polymer can be shown to be sufficiently worth while, the petrochemical industry will find a feasible route to the necessary monomer.

Megson's paper pointed the need for the development of polymers with new properties. The kinetic heating of high-velocity aircraft and rockets is already creating a demand for materials, both metallic and non-metallic, capable of performing more satisfactorily at higher temperatures than those hitherto encountered, and it is clear that the problems will become progressively worse as speeds rise. There are really two groups of problems, concerned respectively with thermal, oxidative and hydrolytic stability under very severe conditions; and with the physical properties of materials which encounter an exceptionally wide temperature range. Megson stressed the shortcomings of all known polymeric materials, but was naturally less able to suggest remedies. The overall problem is certainly too complex for any simple solution, and progress can only be foreseen over a broad and straggling front. General studies of new types of polymer will certainly have the high-temperature problem in view as an objective. At the same time, specific applications will require individual study to determine the best compromise between design and material. This is one of the areas where one may hope to find advances when the Plastics Institute holds its next conference on polymeric progress.

THE SCIENCE ASSOCIATION OF NIGERIA

THE second annual conference of the Science Association of Nigeria was held in Zaria, Northern Nigeria, during December 15–18. This Association, affiliated to the wider organization of the West African Science Association, has only been in existence for one year. Its membership is recruited from all branches of the teaching profession, from government scientists and from industrial organizations.

The immense developments in Nigeria since the Second World War have given rise to a large increase in the numbers of scientific workers, both African and European. Yet the overall numbers are still grossly inadequate for the country's need in an age of technological expansion. The Association was brought into being for the dual purpose of providing a forum for scientists working in the country and of informing the general public of the role which scientific work is playing in their lives. Already the Association has achieved considerable success. The quality of the papers and the discussions at the present meeting was extremely high, and it gave a picture of a general standard of work and achievement which would have been unthinkable not many years ago.

The most obvious immediate technological needs of Nigeria are in the agricultural and allied fields. It is not surprising, therefore, that a great deal of emphasis was laid on agricultural developments and of the relation of these developments to nutrition. But other subjects were not neglected. The vexed question of the biological effects of radiation—a real issue in Nigeria since the first mention of Sahara atom bomb tests—was dealt with in a most scholarly and authoritative manner. There were brief incursions into the realms of physiology and even of philosophy.

The importance of the meeting, though, really lay in that it brought together workers from many parts of Nigeria and from many fields of work. Physical and intellectual isolation are an ever-present danger in such a vast under-developed territory, and the real necessity is an interchange of ideas and points of view.

This meeting underlined a phenomenon of great significance certainly in Africa, probably also in other territories, namely, a re-orientation in the pattern of research. Before the War the tropics at the best were field stations visited by scientists from Europe, who collected their material for examination in properly equipped laboratories in Europe. To-day, Nigeria not merely has the laboratories—insufficient in number, perhaps, but still there—but also the scientific personnel to carry out the work. The opportunities here are immense, and the challenge is something which Europe cannot match. There is, after all, a fundamental absurdity, justified at the time they were created, in institutions of tropical research situated in England or indeed anywhere outside the tropics. This alone is a big development. Most of the original work carried out in Nigeria is, perforce, in applied subjects such as agriculture and medicine. Nevertheless, the third step towards scientific maturity has already been taken, for there is now a great deal of 'pure' research being carried out, particularly at the University College, Ibadan.

Science and technology in Nigeria are still young, but one feels that the plant is viable, that scientific activity will continue to grow, and that the nation as a whole will increasingly come to accept the new technologies as her best guarantee of future prosperity.

B. Hopkins

THE SMITHSONIAN INSTITUTION

THE annual report of the Smithsonian Institution for the year ended June 30, 1959, includes the Secretary's report, reports of branches of the Institution, the library and publications, and the financial report of the Executive Committee of the Board of Regents (Pp. x+243+10 plates. Smithsonian Publication No. 4389.) Washington, D.C.: Government Printing Office, 1959). Real progress continued to be made in transforming the museum displays into modern effective teaching exhibits and with 951,608 visitors at the National Gallery of Art, an estimated 4,055,673 at the National Zoological Park, the total number of visitors was 11,358,633. Some 260,000 specific inquiries were handled and 1,144,445 specimens were added to the National Museum, including four collections of Micronesian ethnological material, the entire herbarium of Goucher College, consisting of about 6,100 specimens, the legendary Hope diamond, a superb collection of Chinese jade carvings, more than 7,300 specimens of Carboniferous plants, the Monrós collection of more than 54,000 chrysomelid beetles, and many molluscs and marine invertebrates collected by the Bredin–Smithsonian Caribbean expedition; a collection of early handmade locks, bolts and decorative hardware, and dental instruments, furniture and equipment relating to the history of dentistry. Efforts to acquire early scientific apparatus used in colleges continued, and a group of scientific instruments used by Ira Remsen at Johns Hopkins University was acquired. Field work was conducted by members of the Museum staff in Central America, South America, the Caribbean and many parts of the United States.

Systematic researches by the Bureau of American Ethnology ranged from the River Basin Surveys, Arctic and Eskimo studies, the Seminole and Seneca Indians to archæological work at Russell Cave, Alabama, and progress is reported with the bibliography of the Arctic. The survey parties have now located 4,909 archæological sites in the River Basin Surveys and, of these, 1,017 have been recommended for excavation or limited testing. Work at the Astrophysical Observatory included solar physics, the development of two methods for determining the structure of non-grey stellar atmospheres, a study of atmospheric structure and its correlation with solar activity, studies of the secular acceleration of artificial satellites, meteoritic studies and the design of a telescope for use in space. The satellite-tracking programme continued and the Division of Radiation and Organisms continued its studies on the biochemical changes that occur during the development of the chloroplasts of higher plants. In a study of the lag phase of chlorophyll synthesis it has been shown that X-irradiation of 5–10 kr. can increase the lag phase in etiolated bean leaves, and radiant energy in the region 710–820 $m\mu$ significantly increases the frequency of chromosomal aberrations when used as a supplement to X-irradiation. Accessions totalling 341 specimens in 56 separate accessions to the Natural Air Museums included an early example of a German one-man helicopter, a *DM*-1 delta-winged glider of the Second World War, and many documents pertaining to pioneer rocketry research.

Accessions of 1,286 animals brought the total count at the National Zoological Park to 2,384; about 400 people visited the Canal-Zone Biological Area, including 54 scientists, students and observers using the station's facilities for special researches.

particularly in plant and insect studies, observation of wildlife and photography. The International Exchange Service received 1,129,476 packages, weighing 767,399 lb. of government, scientific and literary publications, and distributed 63 full and 43 partial sets of United States official publications; 85 copies of the Federal Register and 95 copies of the Congressional Record were also dispatched under the Interparliamentary Exchange of the Official Journal. The library received 52,669 publications during the year, bringing its holdings to 982,596 volumes, including 586,722 in the Smithsonian Deposit at the Library of Congress, and arranged 159 new exchanges. Eighty-one publications were issued during the year.

A CENTRAL INSTITUTE FOR SCIENTIFIC CINEMATOGRAPHY

TO find out what services a Central Institute for Scientific Cinematography could render to research and teaching in Great Britain, an inquiry has been carried out by the British Universities Film Council among a representative group of university teachers*.

A questionnaire relating to research was designed with the view of ascertaining, *inter alia*, whether by some method of sharing apparatus, existing facilities could be better used. The views of the research workers were as follows.

Research projects are undertaken with available resources in mind and unless cinematographic equipment already exists, or a grant to buy it is a possibility, cinematographic methods will not be used. Those departments with such equipment are using it most of the time and it is likely only to be available to visiting workers for short times; however, in the majority of instances visiting workers would be welcome, particularly to learn the methods in use. Many who use ciné equipment, and many more who do not do so at the moment, would welcome information concerning equipment available and the ways in which it can be applied to specific problems. This could be one of the functions of a Central Institute.

Another questionnaire was designed to determine how a Central Institute could assist teachers. The general reaction was that film at university level is properly used in showing the student moving phenomena which he cannot, for any reason, see at first hand; film should not be used to show observations or experiments which the student should make himself. Many films available, although they fulfil this criterion, are unsatisfactory for university work because they include theoretical material best dealt with in other ways.

University teachers want short films to illustrate particular points which can be best illustrated by cinematographic methods. This need involves an automatic 'push button' projector which has yet to be perfected and a source of supply of the illustrations.

Until such time as apparatus and illustrations are forthcoming, films will have to be used as at present. Many teachers are not aware of the films available on their subjects; the multiplicity of catalogues and sources of supply, each of which has few, if any, items of university standard adds to this confusion. A more centralized source of information is essential.

While the foundation of a Central Institute which had sections for the making of research films, the loan of equipment and secondment of specialized staff, an advisory service on research problems, the making of teaching films and a comprehensive information service on teaching films would appear one solution to these problems, it would seem that some of the current difficulties might also be solved in other ways. If there were greater recognition of the fact that, in many sciences, cinematographic methods have established themselves as a means of recording events for subsequent analysis, apparatus would be provided on a more liberal scale. Such apparatus requires skilled use, and short courses for training of technicians should be provided, perhaps in colleges of technology in various parts of Britain. If the research problems were tackled along these lines, it might be easier to obtain co-operation with other bodies interested in cinematographic methods in research and avoid the isolation which might result if a central institute for university research alone were set up.

The use of an existing organization for a comprehensive service of information of teaching film might well be considered. This would involve the organization in question receiving an earmarked grant from a government source, the grant being used for the collection, collation and dissemination of information on films available for instruction at university level.

Interest in the use of advanced cinematographic techniques is not confined to university departments; other bodies such as the Research Councils, various Ministries and industry are also concerned. If it proposed to set up an Institute which served all these interests, the universities would make full use of the facilities provided. It may be envisaged that universities would, in particular, be users of an advisory service on the application of cinematographic methods and on technical problems, any short instructional courses on methods whether for scientists or their technicians, and an information service on existing film which could be used for further research or for teaching purposes. University departments might be users of a service for the loan of specialized apparatus although they would wish to be free to apply for grants for the provision of apparatus for their exclusive use as previously. Here there may be a difference between the needs of pure and applied science departments; the latter frequently undertake research of an *ad hoc* nature for which the availability of apparatus on loan might have distinct advantages in that it would encourage a high technical standard in the research film made; much film produced in research in Britain, although adequate for the immediate purpose of the worker, is seen to be of poor quality when shown at scientific meetings, and is also inadequate teaching material.

Bell and C. J. Duncan.) Pp. 24. (Newcastle upon Tyne: C. J. Duncan, Hon. Secretary, The Medical School, King's College, 1960.)

WEIGHT STANDARDS FOR MEN AND WOMEN

IN view of the importance of body-weight to health and longevity, the findings of the Build and Blood Pressure Study, 1959, conducted by the Society of Actuaries of the United States, are of major significance (Metropolitan Life Insurance Co. Statistical Bulletin, Vol. 40 (November–December 1959): New Weight Standards for Men and Women. Fathers are Younger. How Fatal Accidents Occur in the Home. Geographic Variations in Mortality by Cause. Pp. 12. New York: Metropolitan Life Insurance Company, 1959). The study not only contributes new data on average heights and weights according to age but also provides information from which new standards of desirable weight have been developed by the Statistical Bureau of the Metropolitan Life Insurance Co.

The new tables of average weights differ from those which were based on two similar studies of insured persons covering the periods 1885–1900 and 1909–27. For women the new average weights are consistently less than they were in the earlier studies, while for men they tend to be higher than before. Thus, at age 25 the average weight for women is generally 5 to 6 pounds less than that shown in the last study; at the age 35 it is from 2 to 4 pounds less, and at age 45 generally 2 to 3 pounds less. The decrease in average weights of women reflects chiefly their efforts to keep slim and, to some extent, the lighter weight of their clothes. Among men, the increase in average weight, compared with earlier studies, varies appreciably with height. The increase is greatest for short men, amounting to 5 pounds or more at most ages. For men of average height the increase is from 2 to 4 pounds, and for tall men from 1 to 3 pounds, the larger differences being found below the age of 45.

The average weights in the present study rise with advance in age among both men and women, but the pattern differs somewhat for the two sexes. Among men, the averages rise rapidly during the twenties and early thirties, but the rate of increase then slackens off and is very small between the forties and fifties. Among women, the increases in weight with age are fairly steady, but are most rapid between the mid-thirties and mid-forties. The lowest mortality generally occurs among people who are well below average weight. Even among young people, the advantage of a slight degree of over-weight is less pronounced than in earlier studies, and at best can now be considered only a temporary advantage. At the middle and older ages, the results of the new study not only show the disadvantage of over-weight, but also indicate that desirable weights, under current conditions, are somewhat lower than those shown in the tables prepared by the Metropolitan Life Insurance Co. in the early 1940's.

TEMPERATURE CHANGES IN THE ANTARCTIC ATMOSPHERE

DR. H. WEXLER, chief scientist of the U.S.–International Geophysical Year Programme, has published a valuable paper on the subject of seasonal and other temperature changes in the Antarctic atmosphere in the July 1959 issue of the *Quarterly Journal of the Royal Meteorological Society*. His results are based on observations made at U.S. and British International Geophysical Year stations in Antarctica and by the Scandinavian-British expedition to Maudheim during 1950–51.

The variation of temperature with height of the seasonal changes is strikingly different from that over temperate continents. The seasonal changes over Antarctica are greatest in the stratosphere (50–60 deg. C.), moderate at the surface (20–40 deg. C.), and least in the troposphere (10 deg. C.). The effect of the greater cooling of the stratosphere is to destroy for a long period the normal sharp inversion boundary of the tropopause between troposphere and stratosphere. During the sunlit part of the year the stratosphere is heated directly by absorption of solar radiation by the ozone which it contains, and it is cooled during the dark part by loss of heat by radiation from the ozone, carbon dioxide and water vapour, so that the stratospheric temperature falls quickly in autumn and rises very rapidly in spring. The fall of surface temperature is rapid in the autumn as the snow surface cools by radiation. Cloud in the winter causes remarkable increases in surface temperature since it is at a higher temperature than the surface itself and so heats the surface by radiation. An example of an increase of temperature by 30 deg. F. in 24 hr. at the South Pole when cirrus cloud came over is described in some detail. In the summer the snow surface is warmed by solar radiation despite its high albedo. The small temperature change in the troposphere is ascribed to the horizontal influx of warm air from over the surrounding ocean. Reasons are given as to why such advection does not reduce the temperature change in the stratosphere. In the troposphere, and at the surface, there is no marked minimum of temperature a month or so after the winter solstice as there is in temperate latitudes. In Antarctica the temperature drops sharply in autumn and then fluctuates about a low mean until the spring, when it rises sharply again.

The year to year temperature changes in Antarctica are as large as those in the interiors of a continent of the temperate zone, amounting to more than 10 deg. C. in the winter months. Thus, in August 1958 Byrd station in West Antarctica was 13 deg. C. colder than in August 1957.

By comparing recent observations on the Ross Ice Shelf with earlier ones as far back as those of Amundsen in 1911–12, Wexler is able to deduce the secular change of temperature. It is found that the mean annual temperature has risen by 2·6 deg. C. since 1911, which compares with a rise of 6·2 deg. C. at Spitsbergen over the same period.

EFFECT OF TEMPERATURE ON GROWTH IN WEIGHT AND TAIL-LENGTH OF INBRED AND HYBRID MICE

PHYSIOLOGICAL processes of acclimatization to high temperatures have been investigated for a number of organisms, but the effects of temperature on growth have received little attention. It is known, however, that growth in body-weight in the few subjects studied is greatly influenced by external temperature, and that there exists an inverse relationship between temperature and body size. It has also been shown for some organisms that buffering against external environment is better in first-generation hybrids than in inbreds. These considerations were kept in mind in recent experiments carried out by Prof. G. A. Harrison, Mr. R. J. Morton and Dr. J. S. Weiner*.

The material studied consisted of four inbred strains of mice and the six possible hybrids between them. Reciprocal crosses were included. It is shown that growth in body weight is partly determined by environmental temperature (70° F., 61° F. (control) and 90° F.). The weight of young heat-treated mice usually increases more rapidly than that of the controls, but at later ages the latter generally grow more rapidly. The magnitude and direction of the environmentally determined responses depend on the particular genotype.

Growth of F_1 hybrids in the two environments is more similar than the growth of their inbred parents, and differences in hybrid response are smaller than the corresponding inbred differences.

Hybrids in any one environment usually have a smaller variability than homozygotes—indicative of their greater homeostasis. One inbred resembled the hybrids in weight variance and weight responses, and the important conclusion emerges that inbreeding does not necessarily mean marked reduction in somatic fitness. The authors, however, do not put forward any explanation of this circumstance. It is perhaps possible that, as in maize, resistance to inbreeding may be genetically determined.

Growth in tail-length is also in part determined by environmental temperature; the higher the temperature the faster the growth-rate, and the longer the tail. The magnitude of the response again depends on genotype, though maternal environment plays some part. Hybrids have a smaller variability in both environments, and the totality of the evidence supports the hypothesis that the hybrids have a greater developmental flexibility than the inbreds.

SCIENTISTS AND ADMINISTRATION

THE description of the Laboratory of the Government Chemist in *State Service* (40, No. 3; March 1960) is a reminder that Government concern with scientific research is no new thing. Even earlier examples were the Royal Observatory (1675) and the Geological Survey (1835), and later the Patent Office (1852), the National Physical Laboratory (1903), the Medical Research Council (1913), the Department of Scientific and Industrial Research (1916) and the Agricultural Research Council (1916).

Quite apart from research to meet the needs of the Armed Services, Government research must be undertaken in order that the Executive may reach all its decisions on the best possible scientific advice, and in order that aspects of national life for which industry is either unable or unwilling to undertake responsibility shall not be neglected; aspects of such are fire, corrosion, afforestation, river pollution, coast erosion as well as problems in the building, transport and mechanical engineering fields. The new challenge of outer space is also throwing up problems calling for Government initiative in research and co-ordination.

The Institution of Professional Civil Servants believes that not only the scientific needs of government in the modern industrial State, but also the scientific needs of the State itself, can be adequately met only if the government is fully responsible for much research work. But the majority of the administrative class of the Civil Service appears to be proud of its scientific ignorance. This attitude is a grave handicap which could be partially overcome through a leavening of the Administrative Class by a deliberate policy of moving scientists into it.

One major difference between government research establishments and those in industry is that the scientists in the latter frequently have the opportunity to move into production and other fields of management.

In this respect the government service lags behind industry. The introduction of men with a scientific background into executive departments would be of benefit to both. Such scientists should undergo a period of administration to fit them to make a full contribution to the art.

When this type of movement occurs there should be no differentiation, either financially or otherwise, between the scientist-administrator and his colleagues trained in other disciplines. The transfer of scientists to administrative work should not be as if to a higher sphere of activity, but to introduce into administration scientists suitable for administrative duties. To ensure the maximum opportunity to develop and demonstrate administrative ability, much more use should be made of secondment to the headquarters offices of their department at all levels.

Apart from such administrative opportunities, the young scientist could obtain valuable experience in connexion with his own research work if he were encouraged to take an independent view and to express his opinions on his own work and the research programmes of his establishment. Research work is essentially a team activity and can only benefit from free discussion among members of the team. Unhappily, in all too many government laboratories there is little or no consultation of this kind. He should also be encouraged to make outside contacts, both industrial and academic. Among outside activities which should be actively encouraged in government research establishments are those connected with the work of technical schools and colleges, particularly lecturing in their own field. These activities could be of value not only in broadening the experience and outlook of the research workers taking part in them but also, by reason of the contacts brought about, in helping the colleges to understand what is required of them in the changing fields of science and technology.

QUANTITATIVE CYTOCHEMICAL OBSERVATIONS ON A SPECIFIC NUCLEOPROTEIN REACTION IN CELL NUCLEI

By Dr. E. A. BARNARD
Zoology Department, King's College, London, W.C.2

An application of micro-spectrophotometry to a specific protein cytochemical reaction is reported here, forming part of an attempt to understand the significance of a particular bonding observed in nucleoprotein in cell nuclei.

It has been shown[1] that a particular component of the nucleoprotein of cell nuclei can be distinguished cytochemically, by chromogenic reaction with a suitable diazonium hydroxide, after all other diazo-coupling groups in the specimen have been blocked by anhydrous benzoylation. The component responsible for this reaction was identified (in the case of chicken erythrocyte nuclei) as composed of histidine residues in the nucleoprotein. The reaction appears to locate a specific and rather labile bonding between this set of histidine residues in the protein and another set of groups in, or associated with, the nucleic acid.

The conditions for obtaining satisfactory micro-spectrophotometric measurements with this reaction have now been found to be as follows. Freeze-drying is the most suitable method, both on theoretical and empirical grounds. If the cytological preservation is inferior or variable, the staining is decreased or is non-uniform in distribution through the specimen. Sections or smears can be used; but the present results were all obtained on smears of disrupted fresh tissue. Errors due to the cutting of nuclei are thus avoided. It is of interest that freeze-substitution (in alcohols) virtually abolishes the reaction, both in smears and in sections. The smears (on cover-slips) were immediately quenched and frozen-dried in a version of the Edwards and Co. tissue dryer modified for this purpose and incorporating a nitrogen 'cold finger'; the temperature over the smear surface must be uniform (for example, −50°).

The dried smears are fixed in absolute ethanol and treated as previously described[1]. Moisture must be excluded until after benzoylation. Of the naphthols tested, *H* acid (1-amino-8-naphthol-3 : 6-disulphonic acid) gives the best results in the spectrophotometry. The stained, washed specimens are stored in immersion oil (Shillaber's) up to the moment of measurement.

The scanning, integrating micro-spectrophotometer of Deeley[2] was used, with a crushing condenser[3]. This apparatus has been shown to give precise measurements of the Feulgen stain in nuclei[4]. Of several mounting media tried, only glycerol gives technically adequate results, but a slow extraction of the stained component begins to occur after 1–2 days in glycerol.

Frog erythrocytes were used as standard test objects. A uni-modal distribution of the nuclear stain, with small spread (*S.E.* 2–4 per cent) is obtained. Variation between sets of cells in different specimens, prepared from the same blood sample and treated identically, was shown to be insignificant ($P > 0{\cdot}5$). Coupling with tetrazotized dianisidine (0·015 per cent) gives a plateau of maximum stain production for exposures from 14 to 30 min. at 2°. The coupling with *H* acid at the second diazo group shows a plateau over the range 5–15 min. exposure at 2° (followed by warming-up to room temperature for 20 min.). The length of the exposures to ethanol, or of storage in immersion oil prior to measurement, does not affect the intensity.

After a benzoylation period of up to 1 hr., unblocked cytoplasmic stain remains, but after longer periods the cytoplasm is fully blocked, and the nuclear intensity is constant for benzoylation times of 2–20 hr. This confirms the previous conclusion from visual examinations, that the component involved shows a qualitative, and not only a kinetic, difference from other cellular constituents in its behaviour towards benzoyl chloride.

Frozen-dried mouse tissues have been examined (Figs. 1 and 2), using the conditions established for maximum staining. The parenchymal cells of mouse

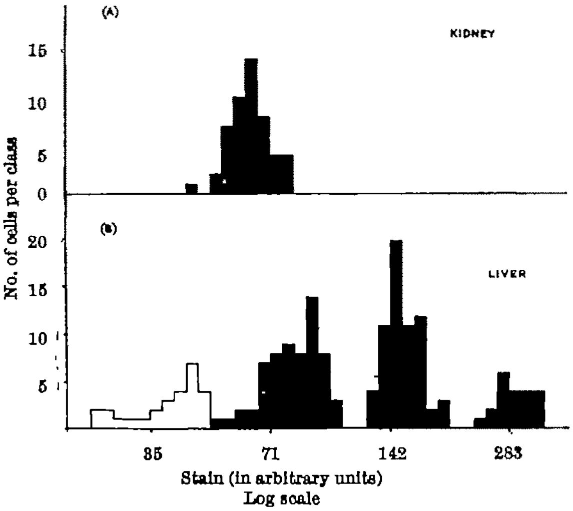

Fig. 1. Distribution of stain in mouse cell nuclei. *A*, typical mouse kidney sample; *B*, typical mouse liver sample; unshaded area, apparent non-parenchymal cells

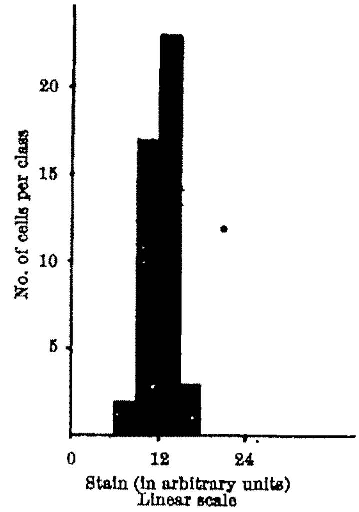

Fig. 2. Distribution of stain in typical sample of mouse sperm

liver show a tri-modal distribution, noticeably similar to that of deoxyribonucleic acid revealed by the Feulgen stain on this tissue[4]. The ratio of the mean values is fairly close to 1 : 2 : 4, and it is presumed that the three classes present correspond to the diploid, tetraploid and octaploid classes of rodent liver. However, an additional class is present here (unshaded area in Fig. 1) with a lower amount of stain. This separate, lowest class appears to consist of non-parenchymal liver cell nuclei (derived from connective tissue, blood vessels, bile ducts, etc.). Some of the larger non-parenchymal nuclei may well be included, however, in the lowest 'diploid parenchymal' class (and possibly *vice versa*), due to difficulties in cell recognition in the smears.

With mouse kidney (Fig. 1) a uni-modal distribution is obtained, again similar to the distribution of deoxyribonucleic acid in the tissue. However, the mean value for kidney does not quite coincide with the 'diploid' value for the stain in the liver of the same animal, and there is a highly significant variation between animals in this kidney value. Samples of kidney tubule cell nuclei from 8 adult mice, maintained under identical conditions (and fed *ad libitum*, stock diet 18, J. Rank Ltd.), each gave distributions similar in form to that shown in Fig. 1*A*, but the mean values ranged from 48·8 (*S.E.* 1·2) to 83·0 (*S.E.* 2·5) units, with a coefficient of variation (C) between animals of 18 per cent. There was no correlation with age between 8 weeks and 6 months. Differences between multiple samples from single animals were insignificant. Standard frog blood smears processed simultaneously with all mouse specimens gave constant results. It is concluded, therefore, that a real individual variation exists in the amount of this component in the nuclei of kidney tubule cells of these animals.

The 'diploid' values for mouse liver appear to lie in a narrower range (72·4, *S.E.* 4·7, to 82·6, *S.E.* 2·8, $C = 6$ per cent), although only 4 animals could be examined. (The present results assume that Beer's law is obeyed, but since the crushing method puts all the extinctions, as actually measured, into the same range, any possible errors are minimized.)

It is clear that the distribution of this nucleoprotein component shows both similarities to, and marked differences from, that of deoxyribonucleic acid. It closely follows deoxyribonucleic acid in intranuclear distribution[1], including location on the chromosomes in mitosis, and similarly in its correspondence with the ploidy classes in liver parenchymal cells ; but the value in sperm is much less than would be predicted on the deoxyribonucleic acid basis (Table 1). Even in somatic cells, however, the amount of this component is not determined by the deoxyribonucleic acid content alone, as can be seen from the results on liver non-parenchymal cells and on frog red cells (Table 1).

Since the liver ploidy classes normally correspond to classes of increasing cell size, a correlation with the latter variable might be suggested. Attention is directed to a correlation, at least for tissues where the required data are available, with the protein content of the nucleus (Table 1). The latter has been determined in mouse tissues on an individual cell basis by means of interferometry by Davies *et al.*[6] ; a fourth, lower class in mouse liver is similarly found. Since nuclei isolated in salt solution were used in those measurements the quantity involved is probably not the total nuclear protein, but a major (and less-soluble) fraction thereof, largely consisting of those proteins associated with the nucleic acid.

It seems likely that the observed variability of the stain in kidney tubule cells, which is in contrast to the constancy of their deoxyribonucleic acid content, is derived from unknown individual differences in physiological or metabolic states. The relative constancy of the stain in sperm heads and in frog erythrocytes, and its variability in kidney tubules, suggest that the component in question is concerned in cellular activity.

Table 1

Species	Cell type	No. of cells measured	Mean stain per nucleus	Relative stain per nucleus*	Total protein per nucleus* (relative)		Deoxyribonucleic acid (in 10^{-12} gm.) per nucleus†
Mouse (*C*57 strain, males)	Sperm	35	11·9	0·15	0·15‡		2·5
	Liver, class 1*A* ‖	39	36·6–41·7	0·50–0·51	0·44‡		5

* Taking liver class 1 mean value as 1·00.

† From combination of data from refs. 5 and 9.

‡ Derived from data of Davies *et al.* (ref. 6), taking total protein as total dry mass of isolated nucleus, less deoxyribonucleic acid and less ribonucleic acid. Ribonucleic acid is taken (somatic cells) as ½ deoxyribonucleic acid (ref. 10), but this correction is, in any event, small.

§ For approximate comparison : data of Alfert *et al.* (ref. 11) on rat liver, by Millon micro-spectrophotometry.

‖ Lowest class, see text.

N.D. = not determined.

It is not, however, inferred that this histidine component is distributed uniformly throughout the nucleoprotein, but rather that the amounts of this component appear to be related to nuclear activities which in turn appear to be associated, perhaps indirectly, with the total nucleoprotein content. It is not yet possible to assign these histidine groups to an identifiable fraction of the nucleoprotein. However, it is of interest that recent X-ray diffraction studies[7] indicate that protein bridges form in the nucleoprotein of the nucleus on drying; these have properties, notably disruption by water, similar to those observed here. A possible interpretation, therefore, is that histidine side-chains (and perhaps others) are involved in these bridges. On this view, the present reaction locates specific sites of potential hydrogen-bonding, situated on certain protein surfaces in the deoxyribonucleic acid-protein complex and related to nuclear activities.

A detailed study of the method will appear elsewhere[8]. I should like to thank Prof. J. F. Danielli for his unfailing interest and encouragement; Prof. J. T. Randall and Dr. M. H. F. Wilkins, for the use of instrumental facilities in the Medical Research Council Biophysics Research Unit, King's College, and Dr. B. M. Richards for valuable help in connexion with the micro-spectrophotometry. Part of this work was aided by the British Empire Cancer Campaign and by the Nuffield Foundation.

COMPARATIVE STUDIES OF YEASTS

By J. A. BARNETT
Low Temperature Research Station, Cambridge

AN attempt is being made in this laboratory to develop improved methods for classifying yeasts. Present knowledge of the many different types of yeast and the methods for distinguishing between them is largely due to the work of the Delft school[1–4] under the influence of Kluyver[5]. This group of workers has developed the first thorough classification of both the sporing and non-spore-forming yeasts[4], the only other major work in any way comparable being that on the classification of the spore-forming yeasts by Kudriavzev[6].

The main divisions in the Dutch classification of yeasts[4] depend on their ability or inability to form spores and on morphology, although some biochemical characteristics are used chiefly for differentiating species[7]. Unfortunately, the factors which influence sporulation in yeasts (except for *Saccharomyces cerevisiae*) are scarcely understood. To make a yeast sporulate it may be necessary to culture it on a large number of alternative media; if, nevertheless, sporulation is not observed, it still does not follow that the yeast is incapable of forming spores. A further difficulty is that it is often impossible to define precisely the morphological criteria used. It is sometimes necessary, for example, to decide whether the buds of vegetative cells "arise on a more or less broad base"[7], whether they have formed pseudo- or 'true' mycelium, whether they are 'lemon-shaped', or whether the spores are "round or oval, reniform, bean- or sickle-shaped, Saturn- or hat-shaped, hemispherical or angular, fusiform or needle-shaped"[7].

The biochemical tests used by the Dutch school were in the first place mainly fermentation tests (that is, ability to produce gas, under fairly low but unknown oxygen tension, from glucose, galactose, sucrose, maltose and lactose[1–4]) and, secondly, growth tests using these sugars as sole sources of carbon[2–4]. In 1948, Wickerham[8] employed additional sugars, as well as glycosides, sugar alcohols, organic acids and other sources of carbon for growth tests, and he applied these new tests, to the classification of the genus *Hansenula*[9]. Kudriavzev[6] has also used many compounds for growth tests and this use of a large number of carbon sources has become popular among yeast taxonomists.

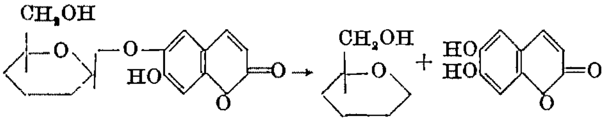
Although the widespread use of these growth tests has increased knowledge of the biochemical potentialities of many kinds of yeast, most of the tests are ill-understood and not carried out under well-defined conditions[10–13]. The Dutch workers have used auxanograms[2–4,10]: yeast cells are inoculated into a molten agar medium which contains all the growth requirements except one, such as a source of carbon; the medium is poured into a Petri dish; alternative carbon sources are placed on the agar surface and the presence or absence of growth observed. Kudriavzev's growth tests were carried out on slopes of medium, each containing a single carbon-source[6]. Wickerham[8,9] used defined liquid media, contained in unshaken tubes to which alternative carbon- or nitrogen- sources or vitamins were added, and the growth response was judged by eye (as for the auxanograms and for Kudriavzev's tests). It is, however, practicable to measure growth in liquid culture by photoelectric methods, using shaken T-tubes which provide uniform growth conditions for the tests[10,14].

As standard biochemical techniques have been introduced, it has become possible to develop a comparative study of yeasts which is based mainly on their biochemistry. In this work, imprecise and subjective morphological observations are avoided and there is no need to search for spores. Work towards this end is being carried out in this laboratory, and it is hoped to develop taxonomic procedures so

Table 1. THE GROWTH OF SOME YEASTS ON CERTAIN POLYOLS

Yeast	Polyol					Reference
	Mannitol	Sorbitol	Galactitol	Ribitol	Erythritol	
Brettanomyces spp. (9 strains)	−	+	−	+	−	20
Brettanomyces spp. (2 strains)	−	+	−	−	−	
Kloeckera apiculata (NCYC 328) *Saccharomyces cerevisiae* (NCYC 77, 176 and 231) *Saccharomyces acidifaciens* (CBS 685 and 739)	−	−	.	−	−	14
Saccharomyces bailii (CBS 680) *Saccharomyces marxianus* (NCYC 111 and 243, CBS 712 and 745)	+	+	.	+	−	

that each test will then reveal the presence or absence of a single enzyme, as suggested by Clarke[17]. For example, according to Wiles[18], *Candida guilliermondii* grows when the coumarin glycoside, æsculin, is the sole source of carbon, but *Candida krusei* does not. Is the reason for this difference that *C. krusei* lacks a suitable glycosidase or that it is poisoned by the æsculetin liberated by hydrolysis[12,14]? Is the same cause responsible for the comparable difference he described between *Hansenula anomala* and *Kloeckera apiculata*? As a further example, yeasts of the species *Saccharomyces cerevisiae* and *Saccharomyces acidifaciens* are unable to use exogenous intermediates of the tricarboxylic acid cycle (for example, malate, succinate, citrate) as sole sources of carbon for growth or respiration, while *Saccharomyces drosophilarum* and *Saccharomyces marxianus* are able to do so[15]. Since this distinction is now used by taxonomists[6,9], it is important to know whether it is due to differences in a major metabolic pathway or whether it reflects some difference of transport mechanism across the plasma-membrane[19], or sometimes the one and sometimes the other. A third example is provided by the work of Wickerham[9], who characterized nine out of fifteen species of *Hansenula* as unable to use erythritol as a sole source of carbon for growth. It is important taxonomically to be aware of three alternative possible reasons for this inability: failure of erythritol to penetrate the plasma-membrane; lack of a suitable dehydrogenase; or lack of a kinase capable of phosphorylating the erythrulose formed from the dehydrogenation of erythritol.

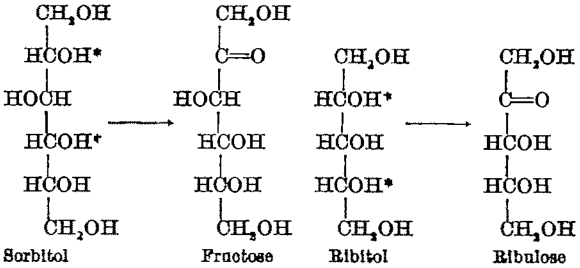


Æsculin (glycoside) Glucose Æsculetin (aglycone)

It has already been possible to throw a little light on some of these questions by working with cell-free extracts and comparing their behaviour with that of intact cells[14]. There are indications that yeasts contain a number of different β-glucosidases and that the phenolic aglycones liberated by their action are inhibitory not only to growth but also to the initial hydrolysis of the glycoside itself[12,14]. There is evidence of the occurrence of the tricarboxylic acid cycle both in yeasts that are capable of using exogenous intermediates of the cycle, and also in those that are not[15]. This makes it likely that the differences between these two types of yeast are in the accessibility of these acids to the enzymes of the cycle.

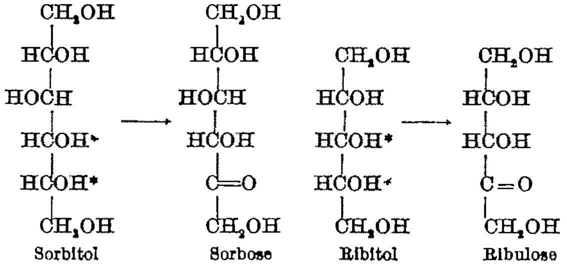
Recent work on *Brettanomyces* species[20] involved a study of their growth on polyols. The results of this work suggest the presence in these yeasts of a polyol dehydrogenase of the type described by Blakley[21,22], capable of oxidizing sorbitol and ribitol, but unable to attack mannitol, erythritol or galactitol. However, recent taxonomic literature[6,9,10,23,24] suggests that Bertrand's D-mannitol dehydrogenase[25,26] is more common among yeasts than the Blakley enzyme. Bertrand's enzyme oxidizes sorbitol, ribitol, mannitol and erythritol (Fig. 1 and Table 1). If the Bertrand enzyme is widespread, the frequent inability of these yeasts to use erythritol could be explained by postulating that it does not penetrate the plasma-membrane. Such suppositions must be checked by work with cell-free extracts, which may show the situation to be vastly more complicated than has been suggested. Meanwhile, it is mistaken to consider sorbitol utilization as a single test when yeasts may be found to possess at least three different enzymes which occur in other organisms and are capable of converting sorbitol to fructose or to sorbose[22,25,27].

The need for understanding the tests used for classifying yeasts has been emphasized from time to time by taxonomists. For example, Wickerham[28] held that the growth tests on various nitrogen sources[2] were spurious because the yeasts could grow on all these sources when given an adequate supply of vitamins; and Kudriavzev[4] considered it important to know whether the enzymes involved in fermentation



Transformations achieved by the Blakley enzyme: L-iditol dehydrogenase

(This enzyme also converts L-iditol to L-sorbose (ref. 22))



Transformations achieved by the Bertrand enzyme: D-mannitol dehydrogenase

(This enzyme also converts mannitol to fructose, erythritol to erythrulose, D-arabitol to D-xylulose (ref. 25).)

Fig. 1. Specificity of two polyol dehydrogenases. (Asterisks indicate arrangement of hydroxyl groups for which the enzyme shows stereospecificity)

tests are adaptive. But very little has been done so far to apply methods of metabolic biochemistry to the study of different kinds of yeast, although the work that has been started along these lines, and has been briefly described above, suggests that it will prove rewarding. Not only should it make it easier to classify yeasts by making the experimental work more precise, it should also help to produce a stable classification if this is devised in such a way that each test is designed to reveal the presence or absence of a single enzyme[13,14,17]. It would also make yeast taxonomy more useful to biochemists and microbiologists in research and industry who want to know the chemical potentialities of each named yeast.

A ROLE FOR THIOL AND DISULPHIDE GROUPS IN DETERMINING THE RHEOLOGICAL PROPERTIES OF DOUGH MADE FROM WHEATEN FLOUR

By R. FRATER, DR. F. J. R. HIRD, H. J. MOSS and J. R. YATES

Departments of Biochemistry and Agriculture, University of Melbourne
and Victoria State Laboratories, Victoria, Australia

IN 1940 it was recognized by Sullivan, Howe, Schmalz and Astleford[1] that thiol groups and disulphide bonds were involved in determining the properties of dough. Due to lack of adequate experimental methods for determining these groupings, the precise connexion remained unknown. Recently, however, there has been a renewed experimental interest in the role of sulphur from the point of view of disulphide exchange reactions[2–4].

We report here some definitive experiments which allow the formulation of a hypothesis that relates strength and elasticity of dough to thiol groups, intermolecular disulphide bonds, and the rate at which they interchange. At the same time, evidence is presented which explains the action of certain improvers in terms of disulphide interchange. The experiments were carried out with one flour only—a commercial, unbleached flour milled from Victorian *F.A.Q.* wheat.

Thiol and Disulphide Content of Flour and Extracts of Flour

Thiol and disulphide groups were measured in the whole flour and extracts of flour by amperometric titration of excess methylmercuric iodide[5]. This reagent was added with the dispersing medium in order to limit oxidation of thiol groups during the preparation of the dispersions. The results are given in Table 1. For convenience the results are expressed on the basis of 300 gm. of flour, as this was the weight used in the rheological experiments. The flour contained 12·5 per cent moisture and 1·41 per cent nitrogen. It can be seen that the flour and both fractions derived from it contain thiol and disulphide groups. Further, only a proportion of the total thiol groups found in the presence of urea are readily available for reaction in aqueous suspension with methylmercuric iodide. It is likely that these thiol groups measured in aqueous suspension more nearly represent those available for disulphide bond exchange reactions. Both saline-soluble and gluten proteins can therefore play acceptor and donor parts in such reactions. It is apparent, too, that the saline-soluble fraction on a nitrogen basis is richer in thiol and disulphide groups than the gluten fraction. As the gluten fraction is less soluble, mobility of protein in

Table 1. THIOL AND DISULPHIDE CONTENT OF FLOUR AND FLOUR EXTRACTS

Thiol and disulphide contents calculated on basis of 300 gm. air-dried flour

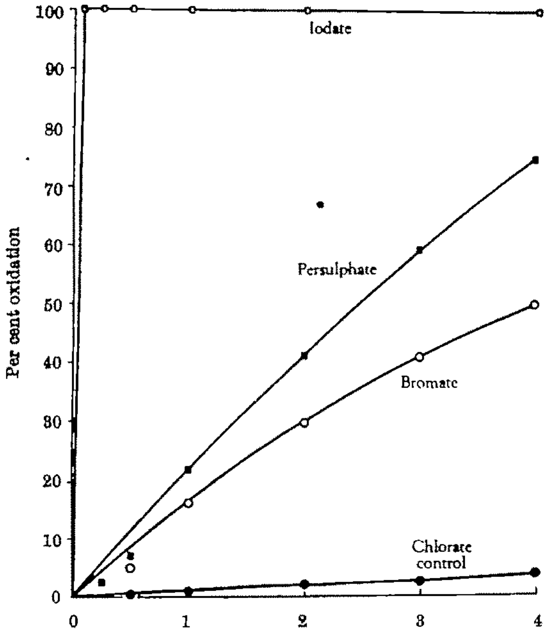

Fig. 1. Oxidation of glutathione by iodate, persulphate, bromate and chlorate plotted against time at pH 6·0 and 28°. Concentration of glutathione, $6·67 \times 10^{-4}$ M; oxidizing agents, 2×10^{-3} M

dough would be due more to the saline-soluble proteins.

Reaction of Thiol Groups with Iodate, Bromate, Persulphate, Chlorate and N-Ethylmaleimide

Oxidation of glutathione, as a model compound, by iodate, bromate, persulphate and chlorate has been followed spectrophotometrically by the method of Boyer[6]. Fig. 1 shows that of the oxidizing agents used, iodate acts very rapidly, bromate and persulphate slowly, and chlorate not at all. Similar results have been obtained with cysteine. Chromatography with phenol/water showed that in the case of cysteine the main product is the disulphide cystine, with small amounts of cysteinesulphinic and cysteinesulphonic acids. Table 2 shows that gluten reduced with sodium borohydride also has its thiol groups oxidized at similar rates by iodate, bromate and persulphate. A full account of the oxidation of thiol groups by iodate, bromate and persulphate is in preparation and will be presented elsewhere. It is of interest that the rates of oxidation of thiol groups by the oxidizing agents used are closely paralleled by their well-known rates of action as improvers in the bread industry[1,7,8].

Table 3 shows that the addition of iodate and N-ethylmaleimide to suspensions of flour brings about a considerable decrease in the readily available thiol groups. In a qualitative way, these decreases support the inferences drawn from the effect of these reagents in the rheological experiments described later. Quantitatively, however, it is likely that, when mechanically mixed, the decrease in total thiol groups of the dough would be greater than that obtained with suspensions of flour.

Table 2. OXIDATION OF REDUCED GLUTEN BY BROMATE, IODATE AND PERSULPHATE

Reduced gluten (10 mgm./10 ml.) finely suspended in citrate buffer 0·5 M at pH 6·0. Oxidizing agent (1·2 mM) added in 1 ml. After appropriate interval, methylmercuric iodide added and excess determined amperometrically. Results calculated on basis of moles/10^5 gm.

Action of Iodate, N-Ethylmaleimide and Cysteine on the Rheological Properties of Dough

The rheological properties of the dough were studied using the commercial instruments—the Brabender farinograph and extensograph. These instruments respectively measure resistance to mixing against duration of mixing, and resistance to extension against distance extended.

Fig. 2 shows that the presence of iodate and N-ethylmaleimide alter the mixing properties of the dough initially in such way as to increase the resistance to mixing and later to lower it. Similar responses on farinograms have been shown by Mecham[9]. The effects of iodate and N-ethylmaleimide are even more marked when measured with the extensograph (Fig. 3). (See also Goldstein[3].)

From the known chemistry of iodate (Fig. 1) and N-ethylmaleimide (Table 3 and Friedmann *et al.*[9]), the effects obtained can be related to the disappearance of thiol groups. In the case of iodate there is the further possibility described earlier, of formation of new intermolecular disulphide bonds which would

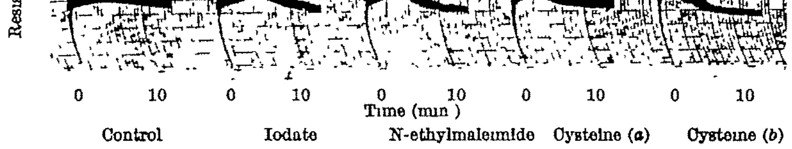

Fig. 2. Farinograms of 300 gm. flour, mixed with 168 ml. water containing 6 gm. sodium chloride and the reagents indicated. Flour contained 450 μmoles thiol and 2,220 μmoles disulphide; iodate, 45 μmoles; N-ethylmaleimide, 150 μmoles; cysteine (a) 75 and (b) 300 μmoles

be expected to strengthen dough. In the case of N-ethylmaleimide, there seems to be only one possible explanation of the effects observed, namely, the disappearance of thiol groups prevents disulphide interchange by removal of one of the necessary components. Expressed in another way, a stable intermolecular disulphide network that does not yield to stress is formed—the result being a tough, non-extensible or stabilized dough.

Figs. 2 and 3 show also that mixing of dough stabilized in this way destroys certain of the bonds responsible for resistance and at the same time increases the extensibility. It follows from these observations that, even in untreated doughs, the rate at which the shearing forces are applied during mixing will affect the rheological properties of the product, depending on the rate at which the exchange reactions can keep pace with the rate at which the stress is applied.

The effect of concentration of iodate and N-ethylmaleimide when mixed with the dough for 1·5 min. is shown in Fig. 4. It is not possible to say whether these two reagents have reacted completely with the thiol groups in the dough under the mixing conditions used but, assuming complete reaction, a rough quantitative estimate (a maximum) of the number of thiol groups involved in the observed effects can be put at 33 per cent of the total thiol groups. With N-ethylmaleimide, the figures, with this proviso, are more certain as this reagent is monofunctional. In the case of iodate, however, there can be no certainty, as the oxidation may proceed within the two extremes:

$$IO_3^- + 6RSH \rightarrow I^- + 3R\text{-}S\text{-}S\text{-}R + 3H_2O \quad (1)$$
$$IO_3^- + RSH \rightarrow I^- + R\text{-}SO_3H \quad (2)$$

However, leaving aside the question of stoichiometry in the reaction between iodate and the thiol groups of flour, its effect is very similar to that of N-ethylmaleimide at similar concentrations.

The effect of adding varying concentrations of cysteine to the dough can be seen in Fig. 2 and Fig. 5. With increasing concentration, strength decreases; and at the higher concentrations the extensibility is so great that the instruments cannot measure the resistance. The figures presented express cysteine added as percentage of total disulphide bonds broken, but reduction in the strength of the dough would be due not only to destruction of intermolecular disulphide bonds but also to an increased rate of their

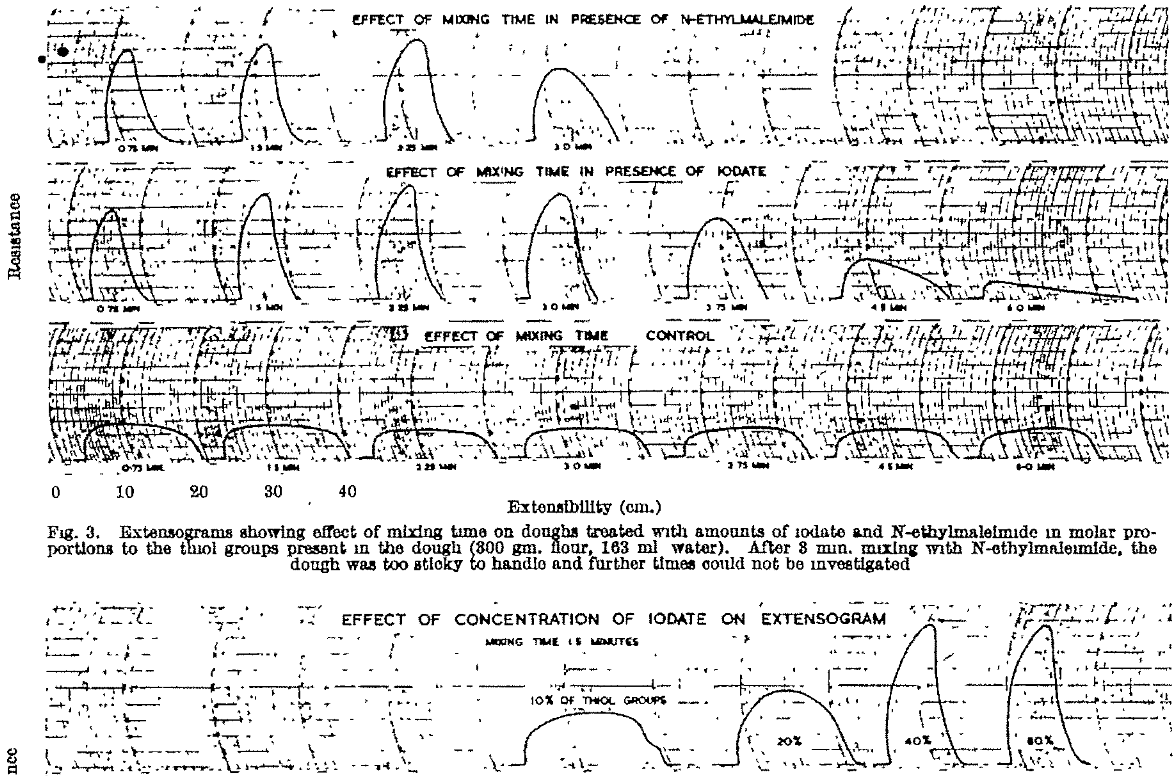

Fig. 3. Extensograms showing effect of mixing time on doughs treated with amounts of iodate and N-ethylmaleimide in molar proportions to the thiol groups present in the dough (300 gm. flour, 163 ml water). After 3 min. mixing with N-ethylmaleimide, the dough was too sticky to handle and further times could not be investigated

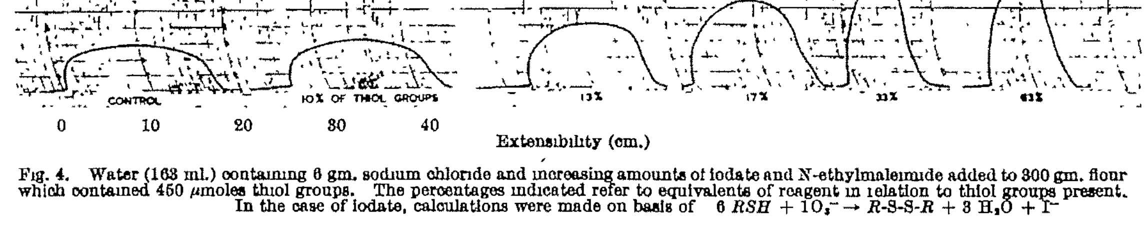

Fig. 4. Water (163 ml.) containing 6 gm. sodium chloride and increasing amounts of iodate and N-ethylmaleimide added to 300 gm. flour which contained 450 μmoles thiol groups. The percentages indicated refer to equivalents of reagent in relation to thiol groups present. In the case of iodate, calculations were made on basis of $6\,RSH + IO_3^- \rightarrow R\text{-}S\text{-}S\text{-}R + 3\,H_2O + I^-$

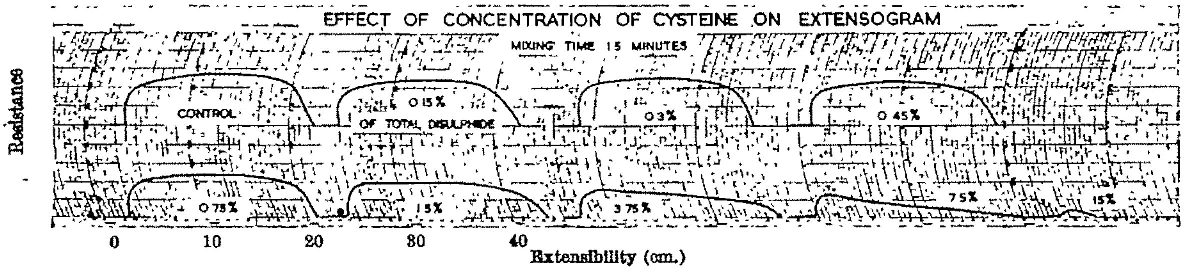

Fig. 5. Extensograms showing the effect of increasing amounts of cysteine. For conditions and disulphide content of flour, see Fig. 2. Percentages given represent μmoles cysteine in relation to μmoles disulphide present in the flour

interchange. However, it can be stated that only small percentage changes in these bring about a marked loss of strength and increased extensibility.

Conclusions

At any given protein content of flour, it appears likely that the rheological properties of dough are directly related to the number of intermolecular disulphide bonds and the rate at which they can interchange with thiol groups. A useful approach to the problem of quality differences in wheats would seem to be, that their related doughs differ with respect to either or both of these properties. In this respect it is likely that both water-soluble proteins and gluten fractions of the flour are involved.

The action of improvers, both thiol-blocking and oxidizing agents, can be related to this concept, namely, strengthening of the dough through inhibition of disulphide exchange reactions. In the case of oxidizing improvers, there is the additional possibility of increase in strength of dough through formation of new intermolecular disulphide bonds. The preference in industry for bromate over iodate as an improver can be related to the slower oxidation of thiol groups by the former, leading to the slow development of a stable structure during the preparation and baking of the dough. The action of reducing agents in destroying the structure of dough can be interpreted both as lowering the number of intermolecular disulphide bonds and/or increasing the rate of their exchange.

In the discussion so far, emphasis has been placed on the quantitative importance of intermolecular disulphide bonds and their rate of exchange in determining the strength of the dough. However, components other than proteins and other types of bonds play a part in determining the total rheological properties. In this connexion it is suggested that hydrogen bonding between the amide groups of the large number of glutamine residues of gliadin[10] play a major part in determining the solubility properties. Intermolecular disulphide bonds could then be regarded as stabilizing the more fluid hydrogen-bonded system.

EXPLORATORY BEHAVIOUR IN THE RAT*

By ROGER G. A. STRETCH
Psychological Laboratory, University of Sheffield†

RECENT studies have shown that a rat, confronted with novel, environmental stimulation, manifests much investigatory activity. This exploratory behaviour reduces the 'newness' of the stimulation, so that as the situation becomes familiar exploration diminishes.

Berlyne[1,2] has been concerned with developing a theory to account for the satiation of curiosity responses in rats. In this he employs Hull's[4] two-factor theory of inhibition. A temporary decline in exploratory behaviour is attributed to accumulation of reactive inhibition, while a more slowly developing, permanent decline is interpreted in terms of the acquisition of a conditioned resting-response, that is, conditioned inhibition. These terms require some explanation. Reactive inhibition may be thought of as a negative drive state akin to avoidance of pain. It is an inhibition produced by response and resembles fatigue; and it is believed to be dissipated during periods of rest. If rest periods are too short to allow for dissipation of reactive inhibition when responses are being elicited continuously, there develops an increasingly strong tendency for the cessation of response. When resting occurs, a quantity of reactive inhibition is dissipated. Dissipation of reactive inhibition during rest constitutes reinforcement, so

† Present address: Department of Parasitology and Entomology, Liverpool School of Tropical Medicine.

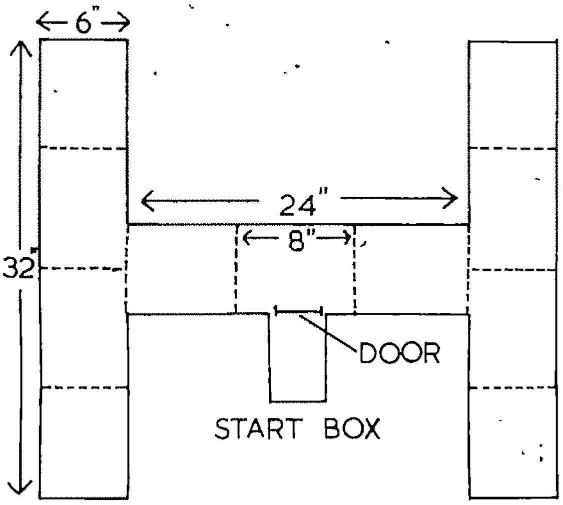

Fig. 1. A plan of the maze used. Exploratory activity was measured by counting the number of 8-in. units an animal entered in each minute. These are shown by the broken lines on the figure

that the response of resting becomes conditioned to whatever stimuli are present in the situation. This acquired tendency to rest is conditioned inhibition.

Thus Berlyne showed[4]: (i) rats enter an alcove in an exploratory box more frequently if it contains a novel object (for example, a wooden cube) than if it is empty; this supports the view that a novel stimulus evokes the curiosity drive; (ii) the amount of curiosity declines rapidly with continuous exposure to a novel object; this decline is interpreted in terms of the accumulation of reactive inhibition, primarily; (iii) there is a relatively permanent decrement in curiosity after initial exposure; rats enter the alcove of an exploratory box to investigate a novel object less frequently as daily trials proceed and this is taken to support Berlyne's application of conditioned inhibition to explain the adaptation of curiosity responses.

While Berlyne found evidence to support this theory, Montgomery[5] did not. Working at Yale University, Montgomery studied exploratory behaviour in simple maze environments. Typically, rats are placed in an *H*-maze, the alleys of which are marked out in 12-in. units. The number of units an animal enters in each minute of a 10-min. trial constitutes a measure of exploratory activity. Rats tend to enter many units initially, whereas few are entered towards the end of a trial. Montgomery also found that if a 10-min. trial is given each day, there is full 'recovery' of maze exploration. Therefore, he concluded that conditioned inhibition was not applicable because he could find no evidence for a permanent decrement in exploratory activity.

Berlyne stated, in reply: "We can only hazard the suggestion that maze runways present a large assortment of novel stimuli, so that a ten-minute exploration period may not allow enough time to satiate the curiosity aroused by most of them to the point at which a permanent decrement occurs" (ref. 2, p. 245). However, he did not test this supposition. Thus, a controversy continues to exist, and an experiment was designed to clarify it.

The apparatus consisted of an enclosed *H*-maze, the main dimensions of which are shown in Fig. 1. The walls of the maze were 6 in. high, and the maze was covered with plate glass. The centre piece of the *H* was painted white and the two arms grey. Each alley was marked off in 8-in. segments. The maze was placed in an arena 5 ft. square, and 4 ft. high. This enclosure was constructed with metal strip, and covered with butter-muslin. Thus, the maze was enclosed in a relatively homogeneous environment. Further, it was illuminated by three red 15-W. lamps suspended above the maze. These afforded a low but even source of illumination. During the maze trials, the room was in darkness, so that the butter-muslin enclosure provided an efficient one-way screen, that is, the observer could watch an animal with little danger of distracting it by his own movements. An animal was placed in the starting box for 1 min. before the door was raised, thus allowing a brief period of adaptation before any trial commenced.

The subjects were 15 male albino rats of 110 days of age. Of these 15 animals, 6 were 'non-reactive', and 9 were 'reactive'. These animals were the offspring of breeding nuclei of the 10th generation of Maudsley Reactive and Non-reactive strains, respectively, which originally formed a part of a selective breeding study of emotionality which is being conducted at the Institute of Psychiatry (Maudsley Hospital), Animal Psychology Laboratory, London[3]. (I am indebted to Dr. P. L. Broadhurst for allowing us to purchase this stock for use in Sheffield.) Unfortunately, it was not possible to submit these animals to the open-field test at the time of this experiment, although this technique[3] was used in later work.

After each animal had been habituated to handling, they were assigned randomly to one of three groups, designated *A*(20), *B*(40) and *C*(60), respectively. There were five rats per group. On day 1, each animal received a 20-min. trial in the maze. On day 2, group *A*(20) received a 20-min. trial, group *B*(40) a 40-min. trial, and group *C*(60), a 60-min. trial. This procedure was repeated on days 3 and 4.

After the appropriate trial on day 4, the animals were returned as usual to their home cages, where they remained, untouched, for 9 days. On the tenth day, each animal was given one 20-min. trial in the maze. Throughout the experiment, all animals were supplied with food and water *ad libitum*, except when in the maze.

The number of maze units entered in each minute of a trial constituted the measure of exploratory activity.

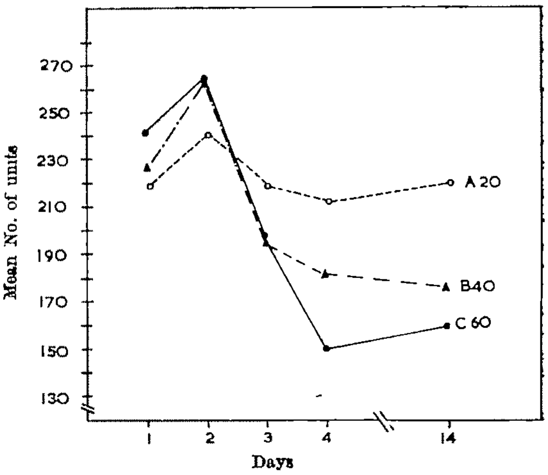

Fig 2. Mean number of maze units entered in the first 20 min. by each of the groups during their daily trials

Four main results emerged from this work. These may be seen from Fig. 2. In the first place, there were no significant differences between the groups in amount of exploration during the 20-min. trial of day 1. Nor were any differences found between the reactive and non-reactive rats on day 1. (The results were analysed by non-parametric techniques.)

Secondly, a comparison of the mean amount of exploration on day 1 with that on day 2 revealed a significant increase for the 15 rats taken as a whole. Further analysis showed that the reactive rats were mainly responsible for this, in that their day 1 to day 2 increase was significant ($P = 0{\cdot}05$), whereas that of the non-reactive animals was not.

Thirdly, differences between the groups failed to reach significance on day 3. However, on day 4, the difference in exploration between groups A(20) and C(60) during the *first* 20 min. was highly significant ($P = 0{\cdot}004$). The difference between groups A(20) and B(40) did not reach an acceptable level.

Lastly, the differences in mean exploration scores after a period of 9 days absence from the maze reveal a decrement for those rats given extended periods of exploration during the first phase of the experiment. The difference between A(20) and B(40) was significant at $P = 0{\cdot}05$ (two-tailed test); the difference between group A(20) and group C(60) was significant at a more acceptable level ($P = 0{\cdot}01$). However, the mean difference between group B(40) and group C(60) was not significant.

The first result, namely, the day 1 to day 2 increase in exploration, has not been reported, previously, by other investigators. However, it has been suggested that novel stimuli may elicit fear as well as curiosity[6], and this effect may be due, therefore, to the extinction of fear responses elicited during the first trial. This view gains support in that emotionally 'reactive' rats manifest this increase more markedly than 'non-reactive' animals. Further research is needed to test this hypothesis.

With regard to a controversy concerning the permanency of a decline in exploratory tendencies after repeated exposure, the results of this experiment lend support to Berlyne's position. They suggest that Montgomery failed to allow rats sufficient time to explore a novel environment to the point at which a more permanent decrement occurs. More research is needed to confirm the adequacy, as opposed to the usefulness, of Berlyne's hypothesis. However, a neurophysiological basis for the inhibitory concepts of this theory may be found in experiments[7] concerning habituation of the arousal response in cats.

I am indebted to Dr. Peter McKellar for supervision and help in conducting a series of experiments of which the present experiment is a part.

THE AFFINITIES OF THE NEW OLDUVAI AUSTRALOPITHECINE

DR. L. S. B. LEAKEY recently reported in *Nature*[1] the discovery of an essentially complete hominid skull without mandible from site *FLK* at Olduvai Gorge. He regards the specimen as an australopithecine that differs more from either of the two known genera, *Australopithecus* and *Paranthropus*, than these two differ from each other. He therefore erected the genus *Zinjanthropus* to accommodate the new specimen.

The description consists largely of a list of twenty 'major' differences between the new specimen and the two previously known genera. Some of these points cannot be dealt with as they are briefly stated in terms which are not useful by themselves for comparison. Others, for example, continuous nuchal crest, enlargement of the mastoid area, prominent temporal lines, large areas for masseter attachment, etc., do not each represent a separate difference; all are reflexions of the fact that this specimen is a little larger and more muscular than the known South African specimens of *Paranthropus*. In at least one case (nuchal crest) comparison with the latter specimens is not possible since there is no known male specimen with the relevant area preserved. The remainder are not real differences and will be dealt with briefly:

(1) The inion is lower relative to the Frankfort plane: In both *Australopithecus* and *Paranthropus* the base of the external occipital protuberance is almost exactly in the Frankfort plane, as seems to be the case with the Olduvai specimen.

(2) The posterior wall of the occipital bone rises more steeply to form, with the parietals, a very high-vaulted posterior region of the skull: This is also the case in *Paranthropus*, less so in *Australopithecus*. *Paranthropus* has an almost spheroidal brain-case which is relatively low and narrow anteriorly but steep-sided and higher posteriorly. *Australopithecus* has a brain-case more nearly like that of a dolichocephalic modern hominine. The Olduvai specimen has the *Paranthropus* type of brain-case.

(3) The form of the tympanic plate is different: Dr. Leakey demonstrated this point to me on the specimen to make clear his meaning. This feature is variable in *Paranthropus* and includes an instance of close resemblance to the Olduvai specimen. The observed range of variation is illustrated in Fig. 1. Being thus variable, it is in any event a feature of low phyletic valence.

(4) The very unusual position of the nasion—almost coinciding with glabella: This is true of *Paranthropus* and in at least some cases of *Australopithecus* also. In *Paranthropus*, as in the Olduvai specimen, the nasals are relatively very wide near the nasion.

(5) The very great absolute and also relative width of the inter-orbital area. The proportionate width of the inter-orbital area to that between the external orbital angles is 26·6 in the Olduvai specimen; 26·2 (*SK* 846), 25·3 (*SK* 48) in two specimens of *Paranthropus*. A single specimen of *Australopithecus* gave a value of 24·1, while a random sample of eight

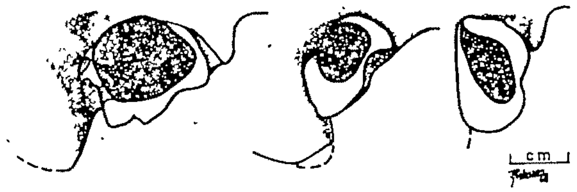

Fig. 1. Variation of the tympanic bone at the lateral end of the external auditory meatus in *Paranthropus* from Swartkrans (*SK* 48, *SK* 52 and *SK* 848). The Olduvai specimen resembles in this feature the condition illustrated in the middle diagram

modern human skulls gave a range of 23·4–30·5. No taxonomic significance can therefore be attached to this point on the present evidence.

(6) The very deep palate which is even more markedly like that of *Homo* than *Australopithecus*, and is quite unlike the form seen in *Paranthropus* : In *Homo*, the degree of vaulting of the hard palate is variable, but the difference in depth at the incisive fossa and the back of the palate is normally relatively slight. This is true also of *Australopithecus*. The palate of *Paranthropus* differs in that it slopes more markedly ; that is, there is always an appreciable difference between the anterior and posterior depths —in some cases there is no depth at all anteriorly, in others the anterior depth is appreciable. The Olduvai specimen shares this characteristic of relatively much greater posterior compared to anterior depth, reflecting the *Paranthropus* condition, not that of *Homo* and *Australopithecus*.

(7) The shape and arrangement of the zygomatic process of the maxilla : The Olduvai specimen has a relatively poorly developed zygomatic process, the lower border of which passes almost horizontally from the zygo-maxillary suture to the main body of the maxilla. In some specimens of *Paranthropus* the process passes from the zygo-maxillary suture downward and medial-ward at a fairly sharp angle like an inverted flying buttress. However, *SK* 52, of the same dental age as the Olduvai specimen, has a trace only of the buttress and *SK* 846 (mature adult) has no trace of it, as in the Olduvai specimen.

(8) The relatively greater reduction of the canines in comparison with the molar-premolar series than is seen even in *Paranthropus* : As the marked change of proportion between anterior and cheek teeth occurs in *Paranthropus* and the Olduvai specimen between canine and P^3, the degree of reduction can be measured by the ratio between the modules of these two teeth. The ratio for the Olduvai specimen is 64·9 while that for three specimens of *Paranthropus* ranges from 61·8 to 78·8.

(9) In the species diagnosis Leakey refers to the presence of a sagittal crest "at least posteriorly". The reason for this statement is not clear, since the crest occupies a position identical to that in *Paranthropus*—on roughly the middle third of the distance between glabella and inion. In neither form is the sagittal crest known to reach as far back as the planum occipitale or even the posterior part of the sagittal suture.

It seems to me that the most fruitful approach to an understanding of the australopithecine skull, within the framework of hominid structure, is in terms of diet and the nature of the dentition. *Australopithecus*, as an omnivore eating at least a moderate amount of flesh, has a dental apparatus very similar to that of the older hominines. The relative sizes of the teeth along the tooth row are closely similar, as is the arrangement of the dental arcades. The anterior teeth, especially the canines, are well developed, but the post-canine ones only moderately so. The skulls are also similarly constructed except for the relatively small cranium, compared to the face, of *Australopithecus*.

In *Paranthropus* the situation is very different. Here the anterior teeth, set in an almost straight line across the front of the palate, are appreciably reduced in size compared to those of *Australopithecus*, while the post-canine teeth are appreciably larger. This difference in arrangement and proportion is very striking and is characterized by the very small canine tooth set firmly against a massive premolar. All this must clearly have functional meaning. The massive crushing and grinding teeth, the relatively unimportant anterior teeth and frequent damage to the enamel which could only have been caused by small, very hard particles (presumably grit), and the large size of the animal suggest a predominantly vegetarian diet. Concentration of heavy dental function in the post-canine region has strongly modified the skull architecture. The massive cheek teeth, especially the molars, have strongly developed root systems and hence are set in heavy bone, and the back of the palate is relatively deep. Owing to the heavy chewing forces, the palate is thick, the jaws are massive, especially where supporting the cheek teeth, the zygomatic arches are strongly built, the circum-orbital bone is strong in the stressed areas, the strongly stressed pillars on either side of the pyriform aperture are thick and the medial and lateral pterygoid plates, especially the latter, are large and strong. However, the large dental battery requires heavy musculature to operate it—hence further changes from the *Australopithecus* and hominine pattern. The areas of origin and insertion of these muscles are sturdy ; hence the large surface area of the mandibular ramus, the massive zygomatic arch—which also is widely spaced from the brain-case to allow for the very large temporal muscle—large medial and lateral pterygoid plates, clearly defined temporal lines, sagittal crest and apparent prominence of the supraorbital tori. The large muscles associated with the large and chunky animal result in well-defined muscular ridges on the occiput and the prominence of the mastoid area—assisted by the large temporal muscles which necessitate appreciable lateral extension of the zygomatic arch. It is probable also that the large temporal muscles have influenced the shape of the brain-case anteriorly to help produce the low and narrow shape characteristic of *Paranthropus*. As is usual in relatively massive skulls where large surface area is necessary, some reduction of weight has occurred by increased pneumatism. The mastoid region (not the mastoid process alone) is strongly cellular and the air spaces in the skull base, the maxillæ and the frontal bone are all very large.

The curious and characteristic features of the *Paranthropus* skull, which parallel some of those of the gorilla skull and mark it off so clearly from that of *Australopithecus*, are all functionally related and determined largely by the specialized diet of this creature as compared to all other known hominids. These functional and structural differences indicate clear adaptational differences between the two forms and hence also differences of evolutionary direction. In modern systematics, adaptational differences of this order and nature are normally accorded generic rank.

The features of the Olduvai specimen fit the *Paranthropus* pattern as here outlined very accurately—

the differences being almost entirely of the sort shown to be variable within a single population by the sample of nearly 200 specimens of *Paranthropus* now in the collections of the Transvaal Museum. The chief feature of the Olduvai form which does not fall within the observed range of variation of this collection is size. The best size comparison is with the only male specimen with good teeth which has P^3–M^1 preserved in sequence and is of the same dental age as the Olduvai specimen. The latter is only 8·4 per cent larger. The average percentage difference for five skull and dental series dimensions compared to those of a fully adult female skull is 17·4 per cent. As Schultz has shown in a number of papers, intra-specific variation in measurable primate anatomical characters can often greatly exceed the above values.

The validity of separate specific status is not clear on the basis of the single specimen, and it is perhaps wisest to leave it as distinct. In the light of the above analysis, however, separate generic status seems unwarranted and biologically unmeaningful. I therefore propose that the name of the Olduvai form be *Paranthropus boisei* (Leakey).

J. T. Robinson

Transvaal Museum,
Pretoria.

---

[1] *Nature*, 184, 491 (1959).

The exact taxonomic label that should be applied to the skull that I have named *Zinjanthropus*, from Olduvai, and which I described in *Nature* of August 15, 1959, seems to me relatively unimportant at the moment. Inevitably, different scientific workers have different ideas of what characters justify specific, generic, and even superfamilial rank. After all, this is purely a question of artificial labels.

Dr. Robinson and I agree that *Zinjanthropus boisei* is closely related to the Australopithecinae; we agree that it has certain resemblances to *Paranthropus*, and we disagree mainly in that he believes the differences to be insufficient to justify separate generic rank, while I think they do.

It is hard enough to reach agreement among zoologists on the taxonomic status of living primates, under conditions in which we possess the skull, skeleton, skin and viscera for study, and it will always be much more difficult to do so when we have only fossils to guide us. I can only say that the very considerable additional work that I have done on the *Zinjanthropus* skull since my preliminary report in *Nature* has greatly strengthened my view that it is entirely different from *Australopithecus* and *Paranthropus*, differing from both these genera more than they do from each other.

I do not feel that any useful purpose would be served by entering into a long discussion with Dr. Robinson in *Nature* at present, since the more detailed study of the Olduvai skull which is now in hand will not, I hope, be too long delayed. However, Dr. Robinson makes certain statements which may mislead those who read them, unless I comment on them. I will therefore do so as briefly as possible.

First of all, whereas in *Paranthropus* and *Australopithecus* (as Dr. Robinson says) the external occipital protuberance lies more or less on the Frankfort plane, in *Zinjanthropus* it lies below it.

Robinson's description of the brain case of *Paranthropus* as "almost spheroidal", but also "relatively low and narrow anteriorly but steep-sided and higher posteriorly", does not seem to make sense, for the two statements seem to cancel each other out. In any event, such a combined description does not fit the brain case of *Zinjanthropus*.

Robinson illustrates the range of the tympanic plate (see in profile), in *Paranthropus*. None of these three illustrations closely resembles the tympanic plate of *Zinjanthropus*, although the one to the left appears to be rather closer than the middle one.

Without knowing the points at which Robinson measures inter-orbital width and external orbital width, I cannot comment upon his comparisons of his *Paranthropus* figures with mine for *Zinjanthropus*.

As to the morphology of the palate, I do not know upon what evidence Robinson is basing his statement, since I have published no measurements of the palatal depth in *Zinjanthropus*. I must repeat, however, quite categorically, that the morphology of the *Zinjanthropus* palate in no way resembles that of *Paranthropus*.

I cannot accept Robinson's statement that the zygomatic process of the maxilla in *Zinjanthropus* is "relatively poorly developed"; I would say rather, as I have said before, that it is developed in an entirely different morphological manner from *Paranthropus*.

As regards the position of the sagittal crest, in *Zinjanthropus* it ceases to be a crest and divides into two temporal lines well behind the line drawn vertically through the ear when the skull is on the Frankfort plane. In *Paranthropus* (in all the published photographs), the sagittal crest extends a long way forward of such a vertical line through the ear when the skull is on the Frankfort plane, and it is therefore wrong to say, as Robinson does, that "the crest occupies a position identical to that in *Paranthropus*".

Finally, I do not understand the significance of a comparison of "the ratio between the modules of these two teeth", that is, the canine and P^3. Robinson has defined a module as the sum of the length and breadth of a tooth divided by two, and I am at a complete loss to understand how the ratios of modules can have any significance. It must be obvious that one can have on one hand a canine tooth 16 mm. long and 6 mm. wide (module equals 11), and a premolar 9 mm. long and 7 mm. wide (module equals 8), while in another specimen one could have a canine which measured 11 mm. × 11 mm., and a premolar which was only 5 mm. long and 11 mm. wide, yet the ratio of the modules in the two sets of teeth would be identical, but completely without significance.

In any event, the ratio between the canine and the premolar alone cannot have any bearing upon the relation of the canine size to the total molar–premolar series, unless the premolar bears a constant relation to the total post canine series.

I therefore repeat my statement that in *Zinjanthropus* there is a relatively greater reduction of the canines in comparison with the total molar–premolar series than is seen in *Paranthropus*, and maintain that Robinson has in no way disproved this statement.

I agree with Robinson that we need to study the *Australopithecus* skull structure and dentition in terms of diet and mode of life, and I shall certainly do so as far as *Zinjanthropus* is concerned in my fuller report.

LETTERS TO THE EDITORS

PHYSICS

Comparison of the Charges of the Electron, Proton and Neutron

We have noted the communication from Bondi and Lyttleton[1] criticizing our experiment[2] and we would like to clarify the alleged obscurities.

Bondi and Lyttleton suggest that a supply of electric charges may be detached from the walls of the nozzle, and that if the gas is not electrically neutral it will attract these charges into the gas until it is neutralized. For this mechanism to work two conditions must be satisfied. First, it is necessary to find a process for the production of free charges, and secondly, a process which arranges that the charge carried away by the gas is controlled by the space-charge field, so that charge is carried away just until the space charge has been neutralized. We examine these two conditions in turn.

(1) The observed probable upper limit of the space-charge of the emerging gas was 3×10^{-14} coulomb on 81 litres, or $3 \cdot 6 \times 10^{-13}$ coulomb/m.^{3}. Consider whether a gas with five times this space-charge density (that is, $1 \cdot 8 \times 10^{-12}$ coulomb/m.^{3}) could produce neutralizing charges. Such a space-charge would produce a field intensity, E_s, of 5×10^{-4} V./m. at the surface of the tube, which is too small by a factor of 10^9 to produce field emission of electrons and too small by a larger factor for the production of ions. Surface ionization, the capture of an electron from an impingeing atom, resulting in a surface charge can occur when it is energetically possible. In the present case, the ionization potentials of argon and nitrogen are 15·6 and 14·5 volts respectively, whereas the work function of brass is only about one-third of these values. Proportional counters have been operated successfully with a continuous flow of gas and with fields at the walls many orders of magnitude greater than E_s, indicating that the flow causes no production of ions. Presumably dust or water drops would have to be present in the gas in order to liberate charges from the walls, which is not the case in our experiment.

(2) We now consider the motion of charges supposed to be released at the wall surface. The field due to the space-charge is far from "amply sufficient to drag along charges", for in addition to the field E_s acting on the charge there is a field due to the image charge in the conductor attracting the free charge back, and this exceeds E_s within 1·0 mm. of the wall (or more than a third of the cross-sectional area). Also there are contact potential differences of the order of 10 mV. between different points of the brass surface, giving field intensities of ~ 1 V./m. Even in the latter field, ions or electrons would move much faster by thermal diffusion than their average motion along the lines of force. Hence the motion of any ions or electrons liberated from the surface by friction would be determined mainly by random diffusion (modified by turbulence), to a lesser extent by the irregular surface fields, with the space-charge fields a few thousand times weaker still. Equilibrium ion and electron densities must therefore be determined mainly by the rates of production and of diffusion loss, and in any event not by making the field component due to space-charge equal to zero. It is, in fact, precisely because the motion of the charges is governed by diffusion that objects can become charged by frictional effects. In these cases the charges are moved in opposition to fields many orders of magnitude greater than those under discussion here.

The remaining points referred to by Bondi and Lyttleton appear to arise from a misunderstanding of the experimental method. They state that it is not clear what happens to the free charges collected by the ion trap. Even if the fate of these ions were really obscure, which it is not, it is clear that the charges do not leave the box *A* which contains the battery. They cannot therefore influence the potential difference between boxes *A* and *B*. Bondi and Lyttleton also state that a "potential of the same order as would be expected in the absence of balancing electrons is actually applied to the very box the potential of which it is wished to measure". The potential applied was in fact considerably larger than the potential measured, but the measurements made are of changes of potential. No one has ever suggested that the potentials of thousands of volts applied to the collectors of ion chambers make the small changes due to the collection of ions inherently more difficult to detect.

Bondi and Lyttleton also have difficulty in finding the "meaning of the large ionization current in the air, the fluctuations of the measured current, and the sudden changes of potential". The ionization in the air around box *A* was due to natural radioactivity and cosmic rays. There is a partial separation of charges by the contact potential differences between the different metals used in the construction, resulting in a current if a suitable compensating potential is not applied. The changes of potential involved in an experimental run (~ 10^{-4} V. at the input of the feedback vibrating reed electrometer) did not change the ionization current significantly. The fluctuations in background current were at least mainly due to ions carried by air eddies (normally one sign of ion is in excess). The sudden jumps of potential occurred when the pressure was changed in the slightly flexible outlet tubes to start the gas flowing: the facts that this caused a small movement and that a small movement caused potential changes were verified. In any event the jumps were independent of the amount of gas released.

Bondi and Lyttleton refer to the "minute difference of charge concerned". In the context of the experiment, this may be misleading. The postulated charge difference is equivalent to about 100 electronic charges per c.c. This is much larger than the charge density in an ion chamber under normal conditions, and about the same as the number of ions in air at sea-level. By commonly accepted standards, the charge involved in our experiment is quite large, but the fields are very small.

In addition to the comments of Bondi and Lyttleton, it has been pointed out to us by J. Leverett

Davis that it is possible to make a plausible extrapolation of our measured points which leads to an upper limit for the charge which is nearly twice the value quoted in our communication, but still too small to remove the conflict with the hypothesis of Bondi and Lyttleton.

We do not wish to imply that our experiment is infallible, but we believe that if a loophole exists it is one that has not yet been mentioned. Nevertheless, we consider that a hypothesis as important as that suggested by Bondi and Lyttleton cannot be dismissed by one experiment, or two of a similar type, and feel that it is highly desirable that other experiments should be made which do not depend on flowing gases.

Profile of Upper-Atmosphere Air Density at the Height 180–212 km. derived from the Orbit of *Sputnik* III

The resistance of the air to a moving object like a satellite causes a steady decrease of the semi-major axis and eccentricity of the orbit. The motion of the satellite grows faster and the satellite itself submerges deeper and deeper into the atmosphere at every revolution. When the satellite has descended to a certain level, where the heating from impact of air molecules on the frontal surface becomes great enough, the satellite burns out. For the purposes of ephemerides and for the prediction of the lifetime of the satellite, it is necessary to know how its orbital elements will be changed by the resistance of the air—supposing that we have some knowledge of the density of the air at the height where the satellite is moving, and of the drag coefficient of the satellite. Unfortunately, these data are not usually known with sufficient accuracy. But we can reverse this problem and search for a solution of how the air density could be determined from observed changes in size and shape of the orbit when the drag coefficient of the satellite is known. If we do not know this drag coefficient (which depends on the size, shape and mass of the satellite), we can still determine at least the gradient of the air-density. G. V. Groves published two valuable papers[1,2] last year, in which very accurate methods for such a determination have been developed. The only assumption made here, which could be accepted as a general approximation, is that air-density varies with height according to the relation:

$$\ln \frac{\rho}{\rho_{00}} = -\frac{1}{H_1}(h - h_{00}) + \frac{1}{H_2^2}(h - h_{00})^2 \quad (1)$$

where ρ_{00} is the density of the air at the height h_{00}, H_1 is the scale-height in the case of an isothermal atmosphere, and H_2 enables us to take account of the variation of atmospheric temperature with height. From the data of six different satellites with perigees between 180 and 650 km., Groves has found that, for $h_{00} = 200$ km.:

$$\rho_{00} = 3{\cdot}8 \times 10^{-13} \times (1 \pm 0{\cdot}1) \text{ gm./cm.}^{-3}$$
$$H_1 = 46 \pm 5 \text{ km.}$$
$$1/H_2^2 = (0{\cdot}028 \pm 0{\cdot}013)/46^2$$

In the second paper, methods have been developed for the determination of H_1 and H_2 without any knowledge of the drag coefficient. In this case, of course, the determination of ρ is not possible.

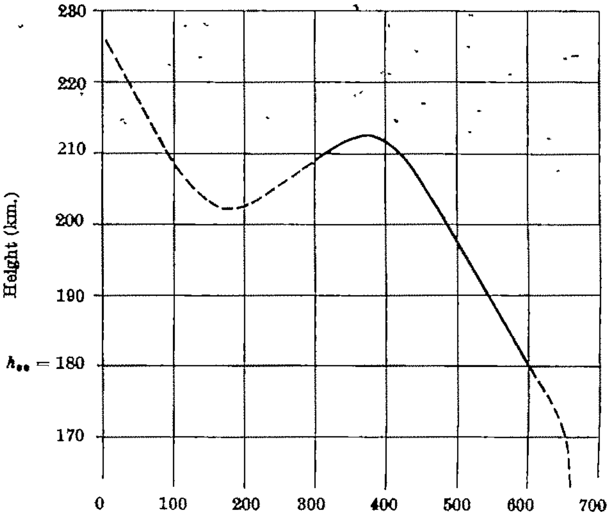

Fig. 1

At the time when these papers were published, only a few not very accurate data of the orbits were available. Meanwhile, the third Soviet satellite, 1958δ2, was launched on May 15, 1958, and a great number of observations with improved instrumentation have provided accurate orbital elements and their changes. I have analysed all the data available so far. Nearly 100 sets of orbital elements have been taken into consideration. Not all have the same weight; it seems that the accuracy was improved after March 1959. For this reason I have restricted the analysis

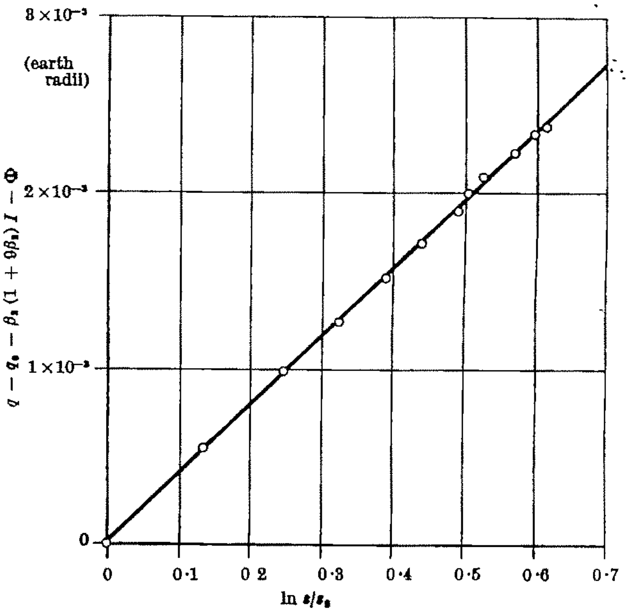

Fig. 2

in the present communication to the time interval between March 11, 1959, and January 5, 1960, that is, between 300 and 600 days after launching.

During this time-interval: (1) the perigee radial distance decreased from 1·03091 to 1·02824. The dependence of perigee radial distance q on time t could be approximated by the equation:

$$q = 1{\cdot}02137 + 0{\cdot}003713 \log (671 - t) \qquad (2)$$

with a standard deviation ± 0·9 km.; (2) the eccentricity decreased from 0·08215 to 0·04191 in the same time-interval; (3) the perigee height changed in a more complicated manner, as shown graphically on Fig. 1; first, it rose from 208·7 km. to its second maximum of 212·2 km. at $t = 370$ days; after that date it was steadily decreasing and at the end of the time interval, $t = 600$ days, it was only 180·1 km.

These changes in the perigee height were produced by the motion of the angular perigee distance ω, which brought the perigee point above various latitudes of the Earth. The height-interval of 31·1 km. seems to be great enough to enable the determination of both constants H_1 and H_2. We used for this purpose smoothed orbital elements at twelve points where the perigee height was on the rising branch 210, 211 and 212 km., and then on the descending branch 212, 211, 210, 205, 200, 195, 190, 185 and 180 km. The computation was carried out according to the equation:

$$q - q_0 = \tfrac{1}{2}H_1(1 + 3\beta_2) \ln \frac{s}{s_0} + \beta_2 (1 + 9\beta_2) I + \Phi \qquad (3)$$

where $\beta_2 = H_1^2/H_2^2$ and $s = qe/(1 + e)$. The integrals I and Φ depend on orbital elements and their changes with time and also on β_2. For details, one must refer to the original paper[2].

The result of my analysis is shown in Fig. 2, where $q - q_0 - \beta_2(1 + 9\beta_2)I - \Phi$ is plotted against $\ln s/s_0$. The straight line fitted to the twelve computed points by the method of least squares is in satisfactory agreement with equation 3, the mean error being only $\pm 2{\cdot}0 \times 10^{-5}$ earth radii ($= \pm 0{\cdot}13$ km.). The gradient of the line, $\tfrac{1}{2}H_1(1 + 3\beta_2)$, is equal to $\pm 388{\cdot}73 \times 10^{-5}$. With this value equation 3 has been recomputed to determine β_2; thus:

$$\beta_2 = 0{\cdot}024 \pm 0{\cdot}006$$

With this value, equation 3 has been used for the determination of H_1, and I have found:

$$H_1 = 46{\cdot}3 \pm 0{\cdot}7 \text{ km.}$$

As shown by the small probable errors, both values β_2 and H_1 are reliably determined. They agree well with the values obtained by G. V. Groves[1]. The scale-height is again 2–3 times greater than that derived from various theoretical models of the upper atmosphere. It is also noticeable that no seasonal effect was detectable during 300 days covered by this analysis, although during the same time the other artificial satellites with higher perigees were strongly influenced by changes of air density of long duration.

RADIOPHYSICS

The Mesopause Region of the Ionosphere

In a recent communication, Gregory[1] suggested that the presence of free electrons at heights in the atmosphere between 80 and 90 km. may be due to the photo-ionization of dust which accumulates at the mesopause. Rocket measurements[2] have shown that the electron density at this height is about 1,000 el./c.c. on a normal day. This is also the order of magnitude of electron density required to account for the absorption of radio waves in the D region. It is of interest to see whether photo-ionization of the dust is able to give this observed electron density.

Noctilucent clouds are observed at the mesopause. While their composition is uncertain we arrive at an upper limit to the density of dust by assuming the clouds are composed of dust particles. From the luminosity and colour of the clouds Ludlam[3] estimated the particle density to be 0·01–1 particle per c.c. and the radius to be 1000 Å.–100 Å., the lower density corresponding to the larger radius.

Now the shortest wave-length of appreciable intensity of ultra-violet radiation from the Sun falling on the dust particles is about 2000 Å., except for the Lyman-alpha line (λ1216 Å.). The total Lyman-alpha flux[4] would only produce about 3×10^{-6} electron per c.c. per second by photo-ionization of the dust particles, whereas a rate of production of at least 0·06 electron per c.c. per second is required to give the observed electron density in this region[5]. Thus the Lyman-alpha photons can play no significant part in this process. A similar argument applies to short X-ray radiation.

The wave-length of 2000 Å. corresponds to a photon energy of about 6 electron-volts. The threshold energy for photo-electric ejection is about 3 electron-volts, so that the potential of the dust particles cannot exceed 3 volts. This potential determines the maximum positive charge on the particles and hence the maximum electron density. This turns out to be 2 el./c.c. for $r = 1000$ Å. and 20 el./c.c. for $r = 100$ Å., at least 50 times too small.

If the number density of particles is allowed to increase 50 times (for $r = 100$ Å.) to give the required electron density, a further difficulty arises. When an electron collides with a positively charged dust particle, there is an 80 per cent chance that the electron would be absorbed, so that the free electrons would disappear with a time constant of about 8 sec. Gregory, however, observes that the layer at 80 km. persists all night.

While it seems probable that the layer is associated with the mesopause, the suggestion that it is formed by photo-ionization of the dust particles appears to be untenable.

Apparent Radio Radiation at 11-m. Wave-Length from Venus

In 1956 several preliminary communications reported the apparent reception of 11-m. radiation from the planet Venus[1]. In particular, one communication reported coherent or quasi-coherent radiation, designated Class II, which was also thought to originate from Venus. From further observations and subsequent analyses it now appears definite that these signals were not from Venus but were in all cases almost certainly interference of terrestrial origin.

Regarding the reports of the noise-type of radiation, designated Class I, a careful re-examination of the results indicates that the evidence is not sufficient to be sure that such radiation from Venus was observed. Attempts by others to detect the radiation have also been unsuccessful[2]. The validity of any deductions based on these observations, such as the rotation period of the planet, is, therefore, extremely doubtful.

Although some records, such as the one in Fig. 11 of a later article[3], show interferometer patterns which could be due to radiation from Venus, they are not conclusive. However, the fact that these records do suggest 11-m. radiation from Venus makes it difficult to rule out the possibility of such radiation completely. To determine the existence or non-existence of such radiation beyond any doubt, further observations are needed using a radio telescope of much higher resolution and better stability than was available in 1956.

An Estimate of the Peak Sunspot Number in 1968

The smoothed peak sunspot number during the current cycle of solar activity attained a value in 1958 which has not been exceeded since accurate observations were begun more than 200 years ago. Conditions in the atmosphere of the Sun near the epoch of peak activity, and the closely related changes in the ionosphere, have already been the subject of comment[1].

It has been suggested that the uninterrupted rise in successive peak sunspot numbers since 1928, and its culmination in the unprecedented high peak of 1958, may indicate that the Sun is undergoing a long-term change and that the next peak, which will probably occur in about 1968, will be even higher than that of 1958. The opposing view is that, since the peaks of 1948 and 1958 were very high, the 1968 peak will be a very low one. These possibilities are of more than academic or scientific interest; they have a bearing on the effectiveness of the world-wide network of high-frequency radio-communication links, the successful operation of which depends on the reflexion of radio waves from the ionosphere. The operating conditions on such radio links are profoundly modified by changes in solar activity, and Hitchcock[2] has pointed out that, with the present-day overcrowding of the high-frequency radio spectrum, the occurrence of a solar cycle which attained only a low peak might lead to unforeseen difficulties.

It is of some importance, therefore, to estimate the probable limits within which the forthcoming peak sunspot number will lie. Obviously it is impossible to make a precise estimate; the present objective is merely to examine the purely statistical evidence contained in the sequence of twenty peak values which have occurred since 1750 and to decide whether there are any grounds for believing that the next peak will be either very high or very low. The cycle-matching technique described by Herrinck[3] has not been used because it cannot be safely extended beyond the end of the present cycle[4].

From a study of the lengths of sequences of uninterrupted increases and decreases in the peaks for successive cycles, it is possible to estimate the probability of occurrence of a sequence of three increases such as that which took place between the peaks of 1928 and 1958. The conclusion reached is that such an event is not an improbable one ($P \simeq 0{\cdot}12$), and it follows that its occurrence ought not to be interpreted as an indication of a long-term upward trend in solar activity. It is estimated on similar grounds that the probability of a fourth increase, leading to an even higher peak in 1968 than in 1958, is approximately 0·3.

The range of values within which the next peak will lie can be estimated from the frequency distributions of either the magnitudes of the twenty observed peaks or the differences between successive peaks. From such evidence it is found that there is a high probability that the 1968 peak will be between 110 and 160. The autocorrelation function for the twenty peaks (R) since 1750 has been evaluated, but the correlation coefficients differ significantly from zero only for R_n, R_{n+1} and R_n, R_{n+2}. The regression lines for these two cases have been used to forecast the peak in 1968; and the values obtained, with their standard errors of estimate, are 154 ± 38 and 97 ± 36 respectively. These values are consistent with the range of values (110–160) based on the frequency distributions referred to earlier.

The various independent estimates of the next peak have been combined, taking into account their respective probabilities and making an allowance for the fact that the estimates are based on a sample of only twenty values. It is concluded that there is a probability of at least 0·75 that the next smoothed peak sunspot number, which will occur about 1968, will be in the range 110–160. Thus it seems reasonable to expect that ionospheric and radio-communication conditions during the 1964–74 solar cycle will be roughly comparable with those which occurred during the 1934–44 and 1944–54 cycles.

This communication is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research; the work will be described more fully elsewhere.

METEOROLOGY

Wind Profile in Thermally Stratified Flow

THE variation of horizontal wind-speed u with height z in the air flowing over uniform ground is, in conditions of neutral equilibrium, well represented by the expression:

$$\frac{\partial u}{\partial z} = \frac{u^*}{kz} \qquad (1)$$

where u^* is the 'friction velocity', defined as $u^{*2} = \tau/\rho$, τ being the horizontal shearing stress caused by the wind and ρ the air density. k is von Kármán's universal dimensionless constant. This relationship, well based theoretically and amply verified by experiment (see, for example, Sheppard[1]), is expected to apply at all heights within the layer of constant shearing stress.

Attempts to extend this formulation to the case of thermally stratified flow have, however, met with severe difficulties, and up to the present time such treatments as have been given, mainly of a quasi-theoretical or frankly empirical nature, have met with only partial success and this limited to small departures from the neutral state.

It will be shown here that it is possible to derive a formal solution to the problem devoid of all arbitrary constants, expressing the variation of wind with height uniquely in terms of the shearing stress and the vertical heat flux H associated with the thermal stratification. No restriction is imposed on the magnitude of these latter quantities, and the result is applicable at all heights within which τ and H remain constant.

In a steady state of turbulence, the rate of viscous dissipation of turbulent kinetic energy at a given point, ε per unit volume of air, is represented by:

$$\varepsilon = \tau \frac{\partial u}{\partial z} + \frac{gH}{c_p T} \qquad (2)$$

g is the acceleration of gravity, c_p the specific heat of air at constant pressure and T the temperature of the air. The terms on the right-hand side of (2) are, respectively, the rate of working of the shearing stress on the mean rate of strain, and the work done per unit time against gravity by buoyancy.

I now introduce a new height variable X, defined according to the equation:

$$\tau \frac{\partial u}{\partial X} = \tau \frac{\partial u}{\partial z} + \frac{gH}{c_p T} \qquad (3)$$

X, which will be seen intuitively to be a function of z, τ and H, thus permitting the combination of contributions from both sources of energy in the pseudo-shearing stress term $\tau\, \partial u/\partial X$.

A similarity assumption is now made that:

$$\frac{\partial u}{\partial X} = \frac{u^*}{kX} \qquad (4)$$

The hypothesis here is that, just as in (3), the new height X is able to accommodate in the one term the energy supply both from the mean motion and from buoyancy, so in (4) it will preserve, in conditions of thermal stratification, the linear inverse relationship between wind shear and height characteristic of simple shear flow. It must be emphasized that, at this stage, (4) is no more than a reasonable assumption the validity of which remains to be assessed by the accuracy of its consequences now to be derived.

Elimination of u between equations (3) and (4) leads to the differential equation:

$$1 = \frac{dX}{dz} - \frac{X}{L} \qquad (5)$$

where L, of dimension length, has been introduced to represent $-\dfrac{c_p \rho T u^{*3}}{kgH}$. (The notation here follows that of Monin and Obukhov[2].)

Integration of (5), invoking the condition that as $L \rightarrow \infty$, $X \rightarrow z$, yields:

$$X = L\,\{\exp(z/L) - 1\} \qquad (6)$$

from which, after a little manipulation,

$$\partial u/\partial z = u^*/kL\,\{1 - \exp(-z/L)\}^{-1} \qquad (7)$$

A recent attempt, by Monin and Obukhov (*loc. cit.*), to solve the problem now under discussion proceeds by dimensional arguments to postulate that:

$$\frac{\partial u}{\partial z} = \frac{u^*}{kz}\left\{1 + \alpha_1\left(\frac{z}{L}\right) + \alpha_2\left(\frac{z}{L}\right)^2 + \ldots\right\}$$

where the coefficients remain to be determined by experiment. The present formulation lends support to this hypothesis, as expansion of the exponential term in (7) shows. Furthermore, it follows from (7) that:

$$1 + \alpha_1\left(\frac{z}{L}\right) + \alpha_2\left(\frac{z}{L}\right)^2 + \ldots = \frac{z}{L}\left\{1 - \exp(-z/L)\right\}^{-1}$$

Integration of (7) between the levels z_1 and z_2 gives:

$$u_2 - u_1 = \frac{u^*}{k}\ln\left[\frac{1 - \exp(z_2/L)}{1 - \exp(z_1/L)}\right] \qquad (8)$$

A similar relation applies to levels z_3 and z_4, whence division eliminates u^*/k to yield:

$$\frac{u_2 - u_1}{u_4 - u_3} = \ln\left[\frac{1 - \exp(z_2/L)}{1 - \exp(z_1/L)}\right] \Big/ \ln\left[\frac{1 - \exp(z_4/L)}{1 - \exp(z_3/L)}\right] \qquad (9)$$

By numerical, or preferably graphical, interpolation equation (9) then permits the determination of L from observed winds, whence substitution of the appropriate L in equation (8) yields u^*. H, the heat flux, can then be determined from the defining expression for L.

The extensive wind observations of Monin and Obukhov (*loc. cit.*) have been analysed within the framework of the present analysis, and yield remarkably consistent values of L and u^* over the whole height-range of 0·5–15 metres, and over a wide range of stabilities. The relevant values of z/L vary from $-7{\cdot}5$ to $3{\cdot}75$. Furthermore, u^* so determined accords almost exactly with its value calculated in an entirely different manner (involving the use of drag coefficient at the lowest level of wind measurement where the analysis shows the effects of buoyancy to be negligible). Equation (8) yields an explicit formulation for the 'roughness length', determinations from which show excellent agreement. In brief, it may be said that the present indications are that the law of wind variation contained in equation (8) promises to be capable of universal application without restriction as regards stability, and at all heights within the layer of constant heat flux and shearing stress.

Analysis of other observational material is now in hand, and an experimental programme in progress designed to assess the validity of the present treatment by comparison of its predictions against values of the shearing stress and heat flux determined directly by the eddy-correlation method.

A full account of the work summarized here, together with that now being undertaken, will be published elsewhere in due course.

GEOLOGY

Uraninite and Thorianite

WASSERSTEIN[1] suggested that the generation by radioactive decay of Pb^{4+} of smaller ionic radii within the crystal lattice of uraninite caused a shrinkage in the unit cell proportionate to the geological age and the shrinkage was of the order of 0 0025–0·0041 Å. per hundred million years. The anomaly in the relation of cell dimensions of Bisundni and Gaya uraninites with the age, reported by Holmes[2], was explained by Wasserstein[3] by classifying uraninites into two different types—α-type for Bisundni uraninite and γ-type for Gaya uraninite, the latter being apparently anomalous and requiring heat treatment under oxidizing conditions in order to reduce the cell size to correspond to that of an α-type analogue. Wasserstein did not, however, state the temperature and period of heating and the conditions under which the cell size of γ-uraninite was reduced to correspond to age values consistent with those of the α-type.

A number of specimens of uraninite from Bisundni and Gaya from the collection in the Indian Museum made by H. Crookshank[4] and G. H. Tipper[5], and thorianite from Ceylon by A. K. Coomaraswamy[6], were used for the present study. The cell dimensions of Bisundni uraninites (a_0 5·436–5·440 Å.) and Gaya uraninites (a_0 5·459–5·467 Å.) are different from those reported by Wasserstein[1] (5·448 Å. for Bisundni and 5 481 Å. for Gaya). A thoria correction[1] of −0·0013 Å. for each percentage thorium oxide when ($ThO_2 + UO_2$) totals 100 per cent will reduce the cell size of Bisundni uraninite by 0·002 Å. (a_0 5·436 Å. mean value) and Gaya uraninite by 0·017 Å. (a_0 5·445 Å. mean value) if the ratio of uranium oxide to thorium oxide is calculated on the basis of Holmes's analysis (Table 1).

The finely powdered uraninite (a few mgm.) was heated at 800° C. in an open silica boat (1) within an electric muffle furnace and (2) also within a closed silica retort tube (of 2-cm. diameter placed inside an electric tube furnace at 800° C.) which was continuously evacuated to maintain a vacuum of the order of 10^{-2} mm. of mercury.

Table 1

The cell size was determined with an accuracy of ± 0 003 Å. using aluminium as internal standard with 114 59 mm. diameter Philips' powder camera having two fiducial marks and copper *Kα*-radiation ($\lambda = 1\cdot5405$ Å.).

Brooker and Nuffield[8] observed a shrinkage of the cell size of uranium dioxide (on heating in vacuum at 900° C. for 30 min.) of the order of 0 02–0·05 Å. depending on the degree of oxidation, the ratio of U^{4+} to U^{6+} in the original lattice, and reported the formation of the unknown compound *X* (U_3O_8 ?). In the present study (Table 1) the shrinkage of the cell size of uranium dioxide is followed by a close doubling of the higher-angle diffraction lines (development of an additional phase) and the formation of the compound *X*. The oxidation of uraninite out of contact with oxygen suggests that in the oxygen-rich lattice of natural uraninite the excess of oxygen occupies the available interstitial positions (½ 0 0) in six-fold co-ordination with uranium[9,10], and this shrinkage of cell size implies simultaneous replacement of U^{4+} cations (1·05 or 0·97 Å.) by the U^{6+} cations (0·80 Å.), that is, the substitution of cations of smaller ionic radii and higher charge, is preceded by readjustment of interstitial anions in the fluorite-type lattice (space group *Fm*3*m*). The cell size of 5·47 Å. for synthetic uranium dioxide decreases to 5·39 Å. for $UO_{2\cdot6}$, but the structure is preserved[8] even when the alteration of $U^{4+} : U^{6+} : O$ ratio apparently extends up to about $UO_{2\cdot6}$. The progressive reduction of the cell size of uranium dioxide due to the substitution of Pb^{4+} (0·84 Å.) for U^{4+} within the lattice with time (which has not been evaluated but only visualized by Wasserstein[1,2]) is likely to be quite negligible compared to the more pronounced shrinkage due to alteration of $U^{4+} : U^{6+} : O$ ratio in the oxygen-rich lattice of natural uraninite.

Moreover, lead in lower valency state (Pb^{2+} 1·21 Å.) is a greater possibility[11].

Wasserstein's proposed classification of thorianite into γ-type may be interpreted from the observed evidence on synthetic members of the series (U$_x$Th$_{1-x}$O$_2$) by Anderson *et al.*[12]. On high-temperature vacuum heating the type of interaction[13] between uranium and interstitial oxygen in the original lattice alters with the conversion of U^{4+} to U^{6+} and consequent shrinkage of the unit cell (Table 1); Th^{4+} ions do not react because of their reluctance to donate electrons.

I wish to thank Dr. B. C. Roy, director of the Geological Survey of India, for permission to publish this communication.

Silicon in the Metal Phase of Enstatite Chondrites

I HAVE recently measured the lattice parameters of the metal phases from a number of chondrites. In five common varieties the kamacite lattice parameter was within the range 2·8682 ± 0·0005 Å. This corresponds to an average of 5 per cent nickel in solid solution[1]. Owen and Burns[1] found that the kamacite lattice parameters from 15 meteoritic irons were within the range 2·8686 ± 0·00015 Å. This is in good agreement with the above result, and indicates the presence of about 6 per cent nickel. I also examined the kamacite from 6 enstatite chondrites. In these, the lattice parameters were found to be abnormally low, and below that of pure iron (Table 1). The metal phases of these chondrites had previously been analysed and found to contain normal amounts of nickel—between 6 and 8 per cent. Since the solid solution of nickel 'increases' the lattice parameter of pure iron, it was inferred that appreciable amounts of some other component were also present in solid solution and that this component had caused the lattice parameter to contract.

A process of elimination led to the conclusion that the additional component was silicon. This is the only element which forms extensive solid solutions with iron, causing marked contraction of the lattice parameter, and at the same time, occurs in sufficient quantities in chondrites to produce the observed contraction. A literature survey revealed that 2 (atomic) per cent of silicon had previously been recorded in the metal phase of the enstatite chondrite Blithfield[2]. Furthermore, in the metal phases of other enstatite chondrites—Khairpur[3], Daniels Kuil[3] and Saint Marks[4]—the analysts have commented upon an apparent 'excess' of silica, but could not account for its origin. Kamacite from three of the meteorites has been examined by X-rays. The lattice parameters were substantially less than that of pure iron, and it therefore seems highly probable that the excess silica found by the analysts was derived from elemental silicon in solid solution. The analytical results in Table 1 have been recalculated on this assumption.

Table 1. SOME PROPERTIES OF KAMACITE FROM ENSTATITE CHONDRITES

Reference	Meteorite	Atoms per cent nickel in kamacite	Lattice parameter of kamacite Å.	Atoms per cent silicon in kamacite from X-ray data	Atoms per cent silicon in kamacite from chemical data
2	Blithfield	6·4	2·8657	5	2·0
3	Daniels Kuil	6·2	2·8655	5	3·8
9	Hvittis	7·6	2·8655	5	
10	Indarch	6·7	2·8619	10·5	
3	Khairpur	7·0			1·9
11	Pillistfer	8·4	2·8652	6·5	2·6
4	Saint Marks	6·4	2·8632	9	18
12	Kamacite from five ordinary chondrites	Average 5	2·8680 ± 0·0005		
1	Kamacite from 15 meteoritic irons	6·2	2·8686 ± 0·00015		
	Pure iron	0	2·8665		

In all enstatite chondrites studied, the only metal phase present was kamacite.

A sample of kamacite was magnetically separated from a large sample of the Pillistfer enstatite chondrite and purified by grinding, repeated fusion with sodium hydroxide and washing on a superpanner. Chemical analysis of the pure kamacite has indicated the presence of approximately 2·6 atoms per cent of silicon. X-ray examination of this sample again revealed a contraction of lattice parameter compared to iron.

The variation of lattice parameters of iron–silicon solid solutions as a function of composition is well known[5]. If one makes the reasonable assumption that the relative variation is not greatly modified by the presence of 6–8 per cent of nickel in solid solution, it is possible to estimate the silicon content of kamacite from the difference between the observed lattice parameter and that of a normal iron–nickel solid solution of the relevant composition. These estimates are set out in Table 1.

The above results indicate that silicon is an important component of the metal phase of enstatite chondrites, the amounts present ranging between 2 and 18 atomic per cent. This occurrence is consistent with the highly reduced state of enstatite chondrites, which contain iron-free silicates and reduced chromium, calcium and phosphorus minerals (daubreelite, oldhamite, schreibersite).

Ringwood[6,7] and MacDonald and Knopoff[8] have independently suggested the presence of substantial amounts of silicon in the Earth's core. Occurrence of silicon in the metal phase of enstatite chondrites is very relevant to this hypothesis. A detailed discussion of the present results and their bearing upon this hypothesis will be published elsewhere.

I gratefully acknowledge the gift of meteorite specimens by Mr. O. Chalmers (Australian Museum), Dr. H. B. Wiik (Geological Survey of Finland), Dr. K. Fredriksson (Geological Survey of Sweden), and Mr. K. R. Dawson, Geological Survey of Canada.

METALLURGY

Formation of Beryllium Carbide during the Corrosion of Beryllium in Carbon Monoxide and in Carbon Dioxide Gas

Previous workers[1] have concluded from a comparison of the reaction between beryllium in dry carbon dioxide at 650° C. and in dry oxygen at 650° C. under kinetic conditions that the higher gain in weight of the specimen in carbon dioxide was due to the formation of beryllium carbide, which rendered the beryllium oxide non-protective. However, no metallographic evidence for the deposition on to the specimen of carbon, either as elementary carbon or as carbide, was given to support their hypothesis.

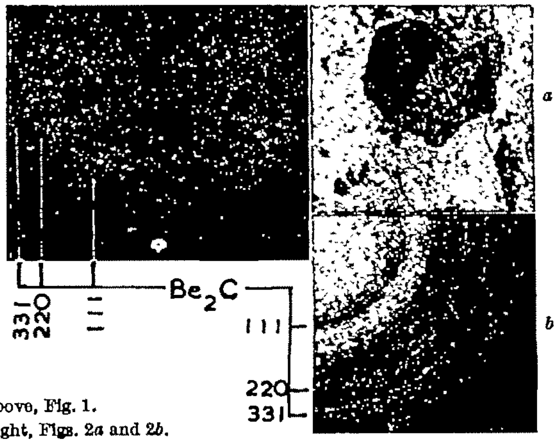
More recently (Jepson, W. B., and Antill, J. E., private communication), experiments designed to investigate the corrosion behaviour of beryllium using radioactive carbon monoxide and carbon dioxide under static conditions have shown that carbon (as the isotope carbon-14) is indeed deposited on the beryllium. Two typical specimens from this work have been examined by optical and electron microscopy and electron diffraction at the Atomic Weapons Research Establishment, Aldermaston, in order to locate the deposited carbon and to investigate whether beryllium carbide was formed.

The beryllium specimens were cut from rolled sheet 0·031 in. thick produced from French Flake beryllium. They were chemically polished and outgassed before insertion into the reaction vessel.

The first of the two specimens was heated at 700° C. in carbon monoxide and in this case spalling of the reaction product occurred. The uptake of carbon was measured from the decrease in count-rate of the gas, and the total gain in weight of the specimen was calculated from the measured volume of reacting gas.

A taper section through a piece of the specimen showed a well-defined boundary between the beryllium metal and the hard grey-looking scale on the surface, and immediately beneath this layer occurred a region some 100μ in depth of extensive cavitation which, by comparison with a corresponding section of as-received metal, was concluded to have been produced during the corrosion.

A reflexion electron diffraction pattern from the specimen surface is illustrated in Fig. 1. Measurement of the rings showed the presence of beryllium oxide, a hexagonal structure with $a = 2{\cdot}2679$ Å. and $c = 4{\cdot}380$ Å.[2], and in addition, three extra rings not attributable to beryllium oxide. Using the oxide rings for calibration these extra rings were found to have *d*-spacings of 2·51 Å., 1·53 Å. and 1·31 Å. respectively. No similar patterns have been presented in any previous corrosion work on beryllium. The crystal structure of beryllium carbide (Be_2C) is reported from X-ray observations[3] as of the anti-fluorite type, that is, cubic with $a = 4{\cdot}33$ Å. The first three carbide diffractions are given as (111), (220) and (311) with *d*-spacings of 2·51 Å., 1·53 Å. and 1·31 Å. respectively. The close agreement between the X-ray results and the present electron diffraction results is considered to be direct evidence for beryllium carbide having been formed during corrosion in carbon monoxide.



Above, Fig. 1.
Right, Figs. 2*a* and 2*b*.

Fragments of the corrosion product were stripped from the specimen using plastic films and the extraction replicas examined in the electron microscope. Particles ranging in size from 0·1 to 10μ were observed adhering to the replica. An electron diffraction pattern (Fig. 2*b*) from the edge of one particle of about 5μ diameter, Fig. 2*a* (× 4,000), is similar to Fig. 1 and clearly shows the presence of beryllium oxide and beryllium carbide. Some extracted particles gave only beryllium oxide diffractions, but no particles consisting entirely of beryllium carbide were observed.

Examination of a specimen subjected to carbon dioxide at 700° C. again gave diffraction patterns showing the formation of beryllium oxide and beryllium carbide.

From these experiments it is concluded that beryllium carbide is formed together with beryllium oxide during the reaction at 700° C. of beryllium with static carbon monoxide gas and also with static carbon dioxide gas, and that the carbide particles are dispersed within the oxide layer.

Thermodynamical results[4] indicate that free carbon could also be formed during the above reactions, although carbon was not identified in the present electron diffraction investigation. If, therefore, carbon is present in the reaction products it must be disseminated in such a way that there is an insufficient quantity accessible to the electron beam for detection.

Further work is in progress to study the diffusion of carbon into beryllium and the effect of the presence of the carbide phase on the mechanical properties of the metal.

I wish to thank Dr. W B. Jepson and Mr. R. J. Hussey of the Chemistry Department, University of Exeter, and Dr. J. E. Antill of the Metallurgy Division, Atomic Energy Research Establishment, Harwell, for providing the beryllium corrosion specimens. This work was carried out in the Crystallography Section of the Metallurgy Branch, Atomic Weapons Research Establishment, Aldermaston, under the direction of Dr. A. Moore.

Photo-stimulated Emission of Exo-electrons from the Surface Layer of Amphoteric Metals reacting with Concentrated Sodium Hydroxide or Potassium Hydroxide

WHILE studying the influence of liquids[1] on the tribo-excited emission phenomena of exo-electrons (Kramer effect[2]) from metals, we have found that the amphoteric metals like aluminium, zinc and tin as well as brass and some soldering alloys containing tin give a comparatively strong emission of exo-electrons when irradiated with visible light, after the freshly abraded surface is sprayed with strong concentrated sodium hydroxide or potassium hydroxide.

Aluminium gives this strong emission even when the surface is not abraded.

This emission can also be measured from abraded cadmium. In this case, we think the emission is due to traces of zinc impurity in the cadmium.

The intensity of measured photo-stimulated emission decreases with the thickness of the covering layer of sodium hydroxide or potassium hydroxide. This seems to be due to the absorption of exo-electrons from the metal-solution interface region.

In darkness no significant emission is detected.

The preliminary measurements seem to show that each of the amphoteric metals has a different 'decay constant' for the emission from their reacting surface layers.

The emission was measured in atmospheric air with the aid of a point counter with a grid. The pulses in the counter could be completely suppressed by a retarding potential applied between the grid and the reacting metal[3].

The observed effect is not due to the exothermic character of the reactions. To prove it, the reactions of abraded zinc and aluminium with concentrated hydrochloric acid have been examined using the same experimental conditions. In neither case was any photostimulated emission of exo-electrons observed.

The effect could not be observed for the metals iron, copper, bismuth, nickel, lead and magnesium when they were tested under the same experimental conditions.

Magnesium, which is known to give very intensive emission of exo-electrons under visible light after the abrasion of the surface (like aluminium) but which is known not to be amphoteric, shows a remarkable decrease of emission intensity after the emitting surface is sprayed with concentrated sodium hydroxide or potassium hydroxide. Aluminium, tin and zinc in contrast always show a strong increase under those conditions.

A detailed report will be published in *Acta Physica Polonica*.

Thin Films of Silver–Cadmium Alloy

WE have undertaken a detailed electron diffraction study of thin films of silver–cadmium alloy obtained by evaporating the constituent metals consecutively in vacuum. Films of various compositions have been formed in this way and their phases and structures identified.

Near equi-atomic composition of this alloy system a crystallographic transformation has been reported by many workers employing X-ray diffraction and other methods to occur in the bulk state[1]. By such studies it has been established that, in bulk state, the low-temperature β^1-phase (body-centred cubic ordered) structure changes to ξ-phase (closest-packed hexagonal) around 250° C., although the exact transformation temperature is a matter of controversy. Employing high-temperature electron diffraction technique, we have tried to investigate this transformation with the view of determining the exact transformation temperature in the case of thin alloy films. Careful and repeated observations with well-homogenized films about 500 Å. thick, giving a characteristic pattern of pure β^1-phase (body-centred cubic structure) at room-temperature, failed to reveal any change at all in the phase up to a temperature as high as 300° C. The study could not be extended to higher temperatures because of the rapid volatilization of cadmium from the alloy films, leaving the films less rich in cadmium and consequently changing to α-phase.

The details of the investigation will be published elsewhere.

CHEMISTRY

Preparation of Tritiated Water Samples by Distillation

IN many experiments using tritium as a tracer it is necessary to prepare a sample of pure water from organic material. During measurements of total body water using tritiated water in a dilution technique we have obtained pure water samples from urine by distillation. The urine is placed in a small vessel (Fig. 1) the bulb of which is put in an oil-bath maintained at 110° C. The distillate collects in the

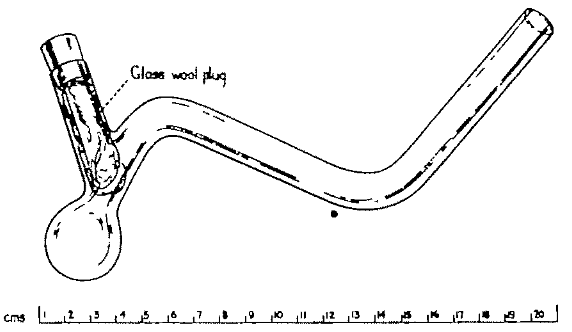

Fig. 1. Distillation tube

bend of the side-arm, which is cooled by a piece of wet paper or cloth. The glass-wool plug prevents urine frothing over into the side-arm. This technique has proved more effective and convenient than decolorizing with activated charcoal.

However, we were concerned that there might be a considerable isotope effect in the evaporation of ordinary and tritiated water, leading to the initial distillate being weak in tritium. The apparent 10 per cent difference in the molecular weights of water and HTO will be effectively reduced if water is associated at its boiling point, but the exact degree of association seems uncertain[1]. For a simple system containing water and HTO the relative evaporation rates of the two components would be expected to equal the ratio of the vapour pressures. This ratio has been measured by Price[2] between 25° and 80° C. Extrapolation of his results indicates a vapour pressure difference of about 4 per cent at the boiling point of water and a difference of boiling point of 1–2° C.

As the fractionation of liquids with different boiling points depends upon the exact conditions of distillation, particularly the reflux ratio, we distilled a water sample containing a known activity of HTO in our apparatus, collecting the distillate in four approximately equal fractions. The activities of all fractions and an aliquot from the original sample were measured by liquid scintillation counting. The major source of error was probably that associated with dispensing, as counting statistics contributed only about 0·1 per cent. The results are set out in Table 1.

Table 1

Specimen	Relative specific activity
Original sample	100
First quarter of distillate	99·7
Second quarter of distillate	99·7
Third quarter of distillate	100·3
Fourth quarter of distillate	100·4

It would appear that, with our apparatus, little separation of the isotopes occurs, and it is permissible to distil and measure only a fraction of the initial sample.

We are indebted to Dr. G. Boyd for suggestions regarding the distillation vessel.

Oxidation of Beryllium in Carbon Dioxide and in Carbon Monoxide

The metal beryllium has been suggested as a possible canning material in the advanced gas-cooled thermal reactor, so that its oxidative behaviour at elevated temperatures in carbon dioxide, carbon monoxide and mixtures of these two gases is of some technological importance. Published work on the oxidation of beryllium in carbon dioxide is limited to the investigation of Munro and Williams[1], which covered the temperature range 500–700° C.; here the course of the oxidation was followed by intermittent weighing, the sample being cooled to room temperature for each measurement. The purpose of this communication is to report briefly some of the results of a recent study of both the chemistry and the kinetics of the reaction between French Flake beryllium and carbon dioxide, carbon monoxide and their mixtures (usually at a pressure of 10 cm.) and at temperatures in the range 500–750° C. The samples were chemically polished before use.

With the aid of a specially developed radioactive tracer technique using carbon-14 labelled carbon dioxide, it has been established that when beryllium is oxidized in carbon dioxide, the following reactions occur:

$$\mathrm{Be} + \mathrm{CO_2} = \mathrm{BeO} + \mathrm{CO} \qquad (1)$$

$$2\mathrm{Be} + \mathrm{CO_2} = 2\mathrm{BeO} + \mathrm{C} \qquad (2)$$

There is no evidence for reaction[2] of deposited carbon with carbon dioxide:

$$\mathrm{C} + \mathrm{CO_2} \rightleftharpoons 2\mathrm{CO} \qquad (3)$$

or for the reaction:

$$\mathrm{Be} + \mathrm{CO_2} = \mathrm{BeO} + \mathrm{C} + \tfrac{1}{2}\mathrm{O_2} \qquad (4)$$

even though this is thermodynamically possible[3,4]. Chemical analysis of the reaction product shows that some 38 per cent of the deposited carbon is combined with beryllium as beryllium carbide. It is believed that the latter is formed after the carbon has been deposited, by the reaction:

$$2\mathrm{Be} + \mathrm{C} = \mathrm{Be_2C} \qquad (5)$$

rather than by:

$$4\mathrm{Be} + \mathrm{CO_2} = 2\mathrm{BeO} + \mathrm{Be_2C} \qquad (6)$$

The overall rate of reaction (oxide formation and carbon deposition) has been studied on a vacuum microbalance and at temperatures up to and including 700° C.; the rate of oxidation continuously decreases with time (Fig. 1) to reach a very small value after long periods, the rate after 300 hr. varying from 0·01 μgm./cm.^{2} hr. at 500° C. to 0·07 μgm./cm.^{2} hr. at 700° C. Oxidation is thus protective over the range 500–700° C., in general agreement with the results of Munro and Williams[1]. At 750° C., on the other hand, the rate of oxidation first decreases and then increases with time, indicating a breakaway reaction.

The amount of deposited carbon, both elementary and combined, in the oxide film is small, varying in a somewhat irregular manner with temperature from 1·8 μgm./cm.^{2} at 550° C. to 11 μgm./cm.^{2} at 750° C.

When the carbon dioxide is admitted to the outgassed sample at reaction temperature there is (see Fig. 1) a very rapid initial weight gain (which as a fraction of the total weight gain after 300 hr. varies

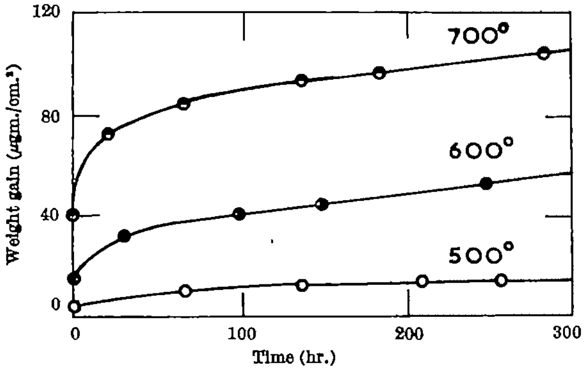

Fig. 1. Oxidation of beryllium in carbon dioxide at 500°, 600° and 700° C. The gas was admitted to the preheated sample

from 28 per cent at 500° C. to 41 per cent at 700° C.), and it appears that most of the carbon deposition occurs over this initial period; if, however, the beryllium was heated in carbon dioxide from room to reaction temperature, the initial gain in weight was no longer obtained, carbon deposition occurred over a longer period, and the amount deposited was less. The oxidation curves corresponding to these two differing modes of heating up the sample approach each other with increasing time.

For the oxidation of beryllium in carbon monoxide the reaction:

$$2Be + CO = Be_2C + \tfrac{1}{2}O_2 \quad (7)$$

is excluded on thermodynamic grounds[3,4] so that there are only the possibilities:

$$Be + CO = BeO + C \quad (8)$$

and:

$$3Be + CO = BeO + Be_2C \quad (9)$$

Since there are no volatile reaction products, kinetic measurements do not distinguish between reactions 8 and 9 and it is necessary to resort to chemical analysis of the reaction product. This shows that 15 per cent of the deposited carbon is chemically combined with beryllium as carbide and is probably formed by reaction 5 rather than reaction 9. There was no evidence for the decomposition of carbon monoxide on the surface, to deposit carbon and evolve carbon dioxide (reaction 3). For a given temperature, the rate of oxidation of beryllium in carbon monoxide is considerably greater than in carbon dioxide and a further important difference is that at 550° C. and above, the oxidation of beryllium in carbon monoxide is non-protective, the reaction product spalling from the sample during the run.

For oxidation in mixtures of carbon monoxide–carbon dioxide there is the possibility of reaction with either one or both of these gases, but runs at 650° C. in mixtures containing up to 7·5 per cent carbon monoxide showed that the oxidation followed the same course as in carbon dioxide alone. Supplementary measurements at a number of temperatures suggest that there exists a critical concentration of carbon monoxide above which the reaction changes from one with carbon dioxide to one with carbon monoxide, the rate of carbon deposition, and hence the rate of oxidation, then markedly increasing. At 700° C. this critical concentration of carbon monoxide is about 88 per cent by volume.

A detailed description and discussion of these results will be published elsewhere. We are grateful to Dr. J. E. Antill for several helpful discussions, and wish to acknowledge the financial support which this work has received from the United Kingdom Atomic Energy Authority.

Behaviour of Some Aldehydes on a Sulphonated Polystyrene Resin

5-HYDROXYMETHYL 2-FURALDEHYDE is a well-known product from the browning reaction[1] between certain sugars and amino-compounds. In the course of its isolation from such a reaction mixture it was assumed that it would be easily eluted, together with the unreacted sugar present, from a column of 'Zeokarb 225 [H⁺]' resin. Instead it was found that the volume of 0·3 *N* hydrochloric acid required to elute it was approximately 0·6 of that required to elute D-glucosamine. Passage of 2-furaldehyde and salicylaldehyde down the same column (Fig. 1) revealed that these were even more strongly absorbed. Since 5-hydroxymethyl 2-furaldehyde showed no evidence of behaving as a base on paper ionophoresis in either 0·75 *M* formate buffer *p*H 2 or 0·3 *N* hydrochloric acid, the explanation for its retention must lie in some other mechanism of interaction with this sulphonated polystyrene resin.

One possibility is that the aldehydes form weak addition compounds with the sulphonic acid function. By analogy with the reaction between benzaldehyde, benzene sulphonyl chloride and sodium cyanide,

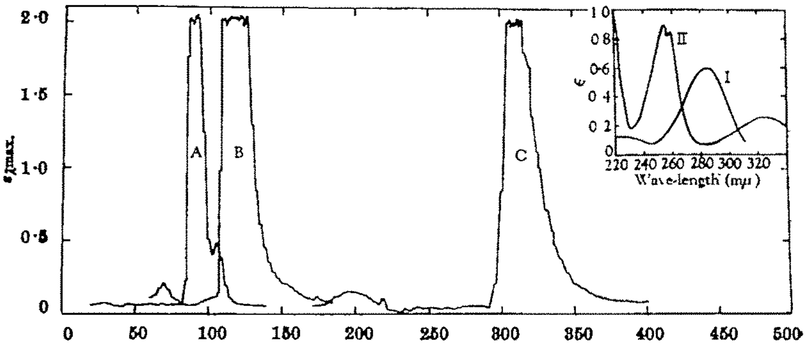

Fig. 1. Histogram showing the position of elution of 5-hydroxymethyl 2-furaldehyde (*A*), furfuraldehyde (*B*) and salicylaldehyde (*C*) from a column of sulphonated polystyrene resin ('Zeokarb 225'). Inset are the absorption curves of 5-hydroxymethyl 2-furaldehyde (I) and salicylaldehyde (II)

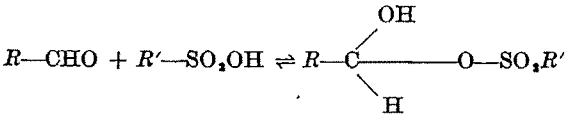
which afforded α-cyanobenzyl benzene sulphonate[2], this addition compound could be formed thus:



$$R\text{—CHO} + R'\text{—SO}_2\text{OH} \rightleftharpoons R\text{—}\overset{\text{OH}}{\underset{\text{H}}{\text{C}}}\text{—O—SO}_2R'$$

Another factor influencing the absorption of the aldehydes could be van der Waals adsorption forces, since it is known that compounds containing aromatic residues are adsorbed on polystyrene ion-exchange resins[3-5]. 'Amberlite *IR* 120 (H^+)', which is equivalent to 'Zeo-Karb' 225 [H^+]', has been used[6] to separate phenol, *p*-cresol and 4-tert. butyl phenol. Gabrielson and Samuelson[7] have investigated the adsorption of aldehydes and ketones on 'Amberlite *IRA*-400' (bicarbonate form), which is an anion exchanger of the strongly basic type. They reported that salicylaldehyde and vanillin were strongly absorbed, whereas formaldehyde, acetaldehyde and 2-furaldehyde were eluted almost quantitatively. In this case absorption was attributed to the acidic character of the two aromatic aldehydes.

The unexpected property of derivatives of 2-furaldehyde may prove useful not only in the identification of intermediates in the browning reaction but also those products of acidic degradation of sugars which form the basis of so many colour reactions for the quantitative determination of sugars.

Symmetry of Insulin Dimers and Hexamers

RECENT X-ray crystallographic studies of orthorhombic crystals of bovine insulin sulphate have provided information about the symmetry of the insulin dimer (molecular weight 2 × 5733). This dimer appears to be the stable unit in acid aqueous solution, except under special conditions[1]. The dimer is the protein component of the asymmetrical unit in the wet, type *A* and type *B* sulphate and type *A* citrate, crystals[2], and also in the air-dried sulphate crystals[3]. Studies of the shrinkage stages of the type *A* insulin sulphate crystals[4] have disclosed the existence of several new crystal forms. The space group of all but one of these is $P2_12_12_1$ ($Z = 4$), that of all previously examined orthorhombic insulin crystals. One shrinkage stage (type *C*) has the space group $I2_12_12_1$ ($Z = 8$). In this crystal twofold rotation axes relate pairs of insulin molecules. On the basis of crystallographic and other evidence, it was possible to establish the strong probability that the insulin dimer has basically an invariant structure, with point group 2, in all these crystal forms and in acid solution; that is, the two insulin molecules of the dimer are related to each other by a twofold rotation axis.

This conclusion was strengthened by Patterson studies of the wet type *A* insulin sulphate crystals[5]. The position of the highest non-origin peak in the three-dimensional Patterson function is that of a pseudo-origin in each of two Patterson projections—that is, the distributions of peaks about this position are similar to those about the origins of these projections. However, the pseudo-origin character appears slight or non-existent in the third (*a*-plane) projection and in the three-dimensional Patterson function. These observations have been explained on the basis of a non-crystallographic twofold (or pseudo-twofold) rotation axis parallel (or nearly parallel) to *a*. Given two independent sources of evidence, the symmetry, or, if the dimer structure is not invariant, at least the pseudo-symmetry, of the insulin dimer seems to be established.

The predominant insulin species in solution near neutral *p*H is the hexamer[1b]. A threefold rotation axis relating three dimer units has been found in rhombohedral zinc insulin crystals, space group *R*3, grown under these *p*H conditions[6]. It appears to us that the dimer as a subunit of the hexamer may well have the point group 2. Indeed, it is quite possible that the hexamer has the point group 32 with each single molecule equivalent. (If the hexamer has the point group 32, then the three twofold rotation axes relating the molecules to each other in the dimer subunits lie in a plane normal to the threefold axis and at angles of 120° to each other.) If non-crystallographic twofold axes should exist in the rhombohedral zinc insulin crystal form, they should be detectable, with greater or lesser ease dependent upon their orientation to the threefold axis, by analysis of the vector structure.

This investigation was supported by a senior research fellowship *SF*-246*C* from the Public Health Service to one of us (B. W. L.). It was carried out during the tenure of a National Science Foundation post-doctoral fellowship (J. R. E.).

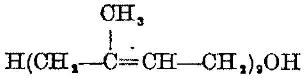
BIOCHEMISTRY

Dolichol: a Naturally Occurring Isoprenoid Alcohol

IN 1956[1] a long-chain isoprenoid alcohol, solanesol, was isolated from tobacco and tobacco leaves. While searching for solanesol in animal tissues we have isolated an isoprenoid alcohol of greater chain-length for which we propose the name 'dolichol'.

The characterization of ubichromenol from 46·5 kgm. of human kidney has been described[2,3]. Two fractions weighing 6·41 gm. were eluted between ubiquinone and ubichromenol on chromatography. The infra-red spectrum of the bulked material strongly resembled that of an isoprenoid alcohol[4]. Dolichol was purified from these fractions by forming the acetate, which was then chromatographed, crystallized from ethanol–petrol, and finally saponified to regenerate the alcohol. The alcohol was then crystallized from ethanol–petrol. Both the alcohol and the acetate were colourless viscous liquids at room temperature and white crystalline compounds at low temperature.

Dolichol showed no specific absorption in the ultra-violet region and its infra-red spectrum (all infra-red spectra were examined as films) was very similar to that of solanesol.



$$H(CH_2-\overset{CH_3}{\overset{|}{C}}=CH-CH_2)_9OH$$

Both showed bands indicating a hydroxyl, unconjugated double bonds and the *trans* configuration of those double bonds. The infra-red spectrum of solanesol, however, showed a band at 10μ due to the presence of the allylic alcohol grouping. Dolichol, on the other hand, showed C—O stretching absorption at 9·4μ. Hydrogenation of solanesol and dolichol gave their perhydro-derivatives, and the infra-red spectra of these materials were identical apart from differences in relative intensities consistent with a difference in chain-length. In particular, both saturated materials showed hydroxyl deformations due to the C—O stretching absorption at 9·4μ, and it would seem likely that dolichol contains a primary alcohol grouping but with no αβ-unsaturation.

The analysis of dolichol (C : 86·07 ; H : 12·18 ; C—CH_3 : 16·64 per cent) fitted a very long chain isoprenoid monohydric alcohol. A molecular weight determination by depression of the freezing point of *cyclo*hexane gave a value of 1,200.

The *p*-phenylazobenzoyl and *p*-nitrobenzoyl esters of dolichol were formed by refluxing with the acid chloride in pyridine. The esters were purified by chromatography on alumina, and the *p*-phenylazobenzoate could be crystallized from ethanol–petrol at low temperature. The ultra-violet absorption spectra of these esters were examined and were compared with the esters formed from other alcohols (Table 1).

Table 1. ULTRA-VIOLET ABSORPTION (IN *cyclo*HEXANE)

p-Phenylazobenzoates (λ_{max} at 324 mμ)

	E(1%, 1 cm.) 324 mμ	Molecular weight of ester	ε 324 mμ
Dolichyl	171·3	—	—
Farnesyl	616·6	430 6	26,550
Cholesteryl	438 0	594·9	26,060
Solanesyl	330·0	839·3	27,700

p-Nitrobenzoates (λ_{max} at 256 mμ)

	E(1%, 1 cm.) 256 mμ	Molecular weight of ester	ε 256 mμ
Dolichyl	95·0	—	—
Farnesyl	379·5	371·5	14,090
Phytyl	303·5	445·6	13,520

The mean molecular extinction value (ε) for the *p*-phenylazobenzoates was 26,770 and from this and the *E*(1%, 1 cm.) of dolichyl *p*-phenylbenzoate the molecular weight of the ester was calculated as 1,563. The molecular weight of dolichol was therefore 1,354. Similarly the mean molecular extinction coefficient for the *p*-nitrobenzoates was 13,800 and hence the molecular weights of the ester and dolichol were 1,453 and 1,300 respectively. A terpenoid alcohol with 19 isoprene residues, $C_{95}H_{153}OH$, has a molecular weight of 1,312 while one with 20 isoprene units, $C_{100}H_{161}OH$, has a molecular weight of 1,380.

The degree of unsaturation of dolichol and dolichyl acetate was examined by determining their iodine values (Dam's method) and by quantitative catalytic hydrogenation (for method see ref. 3). Table 2 shows that the results are in accord with dolichol being a long-chain isoprenoid alcohol.

Table 2. DEGREE OF UNSATURATION

	Double bonds	Moles H_2/100 gm.	gm. I_2/100 gm.
Dolichol		1 465	382 0
$C_{95}H_{153}OH$	(19)	1·448*	367 5*
$C_{100}H_{161}OH$	(20)	1·449*	367·9*
Dolichyl acetate		1·424	369·4
$C_{95}H_{153}O.COCH_3$	(19)	1·404*	356 2*
$C_{100}H_{161}O.COCH_3$	(20)	1·406*	357 0*

* Calculated.

Allylic alcohols will react readily with manganese dioxide[5] to produce αβ-unsaturated aldehydes but saturated alcohols are oxidized by manganese dioxide only with difficulty[6]. Farnesol was refluxed with excess manganese dioxide in petroleum ether (40–60°) for 1 hr. and gave a good yield of farnesaldehyde. Refluxing dolichol and manganese dioxide for 2 hr. in petroleum ether gave a smaller yield of a product which could be crystallized from ethanol–petrol after chromatography on alumina. The product showed only feeble ultra-violet absorption in *cyclo*hexane. The infra-red spectrum of the product showed no hydroxyl band but absorption at 5·75μ characteristic of a saturated aldehyde. Farnesaldehyde showed a band at 5·97μ characteristic of an αβ-unsaturated aldehyde with another band at 6·21μ due to the double bond conjugated to the carbonyl. It seems quite probable that the product from oxidation of dolichol was the expected aldehyde, dolichaldehyde.

Treatment of dolichaldehyde and farnesaldehyde with a saturated solution of 2 : 4-dinitrophenylhydrazine in 1 per cent ethanolic hydrochloric acid gave the corresponding derivatives, which were purified by chromatography on alumina and crystallization at low temperature. The farnesaldehyde derivative showed in ethanol $\lambda_{max.}$ 382–385 mμ, ε = 29,760, while dolichaldehyde 2 : 4-dinitrophenylhydrazone showed $\lambda_{max.}$ 360 mμ *E*(1%, 1 cm.) 156·1 (for a molecular weight of 1,312 the molecular extinction coefficient is 20,480). Derivatives of 2 : 4-dinitrophenylhydrazine with no αβ-double bond normally give rise to maximal absorption near 360 mμ with molecular extinction coefficients of 20,000–23,000[7]. A double bond in conjugation with the dinitrophenylhydrazine chromophore causes a bathochromic shift with an increased intensity as shown by the farnesaldehyde derivative.

Ozonolysis of dolichyl acetate yielded acetone and lævulinaldehyde, which were characterized as their 2 : 4-dinitrophenylhydrazones.

It is apparent that the molecule contains 19 or 20 isoprene residues* with a primary alcoholic group. This alcohol grouping has no αβ-unsaturation as in solanesol and the double bond may have been displaced to give βγ-unsaturation or a vinyl grouping. Dolichol has also been isolated from ox kidney, pig kidney, pig heart, pig liver, rat liver and ox intestine.

**Note added in proof*. Specially purified dolichyl acetate has molecular weight 1,422 (20 isoprene residues). We are indebted to Messrs. Hoffmann

La-Roche, of Basle (through Drs. O. Isler, U. Gloor and J. Würsch), for this result, based on isotope dilution of ^{14}C-labelled acetate.

Fractionation of Heparin on an Anion Exchanger

Preparations of heparin have been shown to be heterogeneous by a variety of techniques[1,2], but no method is available for the fractionation of bulk quantities of heparin or of other sulphomucopolysaccharides. These compounds carry a strong negative charge over a wide range of *p*H, and, therefore, it seemed possible that they could be purified on basic resins. Five anion-exchange resins ('Dowex-1', 'Dowex-2', 'Dowex-3', 'Amberlite *CG*-45', and 'Duolite *A*-4'), each buffered at *p*H 6·0, readily adsorbed heparin, which was easily eluted with strong salt solutions, but the eluates differed from the original material in having greater absorption at 400 mμ than at 535 mμ in the carbazole reaction[3]. However, 'Ecteola'[4,5] (exchange capacity = 0·3 m.equiv./gm.) resolved a commercial preparation of bovine heparin (obtained from Nutritional Biochemicals Corp.) into four major and one minor carbazole-positive fractions (Fig. 1), each with maximum absorption at 535 mμ, and all showing metachromasia[6]. 90 per cent of the original material was recovered. Heparin-^{35}SO$_4$, extracted from a mast-cell tumour of the mouse[7], gave only one peak on chromatography on 'Ecteola' (Fig. 2), and only 50 per cent of the material was eluted.

Independently, Mozen (personal communication) has used 'Ecteola' for the resolution of heparin and found that those fractions that came off the column latest had the highest anti-coagulant potency, as well as the highest sulphate content.

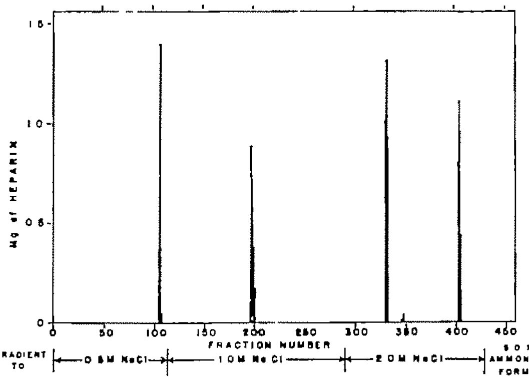

Fig. 1. Chromatography of 10 mgm. of heparin on 'Ecteola' (10 gm.; 2 × 9 cm.; flow-rate 4·0 ml./hr.). The heparin was applied in 100 ml. water. A gradient elution system was used, with a single mixing chamber containing 400 ml. water. Each fraction contained 5·5 ml.

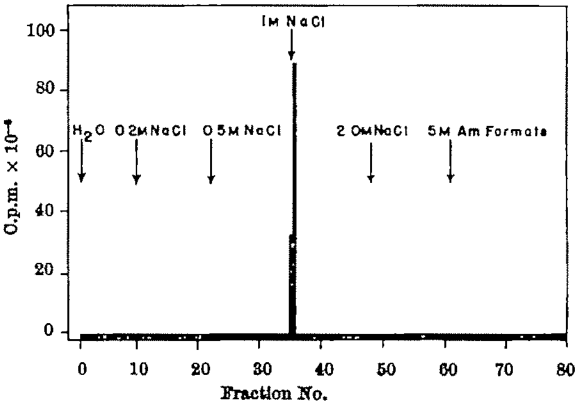

Fig. 2. Chromatography of mouse mast-cell heparin-^{35}SO$_4$ on 'Ecteola'. Each fraction contained 10 ml.

This work was supported by the American Heart Association and the Life Insurance Medical Research Fund. I am indebted to Dr. Margaret Day for providing the mast-cell tumour and to Miss Bella Wu and Mr. Mark Lavietes for technical assistance.

Mammalian α-L-Fucosidase

According to our surmise that the enzymes, β-N-acetylglucosaminidase, α-mannosidase and β-galactosidase, with their particularly high activity in the epididymis[1,2], are concerned in the breakdown of mucosubstances, they should be accompanied by an L-fucosidase. Serological evidence suggests that the L-fucose (6-deoxy-L-galactose) residue present in many mucopolysaccharides has the α-configuration[3,4]. Rat epididymis has now been found to have an α-L-fucosidase activity of about 20,000 units per gm. moist weight, compared with activities of about 4,000 units per gm. in organs such as liver, where 1 unit of enzyme liberates 1 μgm. *p*-nitrophenol in 1 hr. at 37° from *p*-nitrophenyl α-L-fucoside in an arbitrary concentration of 1 m*M*. The maximum activity is displayed at about *p*H 6. There is no α-D-fucosidase activity in mammalian tissues, but the limpet, *Patella vulgata*, with a high α-L-fucosidase activity, has a feeble effect on the related α-D-fucoside. This may well be a side-action of α-D-galactosidase.

Whereas β-glycosidases are always inhibited by the aldonolactones of corresponding configuration, the α-glycosidases only sometimes display this phenomenon[5,6]. It was shown that the hydrolysis of either of the α-fucosides was not depressed by the appropriate fuconolactone. Attempts to prepare suitable β-fucosides for enzyme work have thus far been unsuccessful.

Supercontraction of Wool Fibres and Creep in the Post-yield Region

It is now well established that hydrogen bonding takes a major role in the stabilization of wool keratin. This is well demonstrated by the recent finding[1] that wool fibres supercontract by 70 per cent of their length in 1 *N* hydrochloric acid containing 4 *M* concentrations of sodium iodide. In agreement with earlier workers[2], it was considered that the process took place in two phases corresponding to areas of strong and weak hydrogen bonding lying in series along the microfibrils.

I have been applying this technique to wool samples exhibiting marked variations in their post-yield creep properties and have noted two significant features.

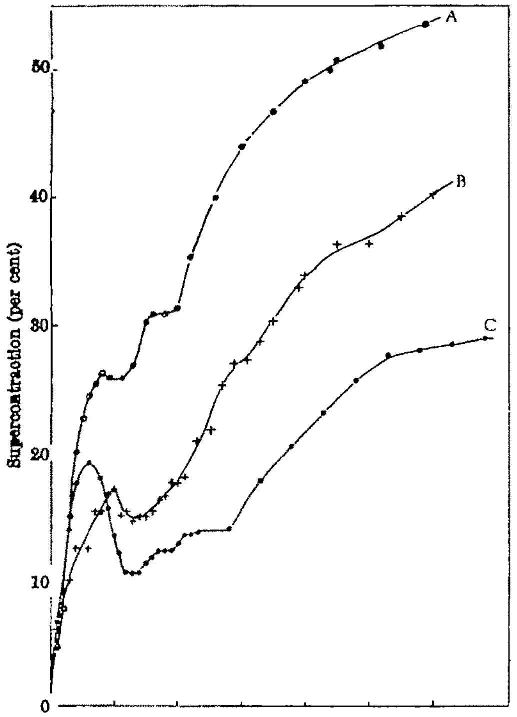

Fig. 1. Typical kinetic contraction curves of single fibres drawn from samples *A*, *B* and *C* at 98·5° C. in 1 *N* hydrochloric acid containing 4 *M* concentrations of sodium iodide

First, as has already been observed, there are large variations between samples (Fig. 1) and between fibres drawn from the same sample. Secondly, the later stages of the 1 hr. supercontraction bear a relation to the post-yield creep of the fibres (Table 1).

Table 1

Sample	Creep constant (arbitrary units)
A	53·6
B	21·9
C	13·5

It appears, therefore, that the 'strong' hydrogen bonds responsible for the later phases of supercontraction may also account for a major part of the technologically significant variations in the creep properties of wool fibres[3].

PHYSIOLOGY

Absence of Catecholamines in Cardioactive Acetone Extracts of Ox Spleen

It has been shown that acetone extracts of freeze-dried ox spleen are capable of stimulating hypodynamic papillary muscle[1]. Evidence has been reported recently[2] which suggests that the cardio-activity cannot be explained in terms of choline or its esters, histamine, 5-hydroxytryptamine, adrenaline or noradrenaline. Further experiments reported below confirm the absence of catecholamines in an active extract.

The amplitude of cardiac contractions was recorded by a Cushny myocardiograph sutured to the right ventricles of artificially respired guinea pigs anæsthetized with pentobarbitone sodium (45 mgm./kgm. intraperitoneally). The animals were pretreated with atropine sulphate (2 mgm./kgm. subcutaneously), promethazine hydrochloride (5 mgm. intramuscularly) and ergotamine tartrate ('Gynergen') 0·15 mgm./kgm. intramuscularly. A small moistened cotton-wool cover was arranged to prevent drying of the thoracic tissues without interfering with the movements of the heart, lungs or myocardiograph. Injections of drugs were made into the right jugular vein in small volumes, approximately 0·1 ml., and washed into the circulation with 0·2 ml. normal saline.

Injection of 1–2 μgm. noradrenaline caused transient positive inotropic actions which were approximately matched by 10–25 mgm. doses of spleen extract (corresponding to quantities of fresh spleen between 6·7 and 17·2 gm.). Following doses of dichloro*iso*prenaline, a specific antagonist to the inotropic and chronotropic actions of the catecholamines[3], the effects of noradrenaline were almost completely abolished, whereas the inotropic effect of the spleen extract was not significantly altered (Fig. 1).

Further evidence that the inotropic principle in extracts of spleen differed from the catecholamines was obtained from paper chromatographic tests using Vogt's[4] modification of the technique described by Crawford and Outschoorn[5] using an atmosphere

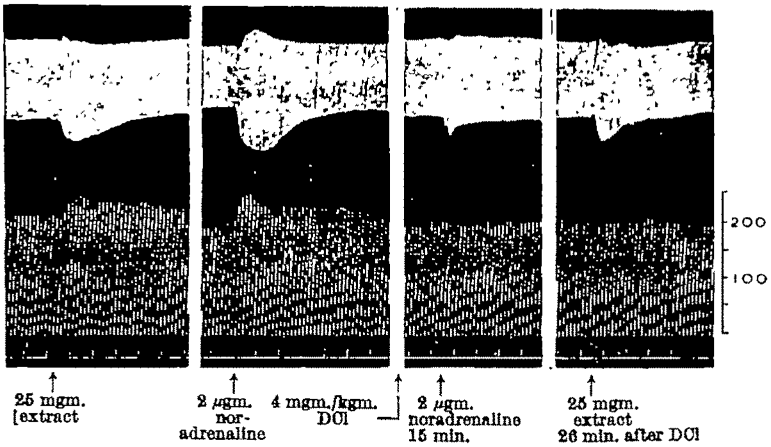

Fig. 1. Effect of dichloroisoprenaline (DCI) on the inotropic and chronotropic effects of noradrenaline and spleen extract in the intact anæsthetized guinea pig

of carbon dioxide in the tank. Samples of spleen extract sufficient to cause inotropic effects on papillary muscles in a 20-ml. bath were applied to Whatman No. 1 paper from a concentrated solution. Adrenaline, noradrenaline and dopamine (3-hydroxy-tyramine) were applied in 10-μgm. quantities to the paper. After development and removal of solvents, the chromatogram was sprayed with the ferricyanide reagent of James[6]. The catecholamines showed up clearly and good separation was achieved from a mixture. No colour reaction was observed with the samples of spleen extract, indicating that catecholamines were not present in significant quantities.

This evidence, together with that previously reported[2], seems to point conclusively to the absence of catecholamines in acetone extracts of freeze-dried spleen and suggests that the inotropic activity of these extracts is due to some other factors.

We are indebted to Dr. C. E. Powell for a generous gift of dichloro*iso*prenaline.

Active Transport of γ-Aminobutyric Acid in Brain Cortex Slices, with Special Reference to Phosphorus-32 Turnover of Phospholipids in Cytoplasmic Particulates

WHEN slices of guinea pig brain cortex were incubated aerobically at 37° C. in a saline medium containing amino-acid such as γ-aminobutyric acid or glutamate, the amino-acid was accumulated in the brain slices actively from the medium against its concentration gradient in the presence of glucose as a substrate. Terner *et al.*[1] reported that L-glutamate accumulated in brain slices accompanied by potassium ions when they were incubated aerobically in the medium containing glucose. Also as reported previously[2], non-metabolizable D-isomer of glutamic acid accumulated in the brain slices in the same manner.

If γ-aminobutyric acid, a neutral amino-acid, which has an important effect on nervous functions, was present in the medium in the concentration of 5 m*M* instead of glutamate, it also accumulated actively in the brain slices depending upon energy-yielding processes (Table 1). In this case, however, there was very little change in the intracellular potassium and water content on a dry-weight basis calculated by chloride assumption. The active transport of γ-aminobutyric acid in the slices was observed only with brain tissue, not with liver or kidney. In calcium-free medium, γ-aminobutyric acid was more actively transported in the slices; on the other hand, on omitting potassium ions from the medium, γ-aminobutyric acid transport was markedly suppressed (Table 1). By the addition of pyridoxal in the concentration of 1 m*M*, the accumulation of γ-aminobutyric acid was also augmented remarkably just as in the case of glycine uptake by carcinoma cells, as described by Christensen *et al.*[3].

Slice/medium ratio indicated in Table 1 was indicative of amino-acid transport in the slices. If this value represents more than 1·0, γ-aminobutyric acid should accumulate actively from the medium against its concentration gradient, since the intrinsic concentration of the acid in the nerve cell might be considered to be about 5 m*M*/kgm. as in the medium. Under these conditions, only γ-aminobutyric acid is transported across the cell membrane as a neutral substance without any considerable movements of extra cations.

We were interested in the carrier system of γ-aminobutyric acid transportation across the nerve cell membrane against the concentration gradient in relation to phosphorus-32 turnover of phospholipid

Table 1. ACCUMULATION OF AMINO-ACID INTO GUINEA PIG BRAIN CORTEX SLICES

Conditions	Amino-acid slice/medium ratio	(Cl-space) Intracellular water (ml./gm. dry weight)	(Cl-space) Intracellular K+ (m.equiv./gm. dry weight)
		Mean ± *S.D.*	
No substrate	None	1·65 ± 0·12 (4)	0·203 ± 0·05 (4)
Glucose–Ringer		1·85 ± 0·20 (11)	0·368 ± 0·01 (11)
With γ-aminobutyric acid (5 m*M*)			
No substrate	2·30 (3)	1·75 ± 0·24 (5)	0·194 ± 0·048 (5)
Glucose–Ringer	3·60 (4)	2·06 ± 0·56 (4)	0·380 ± 0·022 (4)
+Calcium-free	4·06 (5)	2·22 ± 0·10 (3)	0·320 ± 0·014 (3)
+Potassium-free	1·89 (4)	1·56 ± 0·42 (3)	0·177 ± 0·038 (3)
+Pyridoxal (1 m*M*)	4·96 (2)		
+2,4-Dinitrophenol (5×10^{-5} *M*)	2·59 (2)		

Slices were incubated in Krebs–Ringer phosphate (sodium, 140 m.equiv./l.; potassium, 7·26 m.equiv./l.; calcium, 2·75 m.equiv./l.; magnesium, 2·62 m.equiv./l.; chloride, 139 m.equiv./l.; phosphorus, 10·8 m*M*/l.) with 5 m*M* γ-aminobutyric acid. Amino-acids were measured paper chromatographically by ninhydrin colour development. Sodium and potassium were estimated by flame photometry and chloride by Lowry's method (ref. 7) after the extraction of dried tissue by 0·1 *N* nitric acid.

Table 2. PHOSPHORUS-32 INCORPORATION INTO PHOSPHOLIPID FRACTIONS OF CYTOPLASMIC PARTICULATES OF GUINEA PIG BRAIN

	Specific activity	Increase (per cent)	Total counts (c.p.m./gm. tissue)		
			Phosphatidic acid	Phosphatidyl-choline	Mono-phospho-inositide
Control	118	100	6,050	379	2,070
+γ-Amino-butyric acid (5 m*M*)	154	131	8,880	520	1,170
+Calcium-free +γ-amino-butyric acid	190	161	11,200	1,190	2,350
+Potassium-free + γ-amino-butyric acid	116	98	5,930	509	1,620
+Pyridoxal (1 m*M*) + γ-amino-butyric acid	189	160	15,900	882	1,420
Potassium-rich (sodium, 90 m*M*; potassium, 50 m*M*)	312	264	14,300	2,610	2,740

Slices were incubated in 2-ml. medium containing equal radioactivity of phosphorus-32. Specific activity was expressed as the value of the counts per min. per phospholipid phosphorus. The total counts of each phospholipid represented as counts per min. per gm. wet weight tissue.

fractions in brain tissue, which are present in fairly high concentration in the membrane structure. Guinea pig brain cortex slices (300–400 mgm.) were incubated for 60 min. in the medium containing 5 m*M* γ-aminobutyric acid and phosphorus-32 as a tracer. After the incubation period, slices were homogenized in 0·25 *M* sucrose in the cold. The cytoplasmic particulate fraction was obtained by centrifugation at 40,000 r.p.m. (105,000*g*) for 15 min. in the cold after the removal of cell debris; then the particulates were washed once, resuspended in 0·25 *M* sucrose and centrifuged again. Ethanol/ether (1 : 1) soluble lipids were extracted in the acidic state at 4° C. overnight from the cytoplasmic particulates fraction. The phospholipids extracted were separated by chromatography on silicic acid-impregnated paper with di*iso*butylketone/acetic acid/water in the proportions of 40 : 30 : 7 as described by Hokin *et al.*[4]. A contact radioautogram was taken with X-ray film. The identification of spots on the radioautogram was made by reference to the mild alkaline hydrolysis method of Dawson[5] rather than Hokin's procedure.

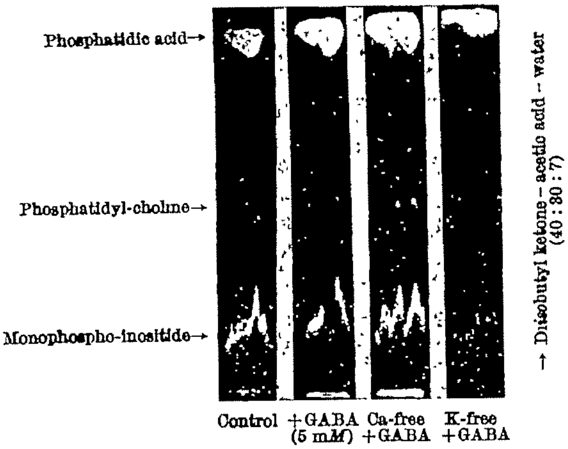

Fig. 1. Phosphorus-32 radioautogram of phospholipid in brain particulates

The incorporation of phosphorus-32 into the phospholipids, particularly phosphatidic acid and phosphatidyl choline, in the washed cytoplasmic particulate fraction was clearly increased accompanied by the accumulation of γ-aminobutyric acid in the slices. Moreover, on the addition of calcium-free medium or of pyridoxal (1 m*M*), phosphorus-32 incorporation was accelerated. On the contrary, when γ-aminobutyric acid did not accumulate in the slices on the condition of potassium-free medium, incorporation of phosphorus-32 in the phospholipids was diminished as shown in Table 2 and Fig. 1.

As reported previously[6], potassium-rich medium containing sodium ions (potassium : 50 m.equiv./l., sodium : 90 m.equiv./l.) stimulated the metabolism of brain slices such as oxygen uptake, glycolysis and incorporation of phosphorus-32 into phosphoprotein fractions. In these circumstances, the incorporation of phosphorus-32 into phospholipids of brain cytoplasmic particulates was also strongly stimulated. This suggests that some relationship exists between active transport of cations such as potassium influx and sodium efflux across the cell membrane and phosphorus-32 turnover of phospholipids.

From these results, phospholipids in cytoplasmic particulates of brain tissue, which are thought to be a main structure of the cell membrane electronmicroscopically, would play an important part as carriers in the active transport of amino-acid or cations across the nerve cell membrane.

Details will be published elsewhere later.

Histophotometrical Study of the Effect of Interstitial Cell-stimulating Hormone on the Deoxyribonucleic Acid Content of the Testicular Interstitial Cell Nucleus in the Adult Rat

IN our investigations of the relation between cell activity and deoxyribonucleic acid content of the nucleus in endocrine glands, we had the opportunity to study the influence of stimulation of the testicular interstitial cells by means of interstitial cell-stimulating hormone on the mean deoxyribonucleic acid content of their nuclei.

Ten male adult rats, 7–8 months old, were used. While 5 of these were controls, to each of the other rats 50 I.U. of interstitial cell-stimulating hormone have been given intramuscularly per 24 hr., for 14 successive days. All animals were beheaded simultaneously. The testes were fixed in alcohol/

	Average	1,198	3·0784	250	0 0561	0 00348

formalin/acetic acid (75 : 20 : 5) and cut at 10μ. Sections were prepared on the same slide in order to submit them to the Feulgen reaction under identical conditions. The deoxyribonucleic acid content was measured in individual nuclei by the histophotometrical method of L. Lison[1] and expressed in arbitrary units.

Table 1 summarizes the results ; since the individual nuclear contents vary following a log-normal distribution, the log $\bar{x}$ values were used for statistical computations.

When comparing the pooled results of the two groups, it is seen that after treatment with interstitial cell-stimulating hormone there is an 8·7 per cent increase in the mean deoxyribonucleic acid content of the nuclei of the interstitial cells (t = 7,651 ; $P \ll 0{\cdot}001$). These results demonstrate once more a stimulation of cell activity accompanied by increase of the mean deoxyribonucleic acid content of the nuclei.

Spontaneous Potential Changes at Crayfish Neuromuscular Junctions

An important feature of vertebrate neuromuscular transmission is that acetylcholine is released from the nerve terminals in 'packets'. At rest, a spontaneous discharge of these packets gives rise to 'miniature end-plate potentials'[1]. We were therefore interested whether this mechanism of transmitter release also occurs at a non-cholinergic crustacean neuromuscular junction.

In the abductor of the dactylopodite of the first walking leg of the crayfish (*Orconectes virilis*), spontaneous potentials of up to 0·8 mV. were recorded with intracellular electrodes (20–25° C., pH 7·2). The time course of these potentials (Fig. 1*A*) was similar to that of an excitatory junctional potential set up by stimulation of the motor axon. The largest spontaneous potentials were found in those fibres with the smallest diameters (about 100μ) and a relatively high input resistance (about 0·5 MΩ). They could be recorded from any point in the muscle fibre, in the same manner as excitatory junctional potentials[2]. The amplitude of consecutive spontaneous potentials varied considerably (Fig. 1*B*). Smaller potentials seemed to have a longer rise time (Fig. 1*A*), suggesting that they arose at a greater distance from the recording electrode. Frequencies in different fibres were between 0·1 and 10 per second. The potentials appeared to occur at random intervals. Statistical tests[3] confirmed that there was no noticeable interaction between single events. Our findings are similar to those of Burke[4], who recorded 'miniature end-plate potentials' in the frog's slow muscle fibres which also have motor nerve endings distributed over the entire fibre surface.

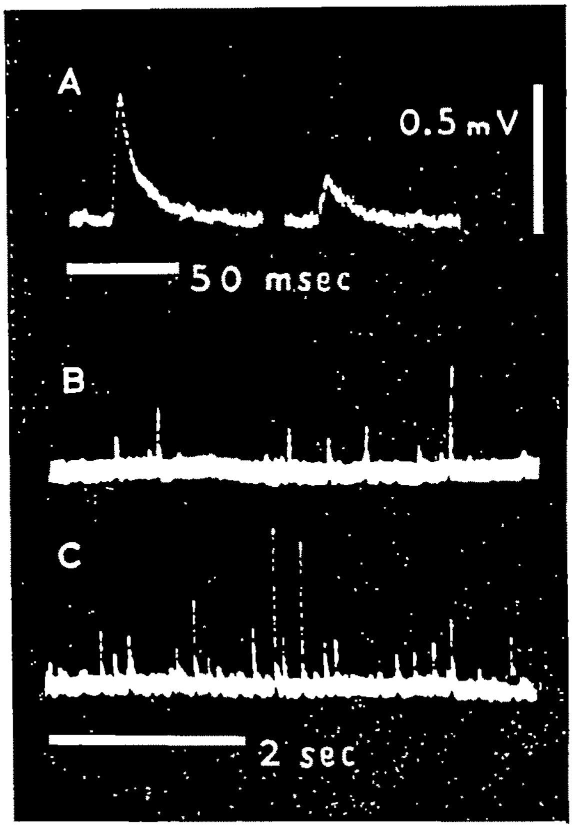

Fig. 1. Spontaneous potentials from a crayfish muscle fibre with intracellular recording, resting potential 78 mV. *A* and *B* in normal van Harreveld solution. *C*, molarity of van Harreveld solution increased by addition of 125 m*M* sucrose. Voltage calibration same for *A*, *B* and *C* ; 50 msec. calibration for *A*, 2 sec. for *B* and *C*

At vertebrate neuromuscular junctions the frequency of 'miniature end-plate potentials' is increased when the osmolarity of the extracellular fluid is raised[3]. This also applies to crustacean neuromuscular junctions. Thus in Fig. 1*C* a 50 per cent increase in osmolarity raised the frequency three times over that in Fig. 1*B*. Doubling the osmotic pressure resulted in a seven-fold rise in frequency. It seems unlikely that the spontaneous potentials arise from spontaneous conducted impulses in branches of the motor axon. Thus a five-fold increase in calcium concentration (to 67 m*M*/l., replacing sodium) prevented the appearance of an excitatory junctional potential following stimulation of the motor axon, but did not appreciably affect the spontaneous discharge. We could further exclude the release of inhibitory transmitter as the cause of spontaneous activity. When the membrane potential was shifted by passing current across the membrane the inhibitory junctional potential reversed its sign at the chloride equilibrium potential as previously seen by others[5]. The spontaneous activity, however, was not affected.

If the spontaneous potentials arise from transmitter released from excitatory nerve endings, one might expect the frequency of the discharge to be altered following stimulation of the excitatory nerve[6]. Fig. 2 shows that during the first second following a burst of excitatory junctional potentials at 100 per sec. for 1 sec. the frequency of the spontaneous potentials was increased; afterwards, however, the frequency was markedly decreased for a considerable period. If the duration of the excitatory stimulation was lengthened from 1 to 10 sec., only the decrease in frequency was observed for the entire 30-sec. interval between bursts of stimulations.

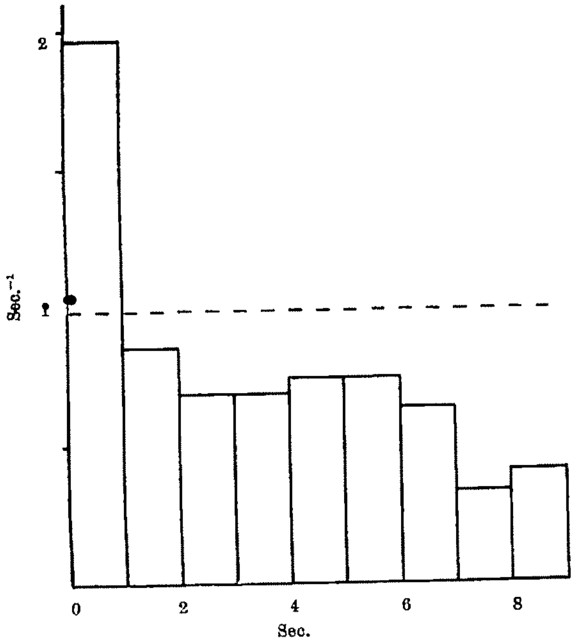

Fig. 2. Change in frequency of spontaneous potentials following stimulation of the motor axon. Abscissa: time after end of stimulation of excitatory axon at 100/sec for 1 sec., every 10 sec. Ordinate: number of spontaneous potentials observed per sec., average of 27 consecutive intervals between stimulations. The dotted line indicates the average frequency of spontaneous potentials at rest

All the observations are consistent with the assumption that the spontaneous potentials are analogous to 'miniature end-plate potentials' of vertebrates. However, until the chemical identity of the excitatory transmitter in these muscle fibres is known, more direct evidence that these potentials arise from the spontaneous release of transmitter from the nerve terminal will be difficult to obtain.

Spontaneous Potentials from Explants of Brain Tissue in Culture

SINCE July 1959 we have been recording spontaneous potentials from explants of brain in tissue culture. The tissue used was cerebellum from chick embryos of 8 days incubation and older. The supernatant was a 0·25 per cent solution of human serum protein in a physiologically balanced salt solution. The composition of the physiological balanced salt solution is as follows:

Potassium chloride	0·28	gm./litre
Sodium chloride	7·0	,,
Calcium chloride	0·28	,,
Magnesium sulphate	0·15	,,
Di-sodium hydrogen phosphate	0·08	,,
Di-potassium hydrogen phosphate	0·04	,,
Sodium bicarbonate	1·05	,,
Sodium acetate	0·05	,,
Dextrose	1·75	,,

The other techniques were those described in publications from this laboratory[1-3].

Spontaneous potentials have been obtained from cultures both in Kahn tubes and in flow systems as bursts of activity and as sustained activity from the time of explantation until another 14 days in culture. We have used a d.c. amplifier of our own design and a Dumont oscilloscope or Texas Instrument's 'Rectiriter'. The actual disturbance is illustrated in Fig. 1 and is composed of step-like combinations of positive and negative potentials lasting from a half to one and a half seconds each with a magnitude of up to 25 µV. Each culture had a simultaneous electrically inert control (dead brain tissue, pure epithelium cartilage or cornea without iris) with a repeated exchange of recording channel between control and brain tissue to exclude artefacts. We have been un-

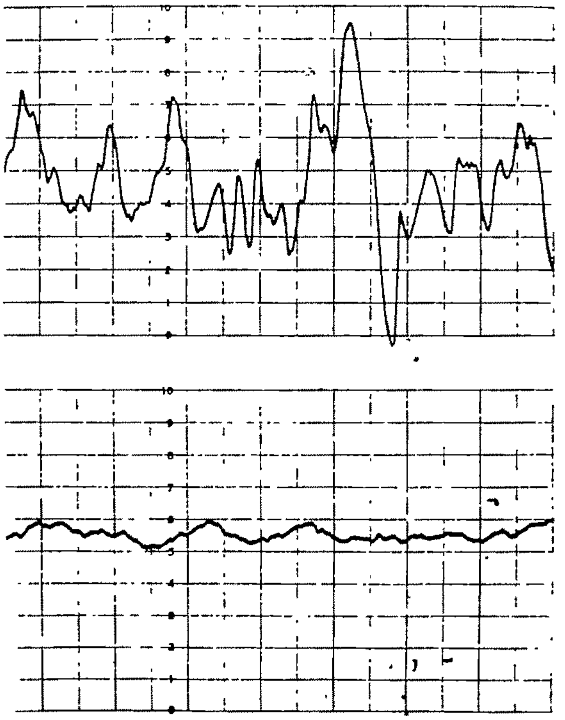

Fig. 1. Simultaneous dual-channel recording of spontaneous electrical activity from explants of chick embryo cerebellum in culture (upper channel) and control of dead brain tissue (lower channel). Full-scale vertical deflexion equals 25 µV. Time interval between each major horizontal division is 2·5 sec.

able to find any other record of spontaneous potentials from explants of brain tissue in culture.

Further investigations on these potentials are in progress.

This work was done under a U.S. Navy contract, *NONR* 1598 (04).

Activity of Muscle Receptors in the Kitten

In recent experiments[1] it was found that the tonic stretch reflex is lacking in the distal muscles of the limbs of the newly born kitten. Evidence was also presented that the gradual appearance of this reflex is due to a postnatal development of its afferent link, because its efferent link can easily be activated from other sources than stretch receptors at birth. The postnatal development of the afferent link is partly a maturation of the central connexions and functions of the muscle afferents[2-4], but as will be reported here it also consists of a development of the stretch receptors.

Whether or not the muscle spindles are functioning properly in the muscles lacking tonic stretch reflexes was, of course, one of the first questions asked. The study of these receptors in a newly born animal, however, met with great technical difficulties. Out of these has only to be mentioned that the fibre diameter of the largest afferents from, for example, the gastrocnemius muscle is about 2μ, making the isolation and recording from single functioning receptors extremely difficult. Recordings from a great many receptors have, however, been obtained by now allowing an evaluation of the experimental results.

The discharge of the stretch receptors in the gastrocnemius muscle has been studied both in dissected fibres of the dorsal roots *L* 7 and *S* 1 and in the muscle nerve. The ventral roots *L* 7 and *S* 1 were stimulated with square-wave shocks of 0·5 msec. duration given either singly or in a short tetanus. Muscle tension was recorded isometrically. The temperatures of the whole animal and of the muscle used were continuously controlled.

Recordings from the dorsal root of the muscle nerve of the discharge of the stretch receptors in the gastrocnemius muscle have shown that a sustained discharge in response to stretch is usually lacking in the newly born animal. When later present the frequency of the response is very low (Fig. 1*A* and Fig. 2) and soon adapts to zero. Repeated stretching of the muscle, however, gives rise to a response every time, as shown in Fig. 1*B*, even in the newly born animal. The lack of a sustained discharge makes a differentiation by behaviour during contraction between the responding receptors difficult. Intra-arterial injection of subparalytic doses of succinylcholine iodide, which is known to activate the muscle spindles selectively[5], sometimes makes the spindles fire continuously in the newly born animal, but always sensitizes them to respond with a few spikes on the falling phase of the contraction. By the use of this drug it was possible to differentiate between the responding receptors. It has thus been found that both muscle spindles and tendon organs in the gastrocnemius muscle of a newly born animal can be activated by stretch, but usually only phasically. It has constantly been found, however, that sustained discharges are obtained from proximally lying muscles around the hip and spine which usually are difficult to get rid of by denervation. In listening to the discharge of these receptors in the loudspeaker on stimulation of the ventral roots it can be heard that both spindles and tendon organs are present among the continuously firing receptors.

The muscles in the newly born kitten are known to have different properties from those in the adult animal[6]. It has here been found that they, besides having a slow contraction, are extremely plastic (see Fig. 2). The intrafusal fibres of the muscle spindles are known to grow out from extrafusal ones[7], and the plasticity could thus offer one explanation for the fast adaptation and inability of the muscle spindles to set up sustained discharges in response to stretch. If this was the only explanation, continually re-adjusting the tension to high values would set up sustained discharges. That has, however, not been found to be the case. The observation by Hursh[8], repeatedly confirmed during this investigation, that the absolute refractory period is twice as long as in the adult nerve before the developing fibres reach a conduction velocity of 18–20 m./sec., points to properties of the nerve fibres in the newly born animal that might prevent repetitive firing, at least with high frequencies.

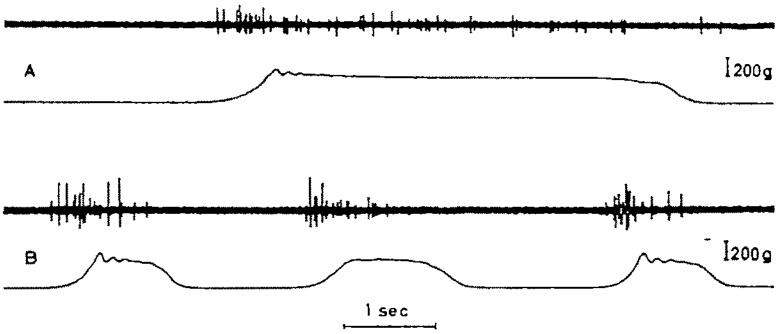

Fig. 1. The response of stretch receptors in the gastrocnemius muscle of a 3-day-old kitten recorded in a small twig of the medial nerve to the muscle during 8-mm. stretch

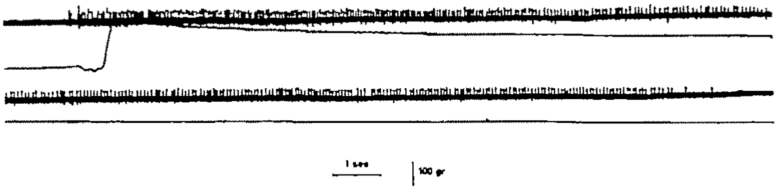

Fig. 2. The response of stretch receptors in the gastrocnemius muscle of a 10-day-old kitten to 12-mm. stretch, recorded in a fine filament of the dorsal root *S* 1. Note the fall in tension due to plasticity in the muscle, which is kept at constant length

A combination of immaturity of the sense organ with regard to mechanical properties and of the afferent fibre with regard to excitability (not necessarily a function of its diameter which is but a good correlative measure) explains the adaptation and the inability to respond to both high tensions and succinylcholine iodide with sustained discharges respectively. In conformity with this, it has been found that the stretch receptors usually fire continuously when the conduction velocity of the afferents has reached 18–20 m./sec., which happens 8–10 days postnatally, but as can be imagined from Fig. 2 adaptation due to plasticity will still play a great part in small extensions.

In trying to find out when the gamma-efferents start activating the muscle spindle, it was found that stimulation slightly above threshold for the alpha-fibres often activated a few spikes during the early phase of a muscle contraction. This is thought to be an alpha-activation of the spindle[9] which appears earlier postnatally than the well-known gamma-excitation, which is obtained 18–20 days postnatally.

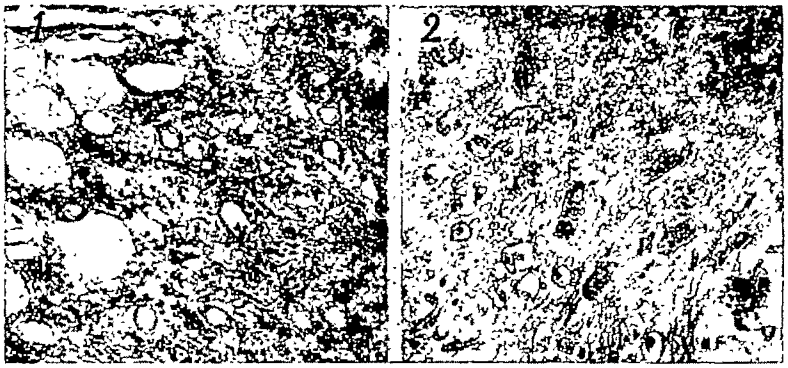
Histochemical Demonstration of Ascorbic Acid in the Locus Coeruleus of the Mammalian Brain

Diehl and Neumann[1] have determined the content of ascorbic acid in the various portions of the human brain and found a characteristically high content in the autonomic centres (tuber cinereum and medulla oblongata). By means of the histochemical method the neurosecretory nuclei of the hypothalamus were reported to contain many silver granules due to reduction of silver nitrate by ascorbic acid[2–4]. Although in the above chemical and histochemical reports particular attention was not paid to the locus coeruleus, the locus was recently found by a histochemical method (Shimizu *et al.*[5,6]) to demonstrate the pronounced activity of monoamine oxidase, and by several physiological investigations[7–9] to regulate respiration, as the pneumotaxic centres. As the locus coeruleus was thus supposed to display some autonomic (visceral) functions, which might be related to amine metabolism, we thought it reasonable to search for the histochemical presence of ascorbic acid in the locus coeruleus.



Figs. 1 and 2. Distribution of ascorbic acid in the brain, stained by the Giroud and Leblond method. The silver granules are due to a reduction of acidified silver nitrate by ascorbic acid. Fig. 1. Locus coeruleus of rat. A large amount of silver granules is demonstrated mainly within the nerve cells of the locus coeruleus. Several large nerve cells of the mesencephalic nucleus of the trigeminal nerve (at the left hand of the figure) are essentially devoid of silver granules (× c. 330). Fig. 2. Locus coeruleus of guinea pig. Moderate amounts of silver granules are encountered in several nerve cells of the locus coeruleus (× c. 330)

Experimental animals used consisted of healthy adult mice, rats and guinea pigs and also scorbutic guinea pigs. Thin slices of the brain were fixed in the acidified silver nitrate solution for 30 min. according to Giroud and Leblond's method (cf. Gomori[10], and Lison[11]) following intravascular perfusion first with an isotonic fructose solution and then the silver nitrate solution.

In the brain of the normal animals tested silver granules due to the presence of ascorbic acid occurred most abundantly in mice, intermediately in rats and least of all in guinea pigs. In mice and rats large amounts of silver granules were demonstrated constantly in the locus coeruleus (Fig. 1), where the silver granules were mainly encountered within the nerve cell bodies. The same observation was also made in the paraventricular and supra-optic nuclei of the hypothalamus as other investigators[2–4] already reported. Similar but less evident deposition of silver granules was further revealed in the dorsal nucleus of the vagus nerve and area postrema of mice. Regions of the brain other than the above nuclei showed rather irregular deposition of silver granules, which were present in small (rats) or moderate amounts (mice). For example, varying amounts of silver granules were found in the nerve-cell bodies of the cerebral and cerebellar cortices.

The brains of normal healthy guinea pigs showed the deposition of silver granules much less clearly than those of rats and mice and the silver granules were demonstrable exclusively in limited portions of the brain in contrast to the observation in rats and mice. Moderate amounts of silver granules (Fig. 2) were shown in the nerve cell-bodies of the locus coeruleus as well as in those of the paraventricular nucleus. Small numbers of the granules were present, furthermore, in the supra-optic nucleus, dorsal nucleus of the vagus nerve and area postrema. These silver granules were completely abolished in the scorbutic guinea pigs, which were fed on the vitamin C deficient diet for about twenty days. This observation indicates that the deposition of silver granules in the above nuclei might be due to the presence of ascorbic acid.

Our observations that ascorbic acid is concentrated in the locus coeruleus, dorsal nucleus of the vagus nerve and area postrema as well as in the hypothalamus lead us to suppose that this vitamin might be implicated in the metabolism of the autonomic centres of the brain. Ascorbic acid is said to be required for the oxidation of tyrosine and in this process it does not seem to act as a specific cofactor and its role is probably that of a reducing agent (cf. Mehler[12], Fruton *et al.*[13]). Co-existence of ascorbic acid with monoamine oxidase might constitute a suitable condition for the active aromatic amine metabolism in these nuclei.

Serotonin Content of the Pineal Glands of Man and Monkey

GIARMAN *et al.* have demonstrated the presence of certain neurohumours and some of their associated enzymes in the bovine pineal gland[1,2]. While determining the relative distribution of serotonin in specific areas of human brain, we have obtained the pineal glands of deceased mental patients. The glands were removed within 24 hr. *post mortem*, and kept at the temperature of dry ice, usually for 24 hr., when extraction of serotonin was carried out. Only minimal losses are encountered with such a procedure. The pineals were homogenized with 2 ml. of isotonic salt solution and the amine extracted with 95 per cent acetone by a modification of the method of Amin, Crawford and Gaddum[3]. Estimation of the content of serotonin in the extracts was made by assay on the heart of *Venus mercenaria*[4]. For purposes of comparison freshly excised pineal glands from non-psychotic deceased patients and from 17 rhesus monkeys were treated and assayed in the same manner. Table 1 summarizes the results presented here and includes some values obtained previously[2] from freshly excised and fresh-frozen bovine glands.

It is clear that the pineal gland of both man and monkey is considerably richer in serotonin than that of the cow. In fact, the serotonin-levels found in the majority of human and simian glands are the highest ever reported for any neural structure of any species examined. These values approach the levels found in the spleen and portions of the gastro-intestinal tract. Moreover, pretreatment with the monoamine oxidase inhibitor, iproniazid ('Marsilid'), fails to give values in this range either in whole rat's brain[5] or in specific areas of the dog's brain[6]. Our study of other regions of the human brain has shown high values of 0·48 γ/gm. in the central grey of the midbrain and 0·43 γ/gm. in the reticulum of the medulla oblongata (Freedman, D. X., Picard-Ami, L., and Giarman, N. J., unpublished work). Costa and Aprison have reported high values of 0·5–1·0 γ/gm., which they found in mesencephalic and diencephalic structures of the human brain[7].

Table 1 SEROTONIN IN HUMAN, SIMIAN AND BOVINE PINEAL GLANDS

Species	Age	Diagnosis	Weight of pineals (gm.)	Serotonin content (γ/gm.)
Human male	89	Cerebral arterio-sclerosis	0·120	1·00
Human male	76	Manic depressive	1·890	0·36
Human female	78	Chronic schizophrenic	0·450	10·60
Human male	84	Senile brain disease	0·480	5·33
Human male	37	Schizophrenic reaction, chronic	0·305	0·59
Human male	40	Schizophrenic reaction, chronic	0·285	1·54
Human male	90	Chronic brain syndrome	0·115	2·08
Human male	45	Chronic brain syndrome; also delirium tremens	0·210	22·82
Human female	44	Cirrhosis of liver	0·130	5·77
Human male	86	Bronchogenic carcinoma	0·095	2·63
Human male	74	Myocardial infarct.	0·110	2·18
17 Rhesus monkeys (adult male)			Mean Range	3·28 1·20–10·00
13 Steers			Mean Range	0·40 0·20–0·63

The greatest variability of serotonin content was found in the human pineal gland, with values ranging from 0·36 γ/gm. to 22·82 γ/gm. (see Table 1). While these human glands (especially those from psychotic patients) showed great variation in weight, there was clearly no correlation between weight and serotonin content. In contrast, the serotonin content of the bovine pineal glands fell within the relatively narrow range of 0·20 γ/gm.–0·63 γ/gm., and their weight was an almost uniform 0·20 gm. The variability in the serotonin content of the simian glands fell between that of the human and that of the bovine glands. It was established in control experiments that the prior ingestion of bananas failed to correlate with elevated serotonin-levels found in the simian pineal glands.

The seemingly greater variability of values in the glands taken from patients with psychiatric disorders than in those from the three representatives of the 'normal' population cannot be interpreted because of the small sample and wide range of diagnoses represented. Any apparent trend requires replication of studies from selected diagnostic categories and investigation, among other factors, of histology and of relative monoamine oxidase activities. One inference we might currently make refers to the apparent unrelatedness of serotonin content of the human pineal to age in the group 35–90 years of age.

Despite a long-standing philosophical and scientific interest in the pineal gland and a large number of somewhat sporadic investigations[8] the function of the pineal and the relation of this function to its chemistry or pathology are still unknown. Similarly, any proposed relationship of the pineal gland and mental function[9] lacks confirmation by other investigators. On the other hand, possible inter-relationships of the pineal with the adrenal cortex, gonads, and the pituitary gland have been reported. Farrell *et al.*[10] noted that destruction of the pineal region reduced secretion of aldosterone by the adrenal cortex, while infusion of bovine pineal extract restored such secretion to normal (Farrell, G., unpublished results sent in personal communication from E. S. Redgate).

Lerner *et al.*[11] have isolated a skin-lightening hormone, melatonin, from the bovine pineal gland, and found it to antagonize the skin-darkening effect of melanocyte-stimulating hormone, secreted by the neurohypophysis. Wurtman *et al.*[12] reported that pinealectomy in young female rats led to pituitary and gonadal hypertrophy, which was reversible by injection of pineal extract. These findings and our earlier reports[1,2] on the presence of neurohumours and associated enzymes in the bovine pineal gland tend to support the view that the pineal satisfies certain criteria for physiological function, and further investigation into the nature of this function is necessary.

This research was aided in part by grant *B*940 from the National Institute of Neurological Diseases and Blindness and in part by grant *M*-1204 from the National Institutes of Mental Health. We are indebted to Dr. D. Howie, pathologist at the Fairfield State Hospital, for autopsy material, and to Dr. V. L. Loosanoff, U.S. Fish and Wildlife Service, Milford, Conn., for supplying us with the *Venus mercenaria*.

HÆMATOLOGY

Evidence for a New Allele in the Kidd Blood Group System in Indians of Northern Mato Grosso, Brazil

A NEW phenotype in the Kidd blood group system, *Jk* (*a–b–*), has recently been recognized in a Filipina of Spanish and Chinese ancestry[1]. This phenotype is extremely rare in Whites and Negroes; its incidence in Asian people or their descendants has not as yet been determined. We recently had the opportunity to study the blood groups of a number of Brazilian Indians indigenous to the northern part of Mato Grosso in the region of the headwaters of the Upper Xingu River. Because of the peculiar geographical features defining this area, these Indians live in virtual isolation, and because of tribal customs, marriage is exclusively between first cousins. The present communication reports the frequency of the phenotype *Jk* (*a–b–*) and evidence for a new allele, *Jk*, in a sample of this population.

Venepuncture specimens were collected in sterile vacuum tubes containing acid–citrate–dextrose solution, and shipped by air to New York, where the testing was performed 3–5 weeks after the initial collection. It was possible to obtain 88 specimens from representatives of four linguistic groups. The names of these groups and the distribution of the phenotypes of the Kidd system are shown in Table 1. Because of the heretofore reported rarity of the phenotype *Jk* (*a–b–*), detailed re-testing was performed on the five specimens found to be *Jk* (*a–b–*). The cells were tested with three different anti-Jk^a sera, two anti-Jk^b sera, and with the serum of Mrs. Santos, the patient reported by Pinkerton *et al.*[1]. In all instances negative results were obtained.

Table 1. DISTRIBUTION OF PHENOTYPES OF THE KIDD BLOOD GROUP SYSTEM IN 88 INDIANS OF MATO GROSSO

Name of tribe	Number tested	Phenotypes			
		Jk ($a-b-$)	*Jk* ($a+b-$)	*Jk* ($a-b+$)	*Jk* ($a+b+$)
Carib	13	2	7	2	2
Arawak	19	0	4	7	8
Tupi	43	1	19	10	13
Trumai	13	2	4	6	1
Total	88	5	34	25	24

Calculations of gene frequencies based upon the hypothesis that only two alleles exist in the Kidd system yielded results that were internally inconsistent. The results were then recalculated on the assumption that three alleles exist, using Bernstein's method as described by Mourant[2]. The agreement between the observed and theoretical frequencies shown in Table 2 provides further evidence for the presence of a third gene, *Jk*, in the Kidd blood group system. It appears likely that this gene, though rare in Caucasians, is common in Asians and their descendants.

Table 2. PHENOTYPE AND GENE FREQUENCIES

	Phenotypes (per cent)				Genes (per cent)

Role of C'_4 in the Antiglobulin Reaction

WHEN human red cells are incubated with fresh serum containing a complement-binding blood-group antibody, they become agglutinable by an anti-'non-γ' globulin serum, that is, a serum reacting with human globulins other than γ-globulin[1-3]. In such cases the antiglobulin serum reacts with complement (C') rather than with the blood-group antibody[4].

The object of the present work was to identify more precisely the antigen and antibody concerned in this reaction: that is, the particular component of C' on one hand and the particular antiglobulin on the other.

In trying to identify the component of C' reacting with antiglobulin serum, two approaches were used. First, red cells sensitized with antibody were allowed to react with C' under conditions which permitted the formation of the complex $C'_{1,4}$ but were unfavourable to the formation of $C'_{1,4,2}$ [5,6]. Secondly, sensitized red cells were treated with some components of C' supplied from human serum and other components supplied from rabbit serum. In both sets of experiments the cells were tested with antiglobulin serum (either with anti-human globulin or anti-rabbit globulin), and with immuno-conglutinin serum (I—K) of the type described by Coombs and Coombs[7] as "I—K serum (auto-stimulation)".

In the first series of experiments, sensitized red cells (for example, $Le(a+)$ red cells incubated with inactivated anti-Le^a) were treated with de-ionized serum to which either calcium or calcium and magnesium had been added. Gandini[8] has recently published the results of similar experiments. Like Gandini we found that sensitized red cells treated at 0° C. with fresh serum containing calcium but not magnesium would react with antiglobulin serum, suggesting that the adsorption of C'_2 is not necessary for a positive antiglobulin reaction. We also carried out experiments at 37° C. and found that cells treated with de-ionized serum to which only calcium had been added reacted moderately strongly with an antiglobulin serum and weakly with an I—K serum (the positive reaction of the I—K serum could be explained by the presence of small amounts of magnesium in de-ionized serum[5]). Sensitized cells treated with serum to which calcium and magnesium had been added reacted strongly with I—K serum, but the reaction with an antiglobulin serum was also improved. This enhancement of the antiglobulin reaction suggested either that the adsorption of C'_2 enhances the adsorption of C'_4 or that C'_2 itself reacts with the antiglobulin serum. In an attempt to decide between these hypotheses, a second series of experiments was done.

For these experiments preparations containing predominantly C'_1 or C'_2 were made from human serum and rabbit serum by the method of Pillemer *et al.*[9]. Human serum containing only C'_4 was prepared by heating fresh serum to 56° C. for 30 min. and then treating it with zymosan. Rabbit serum was heated only to 52° C. for 30 min. because at higher temperatures C'_4 was destroyed; the serum was not treated with zymosan since this removes all complement activity[10].

Sensitized red cells incubated with human C'_1 alone were not agglutinated by an anti-human globulin serum; but if they were first incubated with human C'_1 or rabbit C'_1 and then incubated with human C'_4, they were agglutinated by anti-human globulin serum. Similarly, sensitized cells treated with human C'_1, then with rabbit C'_4 (and C'_3), were agglutinated by anti-rabbit globulin serum.

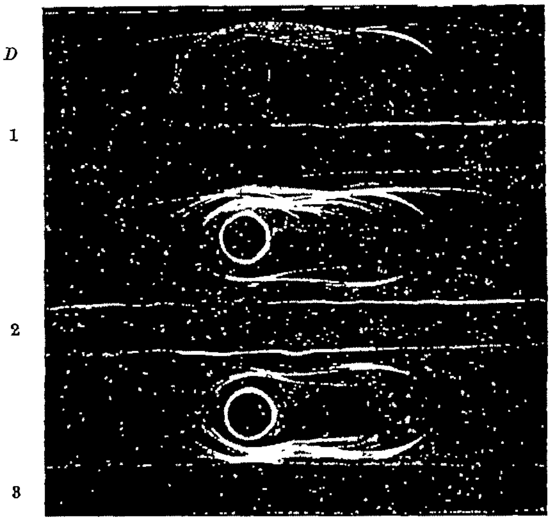

Fig. 1. Immuno-electrophoresis of normal human serum (placed in the circular cups and submitted to electrophoresis) versus anti-human globulin serum (in the longitudinal troughs 1, 2 and 3). The anti-human globulin serum was a specially selected one which only contained antibodies against α- and β-globulins (the line extending farthest to the left in the figures is due to β_2-globulin). 1, The untreated antiglobulin serum; 2, the same antiglobulin serum absorbed with 'complement-coated' cells, that is, sensitized red cells treated with human complement; 3, the same antiglobulin serum after absorption with sensitized red cells not treated with human complement; *D*, diagram of the reactions of the unabsorbed antiglobulin serum; the lines in the β_1-globulin region removed by absorption with 'complement-coated' cells are indicated by broken lines

In the case in which cells were first exposed to rabbit C'_1, then to heated, zymosan-treated, human serum, it seems clear that the only component of human complement adsorbed was C'_4, and since the cells were strongly agglutinated by anti-human globulin serum, C'_4 must be the chief and perhaps the only protein reacting with the antiglobulin serum. Nevertheless, stronger reactions with anti-human globulin serum were obtained when sensitized red cells were treated with rabbit C'_1 and C'_2 and human C'_4 than when they were treated with only rabbit C'_1 and human C'_4, so that again there is suggestive evidence that C'_2 enhances the adsorption of C'_4.

The conclusion that antiglobulin serum does not react directly with C'_1 is supported by the further observation that when sensitized red cells were incubated with fresh serum and then treated for 1 hr. at 37° C. with 0·01 M ethylenediamine tetra-acetic acid (treatment which is said[11] to remove virtually all C'_1 from the cells without removing C'_4), the cells still reacted strongly with antiglobulin serum.

That antiglobulin serum and I—K serum do not detect complement in the same state is known from the fact that the reactions of antiglobulin serum, but not I—K serum, are inhibited by the addition of whole serum to the reagent. A further difference may be shown by incubating sensitized cells with C' for varying periods, for after 4–5 hr. the cells no longer react with I—K serum but still react strongly with antiglobulin serum[10]; similar observations have been reported by Gandini[8]. Coombs *et al.*[12] and Gandini[8] have shown that C'_1, C'_4 and C'_2 are all needed for a positive I—K reaction. Incidentally, we have noted that in tests with an I—K serum it is common to observe that only a proportion of the cells are agglutinated, the appearance being that of a mixture of strongly agglutinated cells and unagglutinated cells; this may be due to the fact that the complex $C'_{1,4,2}$ decays rapidly at 37° C.[13] so that only a proportion of the cells are 'coated' with the active complex.

In order to identify the antibody in the antiglobulin serum reacting with C' adsorbed on to red cells, antiglobulin sera were examined by the technique of immuno-electrophoresis, before and after absorption with 'complement-coated' cells. Sheep red cells were sensitized with bovine antibody and then incubated with fresh human serum (previously absorbed with unsensitized sheep red cells). These 'complement-coated' cells, after being well washed, were used to absorb several different anti-human globulin sera. The sera were absorbed until they no longer agglutinated red cells which had adsorbed human C'. Such absorbed sera were found to have lost lines in the β_1 region (Fig. 1). This finding is consistent with the observation of Ellis and Gell[14], who immunized rabbits with an antigen–antibody precipitate which had been allowed to adsorb human C' and obtained a serum containing predominantly an anti-β globulin; and of Matuhasi and Usui[15], who obtained anti-β_1 and anti-α_2 following the injection of human C' adsorbed on to an antigen–antibody complex.

The conclusion of Gandini[8] that the antibody reacting with adsorbed complement is anti-α_2 may have been due to the fact that the particular preparation of α_2-globulin which he used is known to contain traces of other globulins (unpublished observations). We have found that a very pure preparation of 19*S* globulin, kindly prepared by Dr. R. A. Kekwick, containing only α_2- and γ-globulin fails completely to inhibit the reaction between antiglobulin serum and 'complement-coated' cells. On the other hand, we have succeeded in inhibiting the reaction by adding a fraction of serum containing predominantly β_1-globulin, obtained from starch-block electrophoresis.

It appears, then, that the so-called 'non-gamma globulin' Coombs reaction is a reaction between C'_4 adsorbed on to red cells and a corresponding anti-β_1 globulin.

Further Evidence for the Dual Nature of the Third Component of Complement

DURING the past two years there have been several reports of the complex nature of the third component of complement ($C'3$) based on its lysis of sensitized erythrocytes in the presence of the other components of complement[1–3], and Rapp *et al.*[4] have separated two factors from guinea pig serum which are both needed for the action that was previously associated with $C'3$. The existence of two such factors has also been suggested by the experiments described here.

Guinea pig serum heated to 56° for 20–30 min. fails to lyse sensitized erythrocytes that have already reacted with the first, second and fourth components of complement ($EAC'_{1,4,2}$) (see Table 1). This is not due to an anti-complementary action of heated serum, since it will not inhibit the lysis of $EAC'_{1,4,2}$ by whole guinea pig serum in the presence of 0·02 *M* versene. Classical methods of titrating $C'3$[5] using an $R3$ (whole serum from which $C'3$ has been removed by treatment with zymosan) indicated that only about 50 per cent of the $C'3$ in guinea pig serum is inactivated by heating, so that heated serum should be able to bring about the lysis of $EAC'_{1,4,2}$ unless some previously unknown heat-labile factor is also involved. Definite evidence for this factor was obtained by treating $EAC'_{1,4,2}$ (prepared according to the directions of Levine *et al.*[6]) for 15 min. at 37° with heated serum, centrifuging, resuspending the cells in $R3$, incubating for a further 15 min. at 37° and then determining the percentage hæmolysis. Table 1 shows that this leads to considerable hæmolysis, while treating $EAC'_{1,4,2}$ with the two reagents in the reverse order gives practically no hæmolysis.

Table 1. HÆMOLYSIS OF $EAC'_{1,4,2}$ BY GUINEA PIG SERUM REAGENTS

Reagent (in order of reaction with $EAC'_{1,4,2}$)	Percentage of hæmolysis of $EAC'_{1,4,2}$ prepared with. guinea pig serum	human serum
Heated serum + $R3$	43	37
$R3$ + heated serum	7	12
Heated serum alone	5	7
$R3$ alone	15	17
Serum + 0 02 *M* versene*	51	—
Serum + 0 02 *M* versene + heated serum*	52	—

* Reacted simultaneously with $EAC'_{1,4,2}$

Similar results are obtained by treating $EAC'_{1,4,2}$ prepared with human serum as a source of complement by the method of Leon[7] with the two reagents from guinea pig serum. However, the analogous reagents prepared from human serum will not lyse $EAC'_{1,4,2}$ prepared with either human or guinea pig serum. $R3$ from human serum can replace $R3$ from guinea pig serum, but heated human serum cannot substitute for heated guinea pig serum in these systems.

It is suggested that the term $C'3$ should be reserved for the component of complement that is adsorbed by zymosan and is comparatively heat-stable, while the new heat-labile factor not adsorbed by zymosan which reacts last in the known series of complement components should be called the fifth component of complement ($C'5$). Work on the identification of these components with Rapp's factors *a* and *b*[4] is proceeding.

Preliminary investigations of the kinetics of the reactions of $C'3$ with $EAC'_{1,4,2}$ and of $C'5$ with $EAC'_{1,4,2,3}$ suggest that the first reaction is a fast one and the complex $EAC'_{1,4,2,3}$ loses its reactivity with $C'5$ fairly rapidly at 37°, while the second reaction involving $C'5$ and leading to hæmolysis is a comparatively slow one. This is in apparent conflict with Rapp's demonstration of a short lag in the hæmolysis of $EAC'_{1,4,2}$ by versene-treated guinea pig serum[1] (containing $C'3$ and $C'5$), which suggests that the earlier step is rate limiting. This discrepancy would be resolved if the reaction of $C'5$ with the complex $EAC'_{1,4,2,3}$ could be shown[7] to be slower than the lytic reaction of the sensitized erythrocyte which has already reacted with all five components of complement.

The helpful and stimulating interest of Prof. A. Wormall is most gratefully acknowledged.

Hæmoglobin Content of the Larvæ of *Tendipes f.l. plumosus* L. from Various Levels of Bed Sediment

In previous work[1,2] it was shown that the amount of hæmoglobin in the larvæ of *Tendipes f.l. plumosus* varies according to the amount of dissolved oxygen present. However, the results obtained cannot be considered to be particularly reliable since at various seasons the larvæ are at various stages of development, and this may have some effect on the hæmoglobin content.

In order, therefore, to prove that the amount of hæmoglobin depends on the oxygen content of the environment, I tested for hæmoglobin content larvæ from various levels of bed sediment at the same period, taking into consideration the age of the larvæ. If the amount of dissolved oxygen is larger in larvæ from the surface layer, in which oxygen content is without doubt greater than in the deeper layers, then the amount of hæmoglobin should be less in larvæ from that layer than in larvæ from deeper layers.

Tendipes f.l. plumosus larvæ were collected for analysis from the bed of the Ordynacki pond in Dojlidy (a suburb of Białystok). Specimens were taken on the day when the pond had been emptied; thus it was possible to collect them and to calculate the exact depth of the strata from which they were taken. The larvæ were collected from two layers: from a 6-cm. surface layer and from a layer 10 cm. below it. The hæmoglobin content was determined by the method used in the previous studies[3]. The age of the larvæ was estimated by measuring the size of their heads[4].

Table 1. Hæmoglobin Content in the Larvæ of *Tendipes f.l. plumosus* L. from Different Layers of Sediment on the Bed of the Ordynacki Pond. Dry Mass (per cent)

Position No.	Surface layer (6 cm. deep)	Layer 10 cm. deeper
1	8·2	27·5
2	8·0	28·3
3	3·1	28·0
4	10·1	26·5
5	11·6	28·3
Average	8·2	26·7

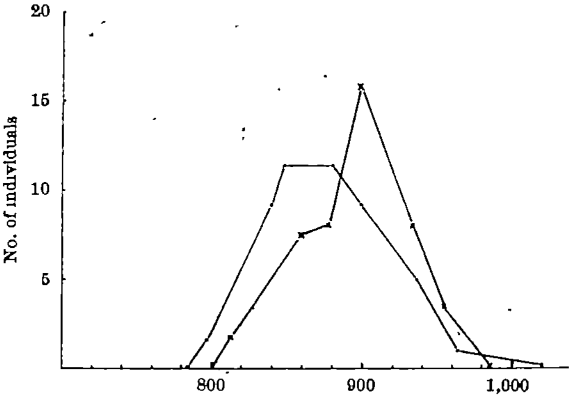

Fig. 1. Size of head of the larvæ of *Tendipes f.l. plumosus* L. .—.—.—, Surface layer (6 cm.); ×—×—, layer 10 cm. deeper

As a result of these studies it was found that the larvæ of *Tendipes f.l. plumosus* from the 6-cm. surface layer and those from the layer 10 cm. deeper were in the fourth stage of development (Fig. 1), despite the fact that the body measurements and weight of dry mass of one larva from the deeper layer are greater[5]. As will be seen from Table 1 there is a difference in the amount of hæmoglobin found in larvæ from the two layers of bed sediment. In the superficial layer the hæmoglobin content averaged 8·2 per cent of dry mass, whereas in the deeper layer of 10 cm. the hæmoglobin content of the larvæ varied, the average being 26·7 per cent. There is no doubt but that in the 6-cm. surface layer the oxygen content is much greater than that of the deeper layer. The fact that there is more hæmoglobin in the larvæ from the deeper layer is due to the smaller amount of oxygen there. It is characteristic that in that part of Rajgrodzkie Lake where there is least oxygen, not only is the hæmoglobin content highest and the weight of one of the larvæ heaviest but also that there is a greater concentration of larvæ found at that depth[6].

RADIOBIOLOGY

Removal of Strontium from Milk

The importance of milk as a dietary source of calcium and other important nutrients makes it desirable to develop methods for use in removing radiostrontium from milk in the event that the concentration of the radioisotopes of strontium in this food should become a health hazard. Migicovsky[1] has

Table 1. EFFECT OF BONE COLUMN TREATMENT ON REMOVAL OF STRONTIUM-85 AND COMPOSITION OF MILK. (COLUMNS APPROXIMATELY 12–14 CM. × 1·8 CM.)

Bone	Amount bone (gm.) per quart milk	Calcium (m.equiv./l.)	Sodium (m.equiv./l.)	Potassium (m.equiv./l.)	Phosphorus (mgm. per cent)	Strontium-85 removed (per cent)
Control milk		55	24	39	88	
Anorganic bone treated with 4 *N* calcium chloride	25	51	21	37	89	57
Fat-free bone treated with 8 *N* potassium hydroxide	33	34	21	38	71	75
Fat-free bone treated with 4 *N* calcium chloride and 8 *N* potassium hydroxide	33	34	21	37	60	70

employed a synthetic resin in the mixed calcium, potassium, and sodium forms to remove substantial amounts of the radioisotopes of strontium and cæsium from contaminated milk. A large amount of resin to the volume of milk treated is required by this method.

Bone, owing to the fact that it contains as its mineral phase crystals of apatite, rapidly sequesters strontium ions from fluids *in vivo* and *in vitro*[2]. This property of bone has been utilized to develop a simple process for the removal of radiostrontium from milk. Various methods used in preparing bone for use have been observed markedly to affect the efficiency of the material in taking up strontium. The following have been found to be more effective than other forms of apatites: anorganic bone prepared by removal of proteins by extraction of bone with ethylene diamine[3]; fat-free bone prepared by extraction of lipids with a 50 per cent mixture of alcohol and ether; anorganic bone or fat-free bone treated with 4 *N* calcium chloride solution and the same materials treated with 4 *N* calcium chloride solution followed by 8 *N* potassium hydroxide solution. Excesses of each of the latter solutions were removed by washing the solids with water. Table 1 presents data demonstrating the efficiency of columns of pulverized modified bone (40–60 mesh) in the removal of strontium-85 added to milk. Analyses of milk before and after treatment are also given. Anorganic bone treatment produces the least alteration in milk composition and appears efficient in the removal of added strontium-85. Fat-free bone further modified, as indicated in Table 1, also has a marked ability to remove radiostrontium from milk but produces more alteration in the ionic composition of milk than anorganic bone.

10 ml. of 4 *N* calcium chloride solution will remove the bulk of the radiostrontium picked up by 10 grams of bone from milk. Potassium hydroxide does not improve the regeneration of anorganic bone column treated with calcium chloride, but it almost doubles the regeneration of a fat-free bone previously treated with calcium chloride.

The effect of treating fat-free bone with potassium hydroxide and/or calcium chloride on the efficiency of a column in removing strontium-85 added to a quart of milk is shown in Table 2. In each trial a constant flow-rate of 2 ml. per min. was maintained. As indicated a single column of modified fat-free bone can be regenerated repeatedly and is most efficient after combined treatment with calcium chloride and potassium hydroxide solutions. Anorganic bone can be repeatedly reactivated and re-used after calcium chloride treatment alone. The calcium content of milk when altered can be re-adjusted, if desired, by calcium additives. A taste panel has not reported changes in flavour of the treated milk. Greater efficiency in removal of radiostrontium by these materials should be obtained with longer columns.

Table 2. REMOVAL OF ADDED STRONTIUM-85 FROM MILK WITH A REGENERATED FAT-FREE BONE COLUMN (15 CM × 1 CM. DIMENSIONS)

Trial	Column* treatment	Percentage activity removed from milk (per quart)
1	8 *N* Potassium hydroxide	34
2	4 *N* Calcium chloride	23
3	4 *N* Calcium chloride 8 *N* Potassium hydroxide	47
4	4 *N* Calcium chloride 8 *N* Potassium hydroxide	45
5	4 *N* Calcium chloride	25
6	4 *N* Calcium chloride 8 *N* Potassium hydroxide	39

* 50 ml. of regenerating solution per trial.

It has been demonstrated in other experiments in which a gram of solid was mixed for 10 min. with 50 ml. of milk that approximately 50 per cent of the radiostrontium was removed by fat-free bone pre-treated with potassium hydroxide or by anorganic bone.

The techniques described indicate that a simple method for the commercial treatment of milk based upon these results is practical.

Effect of Oxygen on the Radiosensitivity of Bacteriophage in the Presence of Sulphydryl Compounds

IONIZING radiation is generally more effective in killing cells if oxygen is present at the time of irradiation[1]. In view of the variety of the organisms in which the injury appears to be associated with the genetic apparatus[2], it is surprising that no oxygen effect should be found when bacteriophage[3] and transforming principle[4] are irradiated in an aqueous suspension containing nutrient broth or other material to protect them against indirect radiation effects.

The suggestion that a hydrogen donor may be responsible for the reduced sensitivity found under anoxia has been put forward on chemical grounds[5], and a similar conclusion has been reached from an analysis of the kinetics of the effects of oxygen and nitric oxide on the radiosensitivity of bacteria[6]; but direct evidence in support of the role of a hydrogen donor in the oxygen effect in a biological system has been lacking.

Two observations have directed attention to the sulphydryl compounds in this connexion. Cysteine[7] and cysteamine[8] gave added protection to *T*2 bacteriophage, which appeared to be already fully protected by nutrient broth. In an attempt to elucidate this effect, an investigation has been made into the effect of known concentrations of oxygen and cysteamine on the radiosensitivity of bacteriophage protected from indirect action. Similar experiments have been carried out with the *T*2 *E. coli B* complex formed by the adsorption of *T*2 to the host cell.

Wild-type *T*2 bacteriophage were irradiated in aqueous suspension, diluted in nutrient broth, plated in a layer of soft agar seeded with *E. coli B* and incubated at 37° C. It was found that thiourea was more effective than nutrient broth in protecting the phage against indirect effects of irradiation, and was convenient in that it did not froth when bubbled with a gas. Thiourea was without toxic effect even at high concentration, so long as it was adequately diluted before plating. The complexes were prepared from a logarithmic phase culture of *E. coli B* which was infected at a multiplicity of about 0·02 phage per bacterium in the presence of cyanide. Phage which had not adsorbed were inactivated with antiserum. The irradiations were carried out at 30,000 rads per min. with 8-MeV. β-rays at 2° C. As both cysteine and cysteamine oxidize at *p*H 7, care was taken to see that the oxidation to the disulphide form and the resulting depletion of oxygen did not influence the results of the experiment. Samples of the suspension were placed in an irradiation vessel which had a glass filter base. To control the amount of oxygen present, either oxygen or oxygen-free nitrogen was passed through the filter so that it bubbled through the suspension. Thus anoxia was ensured by the nitrogen stream, independently of the presence of the sulphydryl compound. When oxygen was bubbled through the suspension containing cysteamine, some oxidation occurred. At the end of the irradiation, after bubbling with oxygen for a total period of about 10 min., the amount of —SH remaining was found to be more than 80 per cent of the initial concentration, as estimated by the nitroprusside method[9]. Studies of the rate of equilibration of the dissolved gases in a similar bubbling vessel indicated that the concentration of oxygen fell by a factor of 100 in 40 sec. when nitrogen was bubbled through a suspension containing oxygen. It was estimated that at this rate of equilibration, the amount of oxygen consumed in the oxidation of the cysteamine would reduce the oxygen concentration by less than 10 per cent below the equilibrium value of 2 m*M*. Thus, during the period of the irradiation, the concentration both of cysteamine and oxygen was known to lie within certain limits.

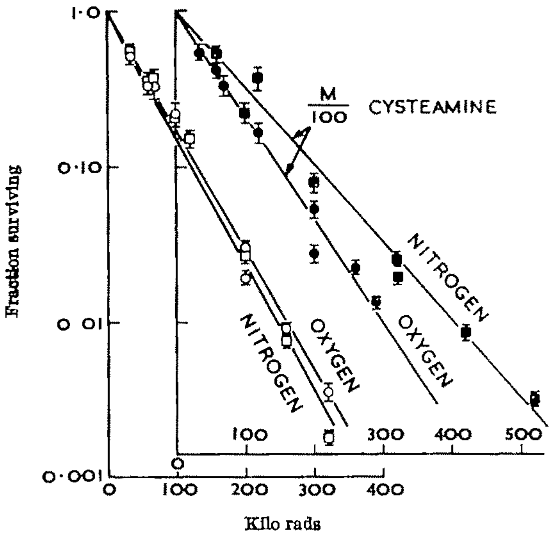

Fig. 1. Effects of 10 m*M* cysteamine and 2 m*M* oxygen on the inactivation of *T*2 phage suspended in buffer at *p*H 7 with 10 m*M* thiourea

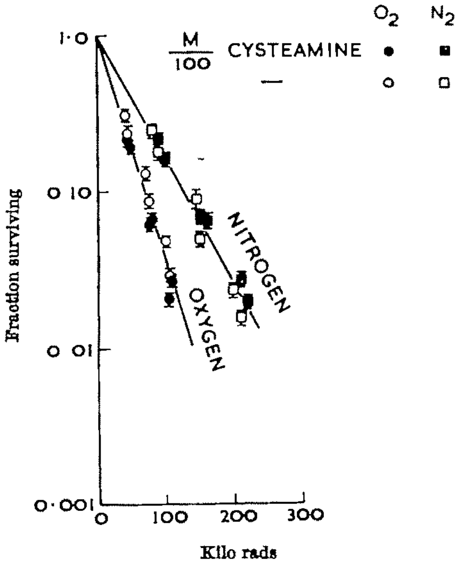

Fig. 2. Effects of 10 m*M* cysteamine and 2 m*M* oxygen on the inactivation of the *T*2–*E. coli B* mono-complex suspended in buffer at *p*H 7

The combined results of duplicate experiments are shown in Fig. 1. It is seen that the rate of inactivation of *T*2 bacteriophage protected by 10 m*M* thiourea was almost independent of the oxygen concentration. On adding cysteamine, there was a marked decrease in the inactivation rate under nitrogen, although most of the effect was abolished in oxygen. These results strongly suggest that oxygen competes very effectively for the radiation-induced injuries in the phage deoxyribonucleic acid which can be restored by the cysteamine. It seems unlikely that the protective effect of cysteamine is due to an improvement in the degree of anoxia to which the phage were subjected, as cysteamine was equally effective in sealed ampoules in the presence of sodium dithionite, which combines rapidly with oxygen at *p*H 7, while the dithionite by itself was without effect. The disulphide form cystamine was not active[8], but cysteine and cysteamine were about equally effective in causing anoxic protection.

It is of interest that after the host *E. coli B* has adsorbed *T*2 phage, the complex so formed is about twice as radiosensitive in oxygen as it is when anoxic[6,10]. As shown in Fig. 2, 10 m*M* cysteamine is without effect on the sensitivity of either the aerobic or anoxic complex. Metabolic steps are not involved in the development of the oxygen effect, since it occurs even if the adsorption takes place in the presence of cyanide.

It appears that an oxygen effect is observed when the phage deoxyribonucleic acid is in the presence of substances with labile hydrogen groups. With free phage, cysteamine or cysteine is effective, while in the case of the phage–bacterium complex, it may be that intra-cellular sulphydryl compounds or other hydrogen donors are involved. The degree of the injury sustained in an irradiation appears to depend upon competition between oxygen and the hydrogen donor[6], presumably for a carbon radical induced by radiation in the phage deoxyribonucleic acid. If this is true, the action of the hydrogen donor is to replace a hydrogen atom on the deoxyribonucleic acid which had been removed by ionization or by radical attack, thus restoring the deoxyribonucleic acid molecule to the active form. The oxygen effect observed with the free phage is smaller than that found with the complex. The explanation of this difference may lie in the difficulty which the sulphydryl compound (or oxygen) may experience in penetrating the phage head membrane and the tightly packed nucleic acid. If these substances are unable to diffuse freely over the surface of the deoxyribonucleic acid molecule, there will be reduced opportunity for reaction with a radiation-induced injury, so that a smaller oxygen effect might be expected. There is some evidence for this explanation in the finding that mature intracellular phage particles show no oxygen effect (unpublished work). If this is the correct explanation, then it is to be expected that transforming principle would show an oxygen effect in the presence of a sulphydryl compound and that the effect might be larger because of greater accessibility to the nucleic acid.

In summary, the reason why oxygen is without effect on the X-ray inactivation of bacteriophage in protective suspension lies in the absence of a suitable hydrogen donor such as a sulphydryl compound. A second factor is that some compounds may experience difficulty in penetrating into the compact structure of the phage head. The oxygen effect on the X-ray inactivation of the complex is presumably a reflexion of the competition between molecular oxygen and intra-cellular hydrogen donors, such as sulphydryl compounds, for the radicals induced by radiation in the phage nucleic acid.

I acknowledge valuable discussions with Dr. N. Symonds and Dr. H. Marcovich, and the assistance of Mrs. Elspeth van Durren. I am indebted to D. K. Bewley and G. Harding, who carried out the irradiation.

Yeast Ribonucleic Acid and its Nucleotides as Recovery Factors in Rats receiving an Acute Whole-Body Dose of X-Rays

It has recently been shown that ribonucleic and deoxyribonucleic acids injected in rats and mice can markedly influence the post-irradiation survival[1-3]; but the exact nature of the mechanism responsible for this beneficial effect is at present unknown. An attempt has been made to give a partial answer to this problem by studying the restorative effect of a ribonucleic acid extracted from yeast, as well as the products of a progressive degradation by controlled alkaline hydrolysis of the same substance, upon rats which had received a single whole-body dose of X-rays. The selected irradiation dose corresponded approximately to the *LD*85(30) for the control animals the death of which was due to acute damage caused to hæmatopoietic tissues. The 30-day survival of the treated animals was taken as a criterion of effectiveness.

The rats used in the experiments were 4 months old male albinos, of an inbred strain raised in the Institute, the body-weight of which varied from 140 to 150 gm. The animals were left un-fed overnight, then irradiated in groups of 4 contained in a 'Lucite' box which was revolved at 2·5 r.p.m. The X-ray unit was a G.E. Maxitron operated at 250 kVp. and 25 m.amp., equipped with a beryllium end-window and additional 0·25 mm. copper + 1 mm. aluminium filters. The half-value layer was 1·15 mm. copper. At a target distance of 80 cm., the delivery-rate averaged 40 r./min. as measured in air with a Victoreen Radocon dosimeter.

The trial solutions, adjusted to a *p*H of 6·5–7, were injected intraperitoneally at a constant volume of 2 ml. per animal. Their tonicity was determined by the freezing point depression method and equalized by the addition of appropriate amounts of sodium chloride with the tonicity of sodium chloride 150 m*M*. 2 ml. of this latter solution were injected into each animal of the control series. 24 hr. after the irradiation, the rats were given an unlimited standard diet. The subsequent mortality-rate and body-weight modification were checked at daily intervals during the 30-day period following the X-ray exposure. Dead animals were subjected to autopsy, and the survivors have been kept for a study of long-term effects.

In the first series of experiments, a dose of 100 mgm. of sodium ribonucleate, corresponding to 72 mgm. of pure ribonucleic acid, was injected within 15 min. of irradiation. Table 1 (rows *A* and *B*) shows the results observed at different X-ray levels between 450 to 550 r. It is clear that the treatment reduces the subsequent mortality-rate. Probit analysis[4] of the results allows the following regression equations to be calculated: $Y = -57{\cdot}05 + 23{\cdot}05 \log_{10}$ r. for the treated animals, and $Y = -41{\cdot}82 + 17{\cdot}72 \log_{10}$ r. for the controls, in which Y is the probit of the percentage of 30-day mortality and r. the X-ray dose in roentgens. There is no significant difference between the regression coefficients. The *LD*50(30) derived from the previous equations are respectively 492·3 r. (5 per cent fiducial limits 504 and 481·5) and 438·7 (5 per cent fiducial limits 451·2 and 427). They differ very significantly from one another ($P < 0{\cdot}001$). Calculation of the corresponding dose-reduction factor gives a value of 1·12. It is noteworthy that a dose-reduction factor of the same order of magnitude,

Table 1. Effects of Injection of Yeast Ribonucleic Acid on the 30-day Mortality of Rats

	X-ray dose (r.)	Number of rats: Per group	Number of rats: Total	Mortality at 30 days (per cent): Per group	Mortality at 30 days (per cent): Total
A. Control series* injected with 2 ml. of saline	550	20	20	100	100
	500	20, 20, 20 20, 20, 20 20, 24, 20	184	85, 80, 75 75, 70, 95 100, 70·8, 85	81·5
	450	10, 12, 20, 20	62	50, 75 70, 75	69·4
	400	20, 20	40	10, 25	17·5
B. Sodium ribonucleic acid (Merck)† injected at a dose of 100 mgm. in 2 ml. saline per animal within 15 min. of irradiation	550	20, 12, 12	44	85, 100, 95	90·9
	500	20, 20 20, 8	68	50, 45 65, 37·5	51·5
	450	20 20	40	25 15	20
C. Sodium ribonucleic acid (Merck)† injected at a dose of 100 mgm. in 2 ml. saline within 15 min. prior to irradiation	500	20 20 20	60	50 60 80	63·3
D. Ribonucleic acid (BDH)‡ injected at a dose of 80 mgm. in 2 ml. saline within 15 min. of irradiation	500	20 20	40	50 50	50

* At each level of irradiation (excepted, 550 r.), the control series include groups injected with saline solution either before or after irradiation. As statistical examination of their mortality after 30 days failed to reveal any difference between the pre- and post-treated groups, it was considered feasible to combine them in a single control group, valid for comparison with the ribonucleic acid pre- and post-injected animals.

† Obtained from Merck Co., Darmstadt, Germany, as the sodium salt of yeast ribonucleic acid. Following the method of Ogur and Rosen (ref. 6) the product has been found to contain 72 per cent of pure ribonucleic acid and 2 per cent of deoxyribonucleic acid. Traces of protein material have been detected.

‡ Ribonucleic acid from yeast, British Drug Houses, Ltd., England. It is converted into its sodium salt by addition of appropriate amount of sodium bicarbonate at 0° C. and injected at a dose corresponding to the ribonucleic acid content of the 'Merck' preparation Both these products, of different commercial origin, seem equally effective

1·17, has been reported for the protective effect of cysteamine on the hæmatopoietic tissues of the same strain of rats[5].

While demonstrating the restorative effects of ribonucleic acid, the above results do not by any means exclude the possibility that this product can also exert a protecting action. To elucidate this point 3 groups of 20 rats were first injected with a similar dose of 100 mgm. sodium ribonucleic acid, then irradiated with 500 r. 15 min. afterwards (Table 1 row *C*). Comparison of their 30-day mortality with those of animals injected after irradiation shows the post-irradiation treatment to be at least as effective as the pre-irradiation treatment. A χ^2 test, in the formula of which the Yates correction of continuity was incorporated[9], failed to reveal any significant difference between these two treatments (calculated $P > 0{\cdot}1$). Therefore, it seems very likely that ribonucleic acid, injected intraperitoneally, acts purely as a recovery factor, without any additional protective effects.

Further experiments were conducted to determine whether the effectiveness of ribonucleic acid is retained after partial degradation of the molecule into nucleotides by controlled alkaline hydrolysis. Two preparations were tested. The first, in which intermediate products were still abundant, was obtained under very mild conditions, while the second consisted of an almost pure mixture of mononucleotides. A comparative inspection of Tables 1 and 2 shows that both these hydrolysates are equally as effective as the native ribonucleic acid and leads to the conclusion that the recovery effect of this substance does not depend upon the integrity of its molecular structure.

Table 2. Decrease of the 30-day Mortality of Rats irradiated with 500 r. by Injection of 2 ml. of Alkaline Hydrolysate of Ribonucleic Acid*

Composition of hydrolysates† (per cent)		Moment of injection	Number of rats: Per group	Number of rats: Total	Mortality at 30 days (per cent): Per group	Mortality at 30 days (per cent): Total
I Oligonucleotides Mononucleotides Residual ribonucleic acid	70 28 0	Within 15 min. of irradiation	20 20	40	30 30	30
		Within 15 min. prior to irradiation	20 20	40	45 45	45
II Oligonucleotides Mononucleotides: Residual ribonucleic acid:	5·7 87·3 0	Within 15 min. of irradiation	20 20	40	50 50	50
III Control series				184		81·5

* Solutions were made up so that their content in nucleotides corresponded to a concentration of 50 mgm./ml. of non-depolymerized 'Merck' sodium ribonucleic acid

† Hydrolysate I was prepared by incubating 1 part of sodium ribonucleic acid 'Merck' with 8 parts of 0·33 *N* sodium hydroxide for 16 hr. at 24° C. Hydrolysate II was prepared according to the method of Davidson and Smellie (ref. 7). Further acidification by perchloric or trichloracetic acid did not give any precipitation in either solution, but caused a slight opalescence due to a trace of deoxyribonucleic acid. A non-mononucleotide fraction was, however, still present and was demonstrated by paper chromatography. The relative concentration of the non-mononucleotide material and the mononucleotide mixture was afterwards analysed by the method of Smith and Allen (ref. 8).

The precise action of ribonucleic acid and its biochemical bases are under investigation at the moment and a full account of this work will be published elsewhere.

BIOLOGY

The Redpoll in New Zealand: Interbreeding Sub-species

Since the opportunity of studying an animal population in which interbreeding and genetical mixing between two hitherto good and mainly allopatric sub-species is taking place must be relatively uncommon, it may be of interest to report on the discovery and preliminary investigation of a situation of this kind occurring in New Zealand.

The redpoll (F. Fringillidae : Aves) was introduced into various parts of New Zealand from about 1862 onwards[1]. The taxonomic status of the introduced birds was originally determined only to the species-level : *Carduelis flammea* (L.) (the present generally accepted nomenclature is used here, following Witherby *et al.*, 1938, "The Handbook of British Birds"). In 1953 Westerskov[2], on the basis of wing and bill measurements and details of plumage coloration of 36 skins collected in New Zealand and some adjacent islands, concluded that only one sub-species, *C.f. cabaret* (P. L. S. Mull.), was present. In the course, however, of an investigation of the ecology of the redpoll and other introduced fringillid species in Canterbury, New Zealand, it has been found necessary to modify Westerskov's conclusion. It appears that at least one other sub-species, notably *C.f. flammea* (L.), is present in the New Zealand populations.

The distinguishing features of the two sub-species *C.f. flammea* and *C.f. cabaret* are given in Table 1.

Table 1. DISTINGUISHING FEATURES OF THE SUB-SPECIES *C. f. flammea* AND *C. f. cabaret*

(After Westerskov, 1953, following Salomonsen, 1928, and Witherby *et al.*, 1938)

	Wing length (mm.)		Bill length (mm.)		General plumage colour	Wing-bar	Body-size
	M	F	M	F			
flammea	71–79	69–76	8–10	7·7–9·1	Paler	Conspicuous whitish	Slightly larger
cabaret	67–73	63–69	8–10	8–9·5	Darker	Inconspicuous buff	Slightly smaller

Observations made on approximately 170 living birds are summarized in the form of frequency-distribution curves for male and female wing-lengths, Fig. 1. The symbols *W* and *p* are given to show the occurrence, at various wing-lengths, of white wing-bar and pale plumage respectively (that is, the occurrence of *flammea*-type plumage characteristics). Reference to bill-length and body-size has been omitted, since nothing significant on these has been obtained in the present sample.

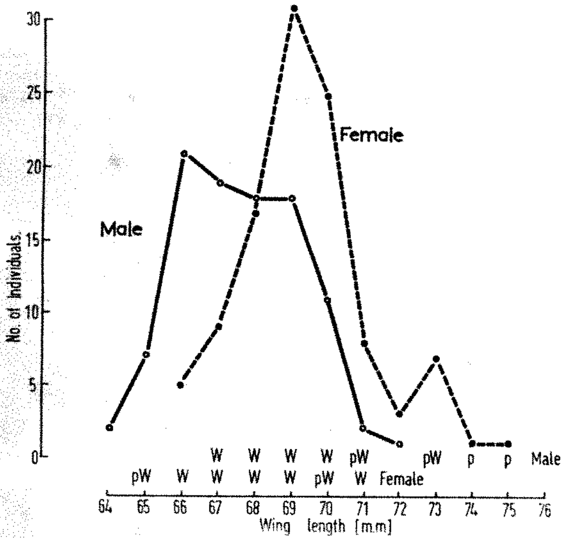

Fig. 1 Redpolls' wing-lengths – frequency distribution curves. *W*, Whitish wing-bar ; *p*, pale plumage

On comparison of Fig. 1 with Table 1, the following points will be noted : (1) The occurrence of individuals above the upper limits of the *cabaret* range of wing-lengths, for both sexes. (2) The absence of individuals in the higher portions of the *flammea* range. (3) The shift of the centres of gravity of the areas enclosed by the curves above the vicinity of the mean for *cabaret*. (4) The occurrence of *flammea*-type plumage characteristics (denoted by *W* and *p*) below the wing-length range for that sub-species.

From the conjunction of these features it seems apparent : (*a*) that the bulk of the population is composed of *cabaret*-type individuals ; (*b*) that a proportion of *flammea*-type individuals, perhaps 10–15 per cent of the population, is present ; (*c*) that the two types are interbreeding, resulting in the mixing of characteristics, for example, the occurrence of *W* and *p* with short wings, etc. (On several occasions, however, small groups of *flammea*-type individuals have been taken together. This suggests that there may still be some tendency to segregation.)

An explanation of the observed deviations from the typical *cabaret* characteristics, alternative to the assumption that one of the larger sub-species is present, may be mentioned in order to be dismissed. The alternative explanation is that the observed deviations from *cabaret* characteristics may be due to an evolutionary change within a pure *cabaret* population. It must be pointed out that this change must have been extremely rapid (the New Zealand populations have been isolated for less than a century) ; that selection pressure must have been low during this time of generally rapid expansion of the populations ; that the direction of the changes, increased wing-length and paler coloration, are the opposite of what would be expected, in an environment on the whole warmer and not less humid than the original, according to Bergmann's and Gloger's rules ; that the simultaneous evolution of several of the characteristics of another sub-species is in any event unlikely, much more so in the present case when the previously mentioned points are considered.

It may be noted that another of the introduced bird populations of New Zealand, that of the yellowhammer, *Emberiza citrinella* L., is now thought to be a mixed population of more than one sub-species, where previously it had been considered that only the British sub-species was present in New Zealand[3].

A number of points still await clarification. It is not yet certain, for example, that the large sub-species is actually *flammea*. The uncertainty arises out of the mixing of characteristics due to interbreeding. This sub-species seems much the most likely component of the present mixed population on the grounds of the observed characteristics (other possible sub-species are even larger than *flammea*—their absence cannot at present be asserted, of course, and in fact slight evidence has been obtained that a very few individuals of one or more or these larger sub-species may be present) and the fact that it is the only sub-species apart from *cabaret* which is found regularly and in appreciable numbers in Britain, the presumed place of origin of the New Zealand populations. (This last presumption is of course very much open to doubt.) It would be interesting, also, to ascertain what were the original proportions of pure *cabaret* and pure *flammea*, if that could be done. The present distribution of the various types will be investigated—this may yield information as to possible modification of the presumed previously existing geographical, behavioural and ecological segregating mechanisms between the two subspecies.

This investigation is continuing, and results will be reported and discussed in full elsewhere.

Yolk Formation in Oocytes of *Patella coerulea* L. and *Aplysia depilans* L. as observed in the Electron Microscope

ELECTRON microscope research on vitellogenesis has so far been mainly concerned with the identification of the precursors, or cellular constituents, from which the yolk formation begins[1-5]. The origin of the yolk and further stages in its formation in oocytes of *Patella coerulea* and *Aplysia depilans* are described here. Small fragments of the female gonads were fixed in a 1 per cent solution of osmium tetroxide at $pH = 7 \cdot 4$ for 1 hr. Other technical details are reported in a previous paper[6]. Preparations and observations were made at the Centre for Electron Microscopy at the University of Padua with a Siemens Elmiskop I*a* apparatus.

In the oocytes of *Patella coerulea*, at the beginning of vitellogenesis, it is possible to observe a reticulum of filaments about 200 Å. thick, which carry dark granulations about 300 Å. in diameter (Fig. 1). Some reticular cavities show a dark content, which gradually increases with the growth of the oocytes, and gives rise to well-formed proteic yolk globules showing an oval form (Fig. 2). Isolated or clustered granulations on their surface appear to enter the developing globules (Fig. 2). They are totally absent when the globules have reached their full development and only the filaments remain (Fig. 3). Previous experiments with ribonuclease showed that granulations are formed mostly by a ribonucleic complex[7].

In the oocyte of *Aplysia depilans*, vitellogenesis starts with the transformation of Golgi bodies or dictyosomes into small globules. They are surrounded, at a given stage, by a semi-lunar structure, which is formed by particles (Fig. 4) of about 950 Å. in diameter. Each particle shows a central clear zone and a peripheral zone which is composed of dark granulations with a diameter of about 300 Å. Many particles strictly adhere to the surface of the globules and it appears that granulations penetrate them (Fig. 4). When the globules are more developed, they show another semi-lunar structure, which is composed of a very dense reticulum (Fig. 5). Some of the biggest globules show some vacuoles (Fig. 5), the presence of which confirms a liquefaction process, which has been previously described[8-10]. Each globule then divides into very minute granules (Fig. 6), which find a place in the cavities (Fig. 7) of the surrounding reticulum. They finally aggregate to give origin to the definitive yolk (Fig. 7).

The electron microscope results give a fair explanation of previous optical microscope observations, which were made both in *Patella coerulea*[11] and in *Aplysia depilans*[8,9]. A very fine alveolar structure of the cytoplasm was observed in the former species along with variations in basophily, and a transformation of dictyosomes into yolk globules was described in the latter. This transformation appeared to be followed by a considerable growth of the globules, which divide to give rise to the smaller globules. Dictyosomes must thus be considered as true precursors in *Aplysia depilans*; no precursors in a strict

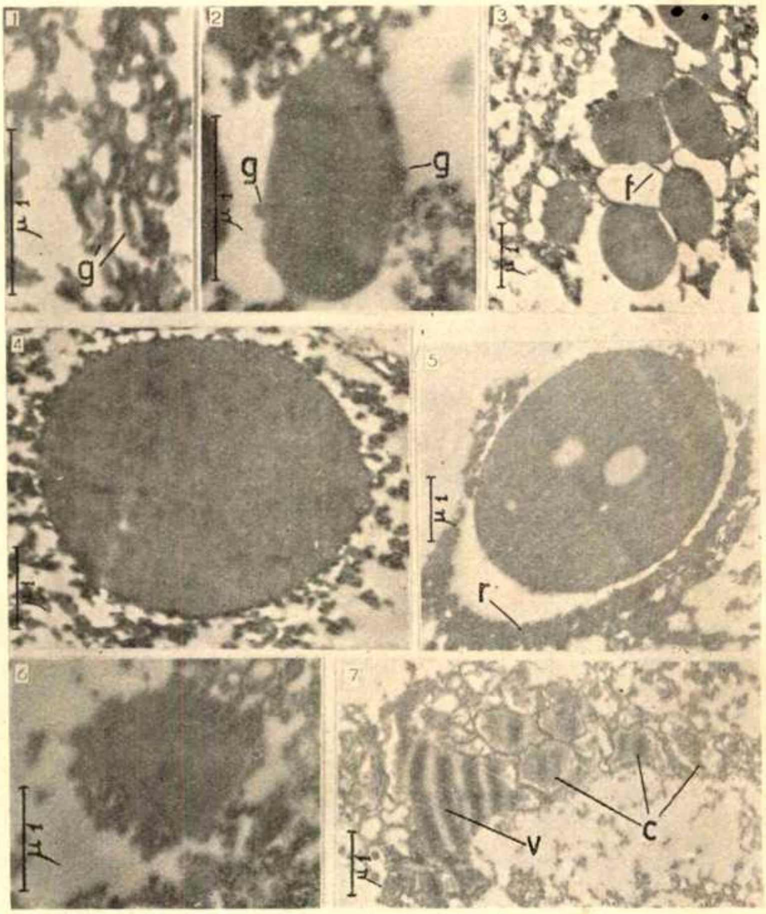

Fig. 1. Ergastoplasm in the oocyte of *Patella coerulea* with dark 300-Å. granulations (*g*). Fig. 2. Yolk globule of *Patella* oocyte with granulations (*g*) on its surface. Fig. 3. Yolk globules of *Patella* oocyte surrounded by filaments (*f*) without dark granulations. Fig. 4. Yolk globule of *Aplysia depilans* oocyte with particles on its surface. Fig. 5. Sex Difference in Accidental Mortality of Guppies exposed to Elevated Temperature

Mass mortalities of fish exposed to low[1–6] and high[7–10] temperatures in Nature have been reported; but no sex differences in such incidents appear to have been recorded. The omission of data on sex ratios may be due to the fact that their interpretation would generally be unsatisfactory since the sex ratios of the original populations would be unknown, and even slight differences in habits of the sexes might result in their exposure being significantly different. In the present instance, interpretation is easier because the exact number of adults of each sex before and after exposure is known.

Over a week-end the temperature of the laboratory in which about 2,000 guppies of unnamed strains being developed for experimental purposes were housed was accidentally raised. At the time the accident was discovered the temperatures in aquaria ranged up to 41° C. and about 150 adult and many young fish were dead. Some adult fish survived in 14 aquaria in which deaths occurred and in which there were adults of both sexes. The results of observations on fatalities and survival among adults in these aquaria are presented in Table 1. Generally, if both immature fish and adults were present the former were almost all dead if any adults were; and in one tank with several large females as well as smaller ones, the smaller ones died and the large ones all survived.

Table 1. Comparison of Survival of Adult Male and Female Guppies exposed to Elevated Temperature

	Male		Female	
	No.	Per cent	No.	Per cent
Surviving	10	32	47	81
Dead	21	68	11	19

The difference in the mortalities of adults of the two sexes has been examined using the chi-square test and found to be statistically significant ($P < 0{\cdot}002$ using the two-tailed test).

The observations here reported agree with the usually observed higher mortality of males[11] and with the laboratory observations of Gibson[12] on survival times of guppies at 37°, although they do not agree with her results at other temperatures. She found that the mean time to death of guppies at 37° was about 50 per cent higher for females than for males. At 34°, on the other hand, the time to death was greater for males (5,660 min.) than for females (3,400 min.) and at other temperatures (35°, 36° and 38°) she found no sex differential.

Before the mass mortality here reported, the sex ratio for adults in the aquaria was 54 males per 100 females; after the accident, 21 males per 100 females. (The original ratio cannot be interpreted as a 'natural' one for some aquaria contained mated groups that had been selected, and fish had been removed from others for experimental purposes.) The observations on this laboratory population suggest that elevations of temperature such as occur in small, shallow, unshaded ponds may bring about significant alterations of the proportions of the sexes.

Stereobalanus, a Genus New to the Old World

During a faunistic survey of all the lochs on the west coast of Scotland from Cape Wrath to the Solway, several pieces and some whole specimens of a golden yellow enteropneust were discovered in bottom samples taken with a 1/10 Van Veen grab (Fig. 1). The geographical location and bathymetric distribution of these specimens are given in Table 1.

In the first four localities the substratum consisted of a layer a few cm. thick of black glutinous mud overlying a stiff clay, but in Loch Glendhu it consisted of a mixture of small stones and mud. As the sampling intensity in all the lochs examined was fairly uniform, it is evident that the species is moderately common and widely distributed along the west coast

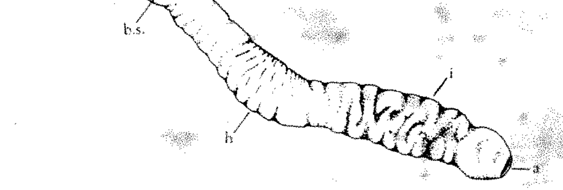

Fig. 1. *Stereobalanus* sp. Line drawing from photograph of live specimen. Overall length, about 8 cm. *a*, Anus; *b.s.*, common branchial slit; *h*, olive green hepatic region; *i*, sac-like intestinal region; *p.r.*, parabranchial ridges

Table 1. DISTRIBUTION OF SPECIMENS FROM WEST COAST LOCHS

Area	Position	Depth (fath.)	Date	No. of specimens
Loch Spelve (Mull)	56° 24·3′ N. 5° 43·5′ W.	8	5.6.57	1
Loch Spelve (Mull)	56° 24·1′ N. 5° 43·5′ W.	9	7.10.58	2
Loch Sunart (Glenmore Bay)	56° 40·8′ N. 5° 55·9′ W.	9	11.6.57	1
Loch Erisort (Lewis)	58° 7·4′ N. 6° 23′ W.	20	15.10.58	3
Loch Glendhu (Sutherland)	58° 15·4′ N. 4° 57′ W.	7	22.10.58	1

of Scotland and perhaps significant that it was not found in any of the samples taken south of Mull. A preliminary analysis of the associated fauna expressed as numbers per 1/10 m.^{2} is summarized in Table 2.

The pronounced radial arrangement of the longitudinal muscles and thick enveloping layer of circular muscles and reduced condition of the coelom in the proboscis, the absence in the mesosoma of complete dorsal and ventral mesenteries and collar pores, the very prominent dorso-lateral and ventro-lateral parabranchial ridges enveloping the branchial apertures, the rudimentary peripharyngeal cavities and the absence of any trace of œsophageal pores, justify the identification of this enteropneust as a species of the genus *Stereobalanus* Spengel.

The type material upon which this genus was established was first dredged off Cape Breton, Nova Scotia, in 1873, by the late Prof. W. C. McIntosh, and originally named *Balanoglossus canadensis* by Spengel[1]; afterwards, in a review of the nomenclature of certain of the Enteropneusta, Spengel established a new genus for this species and it became *Stereobalanus canadensis*[2]. It was later rediscovered by Reinhard[3] some 430 miles away from the type locality at the mouth of Sullivan's River, Frenchman's Bay, Maine, where it occurred in considerable numbers in a 'soft, fine mud' substratum together with *Corymorpha pendula*, *Nephthys caeca* and *Ctenodiscus crispatus*. It has also been found at San Diego, California (Bullock, T. H., and Rao, K. P., unpublished work).

The only other species of the genus recorded (*S. willeyi* Ritter) was found in San Pedro Channel, New Port, California, where fragments of specimens were discovered in very soft sandy mud taken from a depth of about 40 fm.[4].

Table 2. ANALYSIS OF THE ASSOCIATED FAUNA

Animal	Numbers per 1/10 m.^{2}			
	Spelve	Erisort	Glendhu	Sunart
Mysella bidentata (Montagu)	87	1	—	—
Other lamellibranchs	3	3	5	1
Loricata	—	—	7	—
Heterocirrus sp.	53	—	—	46
Pholoe minuta (Fabricius)	2	1	1	—
Eumenia crassa Oersted	3	—	1	—
Nephthys hystricis McIntosh	4	2	—	4
Notomastus latericeus M. Sars	1	—	2	1
Lumbriconereis hibernica McIntosh	2	4	4	—
Glycera sp.	—	2	4	—
Other polychaetes	10	20	25	6
Amphiura filiformis (O. F. Müller)	17	48	1	—
Amphiura chiajei Forbes	1	19	1	2
Other echinoderms	—	5	1	—
Ampelisca diadema (A. Costa)	1	1	2	—
Other amphipods	—	1	—	—
Cumacea	—	1	—	—

Although the specificity of the Scottish species cannot be determined without a more detailed comparative study, a preliminary examination of the general anatomy shows that it is more closely allied with *S. canadensis* than with *S. willeyi*.

Hitherto, the genus has been indigenous to the east and west coasts of North America. Its discovery in a comparable habitat in the Old World is therefore of considerable interest, and if it proves to be *S. canadensis* then it will provide yet another instance of the discontinuous distribution recorded for certain members of this phylum. It also makes an important addition to the number of Enteropneusta already recorded from the British Isles[5,6].

We are grateful to Prof. T. H. Bullock and Dr. K. P. Rao for a copy of their manuscript on this genus, and to Dr. J. S. Ryland for his assistance with the collection and preservation of the material and also for taking the photograph from which Fig. 1 was drawn.

Effect of a Sewage Effluent Discharge on the Deposition of Calcium Carbonate on Shells of the Snail *Potamopyrgus jenkinsi* (Smith)

DURING an ecological survey of the River Ivel[1], a chalk stream in Bedfordshire, it was observed that shells of the snail *Potamopyrgus jenkinsi* (Smith) were heavily encrusted with calcareous nodules upstream of a sewage effluent discharge whereas downstream of the discharge such shells were clean (Fig. 1). Above the sewage effluent, snails were more than 70 per cent heavier than those below the effluent (Table 1).

Table 1. A COMPARISON OF WEIGHTS OF SNAILS TAKEN FROM ABOVE AND BELOW THE SEWAGE EFFLUENT (AVERAGE OF 12 DETERMINATIONS)

Location	Width of shell aperture (mm.)	Dry weight (mgm.)	Calcium carbonate (mgm.)
Above effluent	1·50	2·98	2·44
Below effluent	1·46	1·73	1·42

Snails taken from below the discharge and placed in cages above it developed encrustations within three weeks. Warwick[2] referred to calcareous encrustations found on *P. jenkinsi* in a limestone district of Derbyshire but no demarcation of habitat effect was observed. Deposition also occurred on

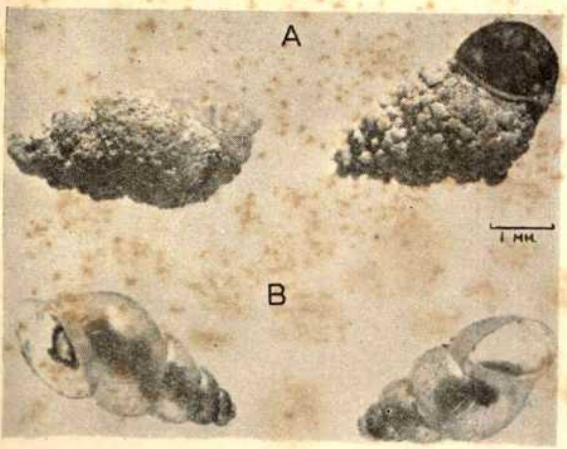

Fig. 1. *Potamopyrgus jenkinsi* shells from an unpolluted stretch of river showing calcareous encrustations (*A*) and from a polluted stretch (*B*)

glass slides immersed in the River Ivel upstream of the effluent. The *p*H value of the river water both above and below the effluent varied between 7·9 and 8·3 on the several occasions on which it was determined. Total hardness was about 290 p.p.m. as calcium carbonate. The algal flora on the snail shells was dominated by *Cocconeis* and '*Chantransia*' both upstream and downstream of the discharge. The effluent was of good quality (Table 2) and constituted between 5 and 10 per cent of the dry summer flow.

Table 2. ANALYSIS OF SEWAGE EFFLUENT

	Concentration (p.p.m.)	Number of samples
Organic carbon (as C)	22	3
Ammonia (as N)	1·7	2
Nitrite (as N)	0·1	2
Oxidized nitrogen (as N)	70	2
Phosphate (as P)	10·3	3
Synthetic detergent (as 'Manoxol O.T.')	5·2	4
Permanganate value	7	2
3 day B.O.D.	11	2
Suspended solids	10	2

Laboratory experiments were conducted in which glass slides were immersed in: (*a*) river water; (*b*) river water plus sewage effluent (5 per cent by volume); (*c*) river water plus synthetic sewage effluent containing no synthetic detergents[3] (5 per cent by volume); (*d*) river water plus sodium carboxymethyl cellulose (5 p.p.m.); and (*e*) river water plus sodium hexametaphosphate (1 p.p.m. as phosphorus) at *p*H 8·2 and 8·5.

Deposition occurred only on those slides immersed in river water without additives. The sample of sewage effluent used in the above experiments contained 52 p.p.m. total organic carbon, 4·5 p.p.m. synthetic anionic detergent (as 'Manoxol O.T.'), and 5·2 p.p.m. phosphate (as phosphorus). The synthetic sewage effluent contained 24 p.p.m. total organic carbon and 2·6 p.p.m. phosphate (as phosphorus).

It is evident that sewage effluents contain several constituents which prevent the deposition and aggregation of calcium carbonate under conditions similar to those prevailing in the River Ivel. Certain constituents of packaged detergents and soaps, such as condensed phosphates which sequester calcium and magnesium ions and act as dispersive agents, and organic soil suspenders such as sodium carboxymethyl cellulose[4] may be of importance. It seems likely, from experiments with sewage effluent prepared without synthetic detergents, that other agents inhibiting deposition are also present. Similar conclusions were drawn by Alekin and Moritschewa[5] from their observations on the Don and Volga. It would seem, from their work, that certain organic substances present in these waters are inhibitors of calcium carbonate deposition, particularly humus material of plant origin.

Occurrence of *Halimeda opuntia* var. *minor* on Jamaican Shores

I WISH to report the presence of *Halimeda opuntia* var. *minor* on Jamaican shores. The variety was confirmed by Miss Lena Pierce at the Institute of Jamaica.

It was found in water 1–2 ft. deep, at the eastern end of the barrier reef protecting the west harbour at Port Antonio, in the passage between the reef and Navy Island, on July 17, 1959.

It is not common, but several clusters are scattered around and easily distinguished from the more normal variety by the fine construction.

Although found on other Caribbean islands, this is the first time this variety has been discovered in Jamaica.

P. F. JAMES

Box 120,
Port Antonio,

Living and Fossil Unicellular Algæ and Aplanospores

IN studies of peat deposits from south-western Australia, a number of small fossil algæ have been found with a morphology similar to certain living polyhedral unicellular species of the family Oocystaceae of the Chlorococcales. The classification of this family is artificial[1] and is based on the type of colony produced. Genera which have been placed in the family include *Tetraedron*, *Desmatractum*, *Octogoniella* and *Scotiella*[1–3]. Two of these, *Octogoniella* and *Desmatractum*, have a peculiar form characterized by two envelopes, separated by a more or less wide space containing an aqueous mucilage. The inner envelope is delicate, while the outer is composed of two conical halves joined together in the median plane.

Three distinct fossil algae, which match the forms described, have been found preserved in Western Australian peats of various ages between 4000 B.C. and the present. These are illustrated in Fig. 1, Nos. 2, 4 and 7. The principal difference between the

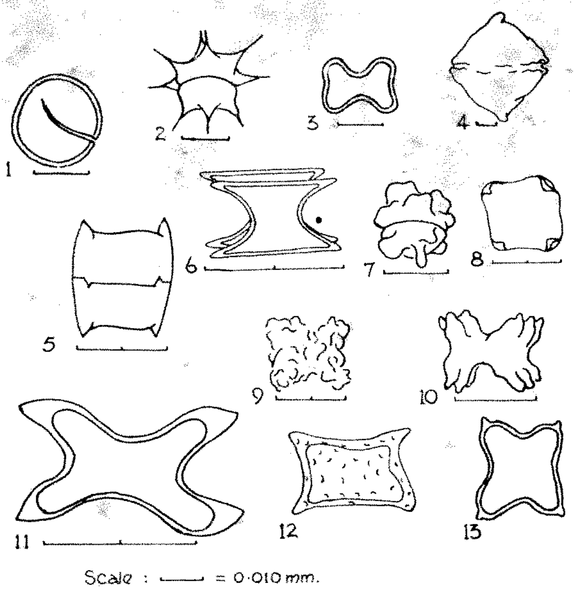

Fig. 1. Fossil algae of the Cyanophyceae: from a recent peat at Walpole (2 and 7) and Lake Muir (4). Fossil algal aplanospores: from a recent peat at Walpole (1, 5 and 11) and Lake Chittering (8). From a Lower Eocene glauconitic shale between 1,285 and 3,185 ft. in the Rottnest Bore (3, 9 and 10). From the Palæocene in the King's Park shale at 164 ft., Narrows Bore, No. 2 (6). Nos. 12 and 13 are living spores (refs. 2 and 3)

fossil forms and the living forms is the absence of the internal envelope of the protoplast, which is presumed to have been lost either after death of the organism, or during the processing of the peats for extraction of the microflora.

Fossil algal aplanospores have also been found preserved in peat sediments from a number of swamps and these are illustrated in Fig. 1, Nos. 1, 5, 8 and 11. Aplanospores are transported by the wind, as they have been found trapped with atmospheric pollen, in dried pinnules of tall *Schizaea* plants.

A palynological analysis of a peat profile from a swamp near Walpole, Western Australia, into which algal aplanospores are at present blown, suggested that a large number of the aplanospores were preserved under freshwater-lake conditions between 4700 B.C. and 600 B.C. Since then, with the rapid expansion of sedges and Hystrichosphaerideae, bog conditions have developed. Water in the bog has become more saline than in the lake and the number of preserved aplanospores diminished rapidly. The increased salinity is thought to favour germination of the aplanospores, after which they are no longer preserved.

Fossil aplanospores also occur in lower Tertiary glauconitic shales from the Perth Basin and these are illustrated in Fig. 1, Nos. 3, 6, 9, and 10. From finding these spores in sedimentary rocks, it is suggested that they may be of value as stratigraphic fossils and salinity indicators, while a detailed study of aplanospores from living families may enable a closer insight into the fossil history of the algae.

Water-Soluble Methacrylates as Embedding Media for Preparation of Ultra-Thin Sections

AT present, the embedding of preparations for cutting of ultra-thin sections is most frequently carried out by the procedure originally described by Newman *et al.*[1] and later perfected by a number of other authors[2-4]. This method, however, suffers from the drawback that the embedding media used are, in their monomeric form, immiscible with water and usually good solvents of fats. The preparation must be dehydrated—usually with alcohol or other organic solvent—before embedding and this, together with the solving of fats, may lead to the alteration of biological structures and formation of artefacts.

These disadvantages might be expected to be avoided by using an embedding medium which is completely miscible with water in its monomeric form. This condition is met by a mixture of two monomers prepared by Wichterle and Lím[5]—glycol monomethacrylate and triethyleneglycol dimethacrylate. These compounds are prepared by a procedure based on re-esterification of methyl methacrylate with ethylene glycol and triethylene glycol, respectively.

Both monomers are clear, colourless liquids at room temperature of a viscosity somewhat higher than that of water, and stable indefinitely at 0–4° C. The triethyleneglycol dimethacrylate serves as a cross-linking agent and is added in a ratio of about 1 : 100. When an accelerator is added (for example, ammonium persulphate) the polymerization proceeds uniformly at about 40–50° C. or under the influence of ultraviolet radiation for about 12 hr. and results in a clear, transparent polymer of three-dimensional structure. It was noted that polymerization is greatly accelerated by the presence of even traces of different co-catalysts, for example; also by osmium oxides. This is a particular advantage especially in the case of preparations fixed with osmium tetroxide. The final properties of the polymer—particularly its hardness—can be controlled by adjusting the ratio of the two monomers and especially the water content of the mixture.

Embedding in glycolmethacrylate for cutting ultra-thin sections can be carried out by two procedures. Since an isotonic aqueous solution of the monomers does not appear to cause alteration of biological materials, the structure of the preparation may first be fixed in a mild manner by polymerization in an isotonic monomer solution. Mechanical fixation of the biological structure is assumed after this first step, although a relatively soft polymer is formed. Further hardening of the primary gel is then achieved by stepwise replacement of the water by monomer followed always by polymerization.

Although it is a little time-consuming, this procedure, according to our preliminary results, appears to be milder than the alternative method in which the preparation is passed through a series of aqueous monomer solutions of gradually increasing concentration in the same way as is usual with alcoholic solutions.

Preparations embedded by either procedure show a satisfactory hardness. A disadvantage is a certain swelling of the block in water which results in a decrease in hardness during cutting. We are at present trying to eliminate this drawback.

The sections which we have obtained so far were found to spread very well on the surface of aqueous ethanol containing lanthanum nitrate, and were easily picked up from the surface.

The technique for cutting ultrathin sections described here is being developed and further details will be published soon.

A New Specimen of *Nipa* Fruit from Mohgaonkalan Cherts

The fruit *Nipa hindi* (Rode) Sahni was collected by Prof. K. P. Rode from Intertrappean beds of Mohgaonkalan, Chhindwara District, in 1933. So far it has been a holotype of *Nipa* from Deccan Intertrappeans of India.

A fresh specimen has been collected by me recently from the same locality. It differs from *Nipa hindi* (Rode) Sahni in size, shape, structure of internal seed, and the characters of the endocarp. However, the importance of the discovery of a new specimen is undoubtedly unique. Presence of *Nipa* fruit is very characteristic of the Eocene period; younger records are not yet known. Accordingly, on the discovery of Rode's only specimen of *Nipa hindi*, Prof. Sahni[1] had suggested an Eocene age for Intertrappeans at Mohgaonkalan. This new specimen falls in line and brings more support to Prof. Sahni's view on the age of the Deccan Traps of India. Hislop too had recorded this fruit in Deccan cherts in the publications by Carter[2], Hislop[3], and Hislop and Hunter[4]; but unfortunately his specimens are untraceable. Almost all the known records of *Nipa* show its existence roughly along the shore of the Nummulitic sea (Tethys), as indicated by Reid and Chandler[5], which probably extended from about north of Chhindwara.

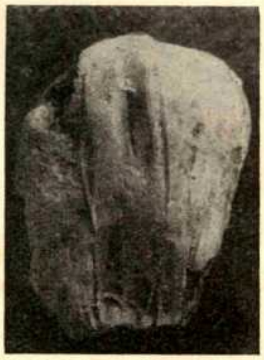

Fig. 1. *Nipa* fruit from Mohgaonkalan cherts. ×0·6

Fig. 1 shows a complete fossil fruit comparable to modern *Nipa fruticans*. The fruit is a single-seeded drupe, slightly flattened, obovoid, with six longitudinal ridges which meet at the apical distinct umbo. It measures 6·5 cm. in length and 5 cm. in breadth at its broadest distal part. The carpel wall is thick especially at the apex. The epicarp is thin and smooth, the sarcocarp is about 10 mm. thick, and the endocarp is about 0·8 mm. thick. The single seed inside is slightly flattened, and has a prominent sulcus with endocarpic ridge dipping into it. The sulcus with the endocarpic ridge extends from the base to the top of the seed.

Preservation of the material is satisfactory and structural details are under further investigation.

Variation in *Phytophthora palmivora* (Butl.) Butl. on *Theobroma cacao* L. in West Africa

Diseases of *Theobroma cacao* L., particularly pod-rot, caused by *Phytophthora palmivora* (Butl.) Butl., have been described in all the cocoa-producing areas of West Africa. A large collection of isolates from most territories, however, has shown that the nature of the pathogen varies greatly in the region and that at least two types of the fungus exist.

The first type of isolate, referred to as the Ghanaian type, is the dominant fungal pathogen in the more westerly cocoa-growing countries of Ghana, Ivory Coast, and Sierra Leone. This type occurs occasionally in Nigeria, Southern Cameroons, Gabon and the Belgian Congo. The isolates are characterized by cultural and morphological features typical of *P. palmivora*, and also have rapid growth-rates when inoculated into healthy pods. Minor differences have been found between isolates within the group, but for the most part they are indistinguishable.

The isolates of the second, or Nigerian, group, which are the dominant pathogens in the more easterly countries of Nigeria, Southern Cameroons, Fernando Po, French Cameroons and probably Gabon, show marked differences from the Ghanaian type. Cultural and morphological characters are very dissimilar, especially in growth-rates on artificial media and in sporangial dimensions, and the rate of lesion development in pods is both appreciably slower and very variable. Current tests have shown that complementary strains for oospore production occur within the group. Mixed cultures of the two groups of isolates grown on oatmeal agar at 60° F. have been found to produce oospores. Dimensions of these spores corresponded to those described by Ashby[1] on growing cultures of the 'cocoa' and 'rubber' groups of the fungus together under similar conditions. No oospore production has been obtained by cross in any isolates from the westerly group of countries.

The occurrence of complementary isolates within a particular territory could result in genetic variation of the organism and possible changes in its pathogenicity. Varieties of *Theobroma cacao* now being bred for resistance and tolerance to black-pod disease will need more extensive testing in areas where the pathogen is variable than may be necessary in Ghana, where it appears to be uniform. The variability of the organism must also be recognized when conducting bio-assays of fungicides to be used in chemical control of the disease in the field.

Further investigations are proceeding, and a fuller account of the work will be published elsewhere.

ANATOMY

A Reconstruction of the Foot of the 'Abominable Snowman'

THE clearness of the tracks of the 'Snowman' shown in the photograph taken by Eric Shipton[1] (Fig. 1) has enabled me to make a reconstruction of its foot (Fig. 2). This has been used to produce imprints in snow which show a great similarity to the natural tracks (Figs. 1 and 3), suggesting that the model is accurate.

The plaster foot has the following anatomical peculiarities: (1) It is of great size: length 12½ in., fore breadth 7½ in., the width thus being 60 per cent of the length. The heel is 6½ in. broad—nearly as broad as the fore part of the sole. (2) The hallux is very thick and separated from other toes. (3) The second is the longest toe, and it is separated from the hallux and third toe; it is thinner than the hallux though more powerful than the other toes. (4) The third, fourth and fifth toes are small and united towards their bases, although the distal end of each toe gives a clear impression in the snow. The little toe is less bent than the others.

These features can be seen to a lesser degree in human and gorilla feet, and by comparing them certain inferences can be made.

(1) The 'Snowman' foot is as long as that of a large gorilla but much broader. Sir Arthur Keith[2] emphasized the increase of the tarsal, and decrease of the digital, elements of the skeleton of the foot during the evolution of higher primates. In the foot of the gorilla, the tarsal elements account for 39 per cent of the length measured along the third digit; in the human foot, it accounts for 52 per cent. At the same time, describing the soft tissues of sole, Keith states: "we see the enormous increase of the heel in the gorilla; it is relatively and absolutely larger than the heel area of man". Fig. 4 shows this huge foot and it can be seen that it resembles the much larger heel of the Snowman. This may equally be regarded as a combination of the hominoid tendency towards increasing length and breadth of tarsal bones together with gorilloid tendency for a spread of the soft tissues. The great fore breadth (42·8 per cent of the length) is found also in the skeleton of the foot of the neanderthaloid from the Kiik Koba cave in the Crimea[3].

(2) The hallux of the 'Snowman' resembles that of the gorilla, except that it is straighter, longer and much more powerful. In conjunction with the depth of the impression made in the snow, this suggests that it carried much of the weight of the body. But at the same time the hallux has every appearance of being opposable, and could be used to grasp objects or in climbing. The first row of foot bones is shortest because of a very shortened metatarsal element, although the phalanges themselves are big. R. Neuhaus[4] and H. Virchow[5] call such cases in human foot (Fig. 5) "zurücktretende" hallux and they appear, as in the 'Snowman', to be due to an unusually short metatarsal bone.

(3) The unusually large size of the second toe of the 'Snowman' can be also compared with the human foot with "zurücktretende" hallux. This type of big toe can be accompanied with an elongated and thickened second toe (Fig. 5). H. Klaatsch[6] has described a similar case in an Australian aborigine, who possessed the same type of foot which was able to grasp much better than normal. This is the same combination of shortened first and elongated second axis both in the foot of the 'Snowman' and in an abnormal human foot.

These peculiarities can be explained functionally. The hallux is shortened and capable of grasping, but

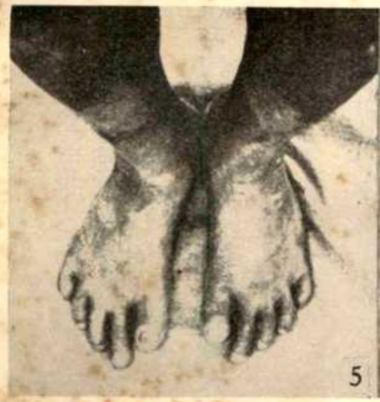
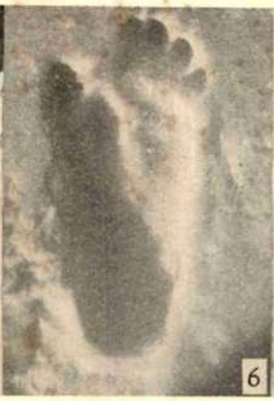
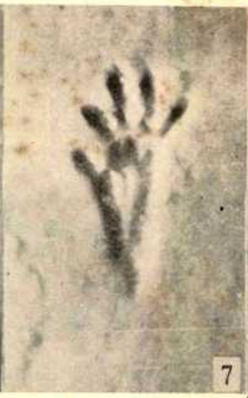
Fig. 4. Plaster cast of a gorilla's foot







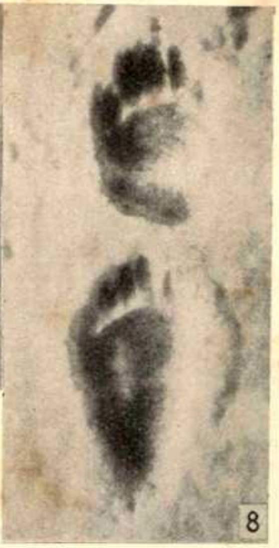


Fig. 5. The "zurücktretende" hallux in human feet (after Neuhaus)
Fig. 6. Artificial track of *Gorilla beringei*
Fig. 7. Artificial track of a langur
Fig. 8. Tracks of the fore and hind paws of the Himalayan black bear

less effective for use in walking upright. The second toe is therefore also involved in balancing and is elongated and thickened. This type of foot with its dual functions of grasping and balancing was probably characteristic of early prehominids in the first stages of the bipedal mode of life.

(4) The relative shortness of digits 3, 4 and 5 and their corresponding metatarsals are an obvious feature of the human foot. Also all three lateral toes of the 'Snowman' seem to show signs of partial syndactyly, but metatarsals 3–5 do not show any signs of the shortening which is observed in the human foot. The two distal phalanges of the little toe in the human foot are often fused together, and this condition may also explain the faintness of the impression made by the little toe of the foot of the 'Snowman', which we must suppose was held straighter than the others.

The impressions made by plaster casts of the feet of the mountain gorilla (Fig. 6), langur (Fig. 7) and the tracks from the preserved feet of black bear (Fig. 8) show that the footprint of the 'Snowman' is much like that of the gorilla and very different from the other two. Yet it has been suggested that Shipton's photograph was a footprint of either a bear or langur.

Other criticisms that the footprint of the 'Snowman' was deformed by the melting of the snow do not seem well founded, in view of the sharpness of the imprint and the similarity to the fresh artificial prints from the plaster model.

Hans Gross[7] mentions that good photographs of the tracks in the snow show even more details than do a plaster cast made from such tracks. But since heel and toes press more deeply into the snow than the sole, the arch of the foot is exaggerated and the impression is slightly shorter than the actual foot.

G. W. Gayer[8] stressed that the deepest impressions of human tracks are: the outer side of the back of the heel and on the inner side the big toe, and slightly less the outer side of the sole behind the little toe and the inner side behind the hallux. These details are well known from criminological studies and are very clearly seen in the tracks and plaster cast of the 'Snowman'.

In the original photograph it is also possible to see small heaps of snow thrown up by the back of the heel when it first touched the snow surface and was later pressed down by the flat of the heel, which is, according to Gayer, characteristic of the track of a bare human foot. This suggests that the track of the 'Snowman' was formed in the same way as a human one and that the 'Snowman' must walk in a human manner.

All the evidence therefore suggests that the so-called 'Snowman' is a very huge, heavily built bipedal primate, most probably of a similar type to the fossil *Gigantopithecus*.

CYTOLOGY

Chromosomes of *Gyraulus circumstratius*, a Freshwater Snail

Polyploidy is relatively scarce in the animal kingdom, and is apparently almost entirely confined to those species in which reproduction is parthenogenetic, hermaphroditic or clonal[1]. Such animals usually do not have a heterogametous sex-determining mechanism to be disturbed by polyploidy. The hermaphroditic nature of freshwater pulmonate snails and their ability for self-fertilization[2] suggest the possibility that there might be a considerable degree of polyploidy among the large number of species of this group because a single accidental polyploid individual could give rise by self-fertilization to a polyploid strain, rather than producing only sterile triploids, if cross-fertilization were obligatory[3]. So far there has been little reliable evidence for polyploidy in aquatic pulmonate snails. (An earlier indication of polyploidy, based on the chromosome numbers reported for *Physa gyrina*[4], and *P. acuta* (=*integra*?)[5] $n = 6$ and 18, respectively, is due to erroneous observations concerning *P. gyrina*). Six specimens of this species from several localities in Colorado from which animals were taken for the earlier investigation were found to have haploid chromosome numbers of eighteen (J. B. Burch, unpublished work). The high chromosome number ($n = c.\ 59$) reported for the limpet *Ancylastrum costulatum* (=*Ancylus fluviatilus* Müller?) was not considered to be polyploid, but due to diphylogeny in freshwater snails[6].

During recent investigations of the chromosomes of freshwater snails we have had the opportunity to study *Gyraulus* (*Torquis*) *circumstriatus* (Tryon). Specimens were obtained from a mill pond on highway *M*–132, Section 5, Scio Township, Dexter, Washtenaw County, Michigan, U.S.A. Identifications were made by Dwight W. Taylor, U.S. Geological Survey. Duplicate shells have been deposited in the collections of the Museum of Zoology, University of Michigan (*UMMZ* 197464), and the United States National Museum (*USNM* 628895). The material examined consisted of ovotestes of ten specimens, all in active stages of gametogenesis. The tissues were sectioned and stained by Newton's crystal violet following fixation in Sanfelice, and acetic-orcein squashes were prepared following fixation in Newcomer's fluid[7]. Observations were made with a Tiyoda microscope using a ×90 (n.a. 1·25) oil immersion objective and ×10–30 oculars.

All specimens of *Gyraulus circumstriatus* were found to have thirty-six elements (presumably all bivalents) present during late prophase and metaphase of the first meiotic division of spermatogenesis (Fig. 1). So far as could be determined, the pairing behaviour of the bivalents appeared to be normal, and during diakinesis the paired chromosomes were held together by one or more chiasmata.

Exact counts on gonial metaphase cells could not be made, but they contained about seventy-two chromosomes. As seen in squash preparations gonial metaphase chromosomes are monocentric, with median, submedian, or subterminal primary constrictions. This is in contrast to the 'dot-like' mitotic chromosomes described from sectioned material of *Gyraulus hiemantium* and considered to be characteristic of aquatic pulmonate snails[8].

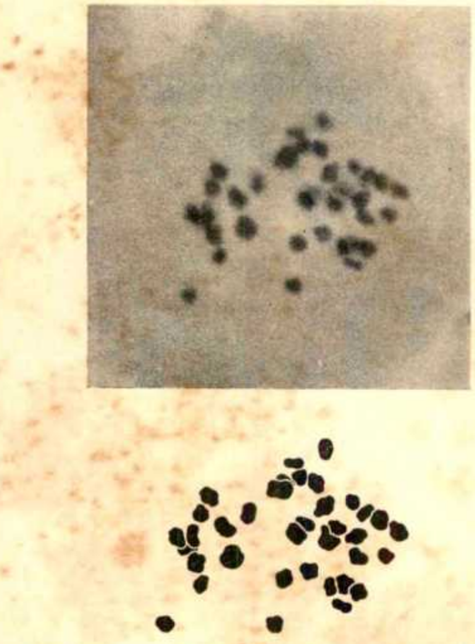

Fig. 1. Photograph and camera lucida drawing of prometaphase chromosomes of *Gyraulus circumstriatus* during the first meiotic division of spermatogenesis

Table 1. CHROMOSOME NUMBERS IN PLANORBID SNAILS

Species	Haploid No.	Diploid No.	Investigator
Anisus vortex	18	—	Le Calvez and Certain (ref. 6)
Gyraulus hiemantium	16	32	Inaba and Tanaka (ref. 8)
G. deflectus	18	36	Burch (ref. 9)
G. circumstriatus	36	*c.* 72	Burch (ref. 9)
Biomphalaria glabratus	18	—	Azevedo and Gonçalves (ref. 11)
olivaceus	18	—	Burch (ref. 9).
Helisoma subcrenatum	—	36	Bonham (ref. 10)
H. anceps	18	—	Burch (ref. 9)
H. trivolvis	18	36	Burch (ref. 9).
Planorbarius corneus	17	—	Azevedo and Gonçalves (ref. 11)
P. cornuta (= *corneus* ?)	18	—	Le Calvez and Certain (ref. 6)
Promenetus exacuous	18	—	Burch (ref. 9).

Chromosome numbers found in planorbid snails are shown in Table 1. It is interesting to note that with the exception of two species, *Gyraulus hiemantium* (Japan) and *Planorbarius corneus* (Portugal?), all species other than *Gyraulus circumstriatus* have a haploid chromosome number of eighteen. It should be emphasized also that this is the haploid number of the only closely related North American species studied, *Gyraulus deflectus*. These numbers, together with the hermaphroditic nature and ability for self-fertilization of planorbid snails, strongly suggest that *Gyraulus circumstriatus* is polyploid, that is, tetraploid. If this is true it is the first case of polyploidy to be found in pulmonate snails. The apparent rarity of polyploidy in snails indicates that this is not a major factor in the evolution of this group.

This investigation was supported (in part) by a research grant, *E*–952, from the National Institute of Allergy and Infectious Diseases, U.S. Public Health Service. Grateful acknowledgment is made to Linda L. Bush, Department of Biology, Western Michigan University, for technical assistance and to Henry van der Schalie, University of Michigan, for facilities and many kindnesses.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, May 9

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 4 p.m.—Prof. Feodor Lynen (Munich): "Co-enzyme A and Fat Metabolism".*

University of London (at the Wright–Fleming Institute of Microbiology, St. Mary's Hospital Medical School, Norfolk Place, London, W.2), at 5 p.m.—Prof. A. Nenberger, F.R.S.: "The Digestion and Absorption of Protein in Normal Man and in some Pathogenic Conditions".* (Second of four Almroth Wright Lectures. Further Lectures on May 16 and 23.)

University College (in the Gustave Tuck Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. T. Kotarbinski (Polish Academy of Sciences, Warsaw): "Some Reflections on Praxiology. The Effectiveness of Human Actions".* (Further lectures on May 11 and 13.)

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Prof. J. M. Kay: "The Generation of Power". (First of three Cantor Lectures on "Energy".)

Tuesday, May 10

University of London (at the Institute of Obstetrics and Gynæcology, Hammersmith Hospital, London, W.12), at 2 p.m.—Prof. C. Scott Russell: "Pregnanediol".*

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Sir Olaf Caroe: "The Pathans" (Sir George Birdwood Memorial Lecture).

Wednesday, May 11

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Alwyn Williams: "The Stratigraphy and Brachiopod Faunas of the Caradocian Rocks of the Girvan District, South-West Ayrshire".

University of London (in the Wright–Fleming Institute Theatre, St Mary's Hospital Medical School, Norfolk Place, London, W.2), at 5 p.m.—Prof. G. W. Thorn (Harvard): "Current Concepts: Glucocorticoids and Gluconeogenesis".*

Institution of Electrical Engineers, Supply Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. G. Jancke: "The Development of the 400 kV. Network in Sweden".

University College (in the Physics Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. M. Nicolet (Institut Royal Météorologique de Belgique): "Solar Radiations and their Effects on the Upper Atmosphere".* (Further lecture on May 12.)

Challenger Society (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 5.45 p.m.—Annual General Meeting, followed by Dr. H. F. P. Herdman: "Modern Trends in Research Ship Design".

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 6 p.m.—Mr. C. M. Vignoles: "Petroleum People—Planning for To-morrow" (Presidential Address).

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. A. E. Adams: "A Recording Stereocomparator".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. O. R. Frisch, F.R.S.: "Are the Laws of Nature Symmetrical?".

Thursday, May 12

Physical Society, Optical Group (at the National Physical Laboratory, Teddington, Middlesex), at 11.15 a.m.—Scientific Papers.

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. P. M. S. Blackett, F.R.S., Mr. J. A. Clegg and Mr. P. H. S. Stubbs: "An Analysis of Rock Magnetic Data"; Prof. W. H. McCrea, F.R.S.: "The Origin of the Solar System".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. J. H. Mason: "The Resistance of Sheet Insulation to Surface Discharges".

Royal Aeronautical Society, Astronautics and Guided Flight Section (at the Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1), at 6 p.m.—Mr. J. E. Allen: "On Reducing Costs of Space Research".

Friday, May 13

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. V. A. Ambartsumiam: "The Evolution of Stellar Systems" (George Darwin Memorial Lecture)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant, Grade B (graduate, preferably possessing a degree which includes biological subjects and chemistry or physics) in the Natural Science Department, to teach biology to G.C.E. "A" level, human biology to G.C.E. "O" level, and elementary science—The Principal, Derby and District College of Technology, Kedleston Road, Derby (May 14).

Assistant Experimental Officer (graduate in chemistry, but those graduating in 1960 considered), for soil and plant analysis with sugar beet field experiments, at first near Lincoln and later near Bury St. Edmunds—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (May 14).

Lecturers and Assistant Lecturers (with research interests in inorganic chemistry, polymer chemistry or polymer physics) in Chemistry—The Registrar, Manchester College of Science and Technology, Manchester 1 (May 14).

Lecturers or Assistant Lecturers in Mathematics—The Registrar, The Manchester College of Science and Technology, Manchester 1 (May 14).

Research Assistant (qualified in biochemistry, physiology or zoology) to the Professor of Zoology—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (May 14).

Research Fellow in Electrophysiology in the Department of Experimental Psychiatry, to take part in research into the actions of drugs on the brain in experimental animals and eventually be responsible for the primate section of this programme—The Assistant Registrar, The Medical School, The University, Birmingham 15 (May 14).

Senior Lecturers in Metallurgy, Mathematics or Statistics, Pharmaceutical Microbiology, and Pharmacology; and Lecturers in Theoretical Chemistry, Mathematics and Pharmaceutics—The Bursar, College of Advanced Technology, Gosta Green, Birmingham 4, quoting "D" (May 14).

Assistant Lecturer in Organic Chemistry—The Secretary, The Queen's University, Belfast (May 16).

Assistants (3) (two in organic chemistry and one in inorganic chemistry) in the Department of Chemistry—The Secretary, The University, Aberdeen (May 20).

Tutorial Student in Mechanical Engineering—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 20).

Assistant in the Department of Natural Philosophy—The Secretary, The University, Edinburgh (May 21).

Assistant (medical graduate, preferably with a B.Sc. degree in physiology) in the Department of Physiology—The Secretary, University College, Earlsfort Terrace, Dublin (May 21).

Demonstrator in Agricultural Microbiology in the Department of Agricultural Sciences, School of Agriculture, Sutton Bonington, near Loughborough—The Registrar, The University, Nottingham (May 21).

Assistant Lecturer (with a good honours degree and preferably holding the degree of B.Sc.) in Geography—The Registrar, The University, Nottingham (May 23).

Lecturer (with qualifications in pure mathematics) in Mathematics—The Secretary, The University, 36 North Bailey, Durham (May 23).

Shell Students (graduates in chemistry or engineering) in Chemical Engineering—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 26)

Lecturer in Metallurgy—The Registrar, The University, Sheffield (May 28).

Lecturer (with a special interest in the philosophy of science) in Philosophy—The Registrar, The University, Hull (May 30).

Deputy (with experience of handling animals and preferably a zoological background) to the Director, Whipsnade Park, to assist the Director in the scientific and animal management work in the Park—The Secretary, Zoological Society of London, Regent's Park, London, N.W.1 (May 31).

Lecturer in Education; and a Lecturer in Geography in the Faculties of Arts and Economics, University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, May 31).

Lecturer in Geology with special reference to aspects of Economic Geology and, in particular, to the Geology of Coal and Oil—The Registrar, King's College (University of Durham), Newcastle upon Tyne 1 (May 31).

Senior Lecturer in the Department of Anatomy at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, May 31).

Lecturer in the Department of Fuel Technology and Chemical Engineering—The Registrar, The University, Sheffield (June 1).

University Lecturer or Demonstrator (with qualifications in chemical or mechanical engineering, physical chemistry or physics) in the Department of Chemical Engineering—The Secretary of the Appointments Committee, Department of Chemical Engineering, Pembroke Street, Cambridge (June 1).

Lecturer (with a qualification in biochemistry and preferably a medical qualification) in Chemical Pathology—The Dean, St Thomas's Hospital Medical School, London, S.E.1 (June 4).

Senior Tutor/Demonstrator in Physics at the University of Sydney, Australia—Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 4).

Lecturer (preferably with a medical degree) in Chemical Pathology at the University College of the West Indies—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (June 6).

Chair of Physics—The Registrar, The University, Birmingham 15 (June 15).

Clinical Lecturer (registered veterinary surgeon, preferably with an interest in obstetrics, infertility and in reproductive diseases) in Veterinary Practice—The Registrar, Trinity College, Dublin (June 20).

Scientific Assistant (with a biological degree, the ability to write correct English and preferably some knowledge of foreign languages), for work which includes the abstracting and reviewing of biological literature—The Director, Commonwealth Bureau of Plant Breeding and Genetics, School of Agriculture, Cambridge (June 25).

LECTURER (with special qualifications or experience in inorganic chemistry) IN INORGANIC CHEMISTRY at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, June 30).

LINCOLN PROFESSOR OF CLASSICAL ARCHÆOLOGY AND ART—The Registrar, University Registry, Oxford (June 30).

RESEARCH STUDENTS (2) IN HISTORY OR ARCHÆOLOGY at the British Institute of History and Archæology in East Africa, Dar es Salaam—The Secretary, British Academy, Burlington House, Piccadilly, London, W.1 (October 31).

ASSISTANT, Grade B, TO TEACH BIOLOGY AND CHEMISTRY to G.C.E. Advanced Level with some general science—The Principal, Peterborough Technical College, Eastfield Road, Peterborough.

BIOCHEMIST (Basic grade)—The Secretary, St. Helier Hospital, Carshalton, Surrey.

CHAIR OF PHYSICS; and a CHAIR OF BIOLOGY in the Royal University of Malta—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

CHEMIST or BIOCHEMIST (with a good honours degree in chemistry or biochemistry and preferably with postgraduate experience) IN THE RADIOBIOCHEMISTRY DEPARTMENT, for biochemical research involving the use of radioactive isotopes and in particular carbon-14 and tritium—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 60/3.

INSTRUCTORS or ASSISTANT PROFESSORS (well qualified candidates) IN THE DEPARTMENT OF CHEMISTRY—Prof. C. A. McDowell, Department of Chemistry, University of British Columbia, Vancouver 8, B.C., Canada.

LECTURER IN MATHEMATICS—The Registrar, Bradford Institute of Technology, Bradford 7.

MICROBIOLOGIST, to participate in research dealing with the origin, constitution and utilization of fossil fuels—The Secretary, Research Council of Alberta, 87th Avenue and 114th Street, Edmonton, Alberta, Canada.

PHYSICAL METALLURGISTS or PHYSICISTS (with research experience) IN THE PHYSICAL METALLURGY DIVISION, Department of Mines and Technical Surveys, Canada, to work with a group carrying out fundamental investigations in metal physics—Dept. M.T.S., National Employment Service of the Government of Canada, 61 Green Street, London, W.1.

PHYSICIST (basic grade)—The Secretary, Royal Free Hospital, Gray's Inn Road, London, W.C.1.

PRINCIPAL LECTURER IN NUMERICAL ANALYSIS, a SENIOR LECTURER IN STATISTICS, and an ASSISTANT LECTURER (Grade B) IN THE DEPARTMENT OF MATHEMATICS—The Principal, Welsh College of Advanced Technology, Cathays Park, Cardiff.

RESEARCH ASSISTANT (with a physics, mathematics or engineering degree, and interested in heat transfer and particularly in computational work in that field), for an original investigation into the transient temperature distribution in the rotors of steam turbines—Dr. R. D. Hoyle, Mechanical Engineering Department, City and Guilds College, Exhibition Road, London, S.W.7.

SCIENTIFIC OFFICER (with an honours degree in chemistry) at Northern Outfall Works, Beckton, London, E.6, for control, development and research—Medical Officer of Health (D.1/A), County Hall, London, S.E.1.

SENIOR GEOLOGIST (with a Ph.D. degree in sedimentary geology and an interest in stratigraphy) WITH THE PETROLEUM AND NATURAL GAS BRANCH of the Department of Mineral Resources, Regina, Saskatchewan, Canada, to prepare reports for publication on strata considered to have petroleum possibilities—The Agent-General for Saskatchewan, 19 Chester Mews, London, S.W.1.

SENIOR LABORATORY TECHNICIAN, to be responsible for the new physics teaching laboratories and lecture demonstrations up to degree standard—The Secretary, King's College, Strand, London, W.C.2, quoting Ref. 3072.

SCIENTIFIC RESEARCH IN THE OVERSEAS TERRITORIES OF THE BRITISH COMMONWEALTH

IN a recent book, "The End of Empire"[*], Mr. John Strachey argues cogently that Britain has a unique opportunity to lead the world in meeting the needs of the under-developed peoples and that, in doing so, in supplying both material means and technical skills, she can rise to a new level of national greatness. Mr. Strachey does not enter into any detail as to how this is to be done, and only passing reference is made to the Colombo Plan, the Colonial Development Corporation and the Colonial Development and Welfare Funds. Much stress is, however, laid on the replacement of the old conception of 'Colonial' by something wider, perhaps even wider than that of 'Commonwealth', though Mr. Strachey readily admits that the idea and the structure of the British Commonwealth offer possibilities of genuine advance.

From this point of view alone there is much to be said for the creation of the Overseas Research Council, though it is all the stranger that it should have been left for a question in the House of Commons to elicit the statement that the Colonial Research Council was dissolved in August 1959, and that its functions as an advisory and co-ordinating body now fall to the Overseas Research Council, which is responsible to the Minister for Science and operates in relation to overseas research generally. This was stated by Mr. Ian Macleod, Secretary of State for the Colonies, on March 10, and accordingly it would seem that "Colonial Research 1958–59"[†], which includes the report of the Colonial Research Council on Colonial research during the year 1958–59, along with the reports of the several specialist advisory bodies and one on research matters not covered by their reports, is the last to appear from the Colonial Research Council. Although, however, the covering letter submitting the report is dated November 4, 1959, no reference is made in any of these reports to the change, nor is any indication given as to the proposed future policy in regard to publication.

It would be difficult, however, to over-stress the importance of the work which has been briefly described in the reports collected under the general title "Colonial Research" during the past decade, and comments recently made by Dr. B. V. Bowden, principal of the Manchester College of Science and Technology, in two articles in *The Guardian* of March 9 and 10 dealing with his recent visit to Ghana, show how important it is both that such work should receive effective publicity and also that research work should be stimulated on an adequate scale in the university and technological institutions of the overseas territories before and after they achieve independent status. Dr. Bowden's articles show that the importance of research is as yet far from being understood in these emerging nations, or the contribution it can bring to the solution of their problems. The research schemes supported from Colonial Development and Welfare Funds and the research branch of the Overseas Civil Service may well increase rather than decrease in importance during the next decade.

The schemes noted in the present report—71 new schemes and 63 supplementary—involve grants totalling £798,974 and bring the total allotted to Colonial Development and Welfare Research Schemes since 1940 to £19,493,932; actual disbursements now total nearly £14·7 million. Much the largest research schemes approved during the year ended March 31, 1959, are those for the Tropical Section of the Road Research Laboratory (£121,568), the Colonial Pesticides Research Unit, Arusha, East Africa (£71,188) and the maintenance of the Anti-Locust Research Centre, 1958–59 (£65,657); £31,405 was for trachoma research, 1958–60; £23,372 for the Desert Locust Survey; £39,524 for the Tropical Metabolism Research Unit, Jamaica; £22,728 for agricultural research in Swaziland; some £31,000 for the West African Building Research Unit; £19,440 for the Colonial Microbiological Research Institute, Trinidad; £20,226 for the Seismic Research Unit in the Imperial College of Tropical Agriculture, Trinidad; £15,825 for the establishment of a cocoa research station in the British Solomon Islands Protectorate; and £15,000 for sorghum breeding research in East Africa. While no other research grants exceeded £15,000, these examples sufficiently indicate the vital importance of continued support from the United Kingdom, both in respect of the nature of the schemes and the financial resources of the territories concerned, even when due regard is had to the assistance already given by the Colonial governments from their own resources.

It is obvious from these figures that the research schemes represent a relatively minor proportion of the assistance already being given to the lesser developed countries from British Government funds. The White Paper "Assistance from the United Kingdom for Overseas Development"[*] put the total at £138 millions in the current year alone, an increase of £57 million on 1957–58, and although the former sum represents about 1·25 per cent of the national income of the United Kingdom, the White Paper urges the need to continue and if possible increase this effort. It may well be that the proportion going to research schemes is the one that, apart from educational assistance, most urgently needs increasing and, as already suggested, the need may become even more urgent as the Colonial territories achieve independence. About 33 per cent of the gross allocation of Colonial Development and Welfare Research Funds has been for agricultural, animal health and forestry schemes, 17 per cent for medical research, 9 per cent for fisheries research, 10 per cent for tsetse and trypanosomiasis research, 8 per cent for social science and economic research, 9 per cent for pesticides research, 5 per cent for research sponsored by the Colonial Products Council and 3 per cent for anti-locust research. Frequently such research involves the co-operation of research institutions and organizations working in several territories, and it may not be easy for a newly independent territory always to appreciate the significance of such work or the factors determining its success. A similar observation might be made of some of the work described in the section of "Colonial Research" which deals with research matters not covered by the reports of the specialist advising bodies. Building and housing research, for example, largely relies on the work of the Tropical Building Section of the Building Research Station of the Department of Scientific and Industrial Research in Britain. The Geodetic and Topographical Surveys and the Geological Surveys as well as meteorological research also depend largely on assistance from the United Kingdom, and although in East Africa there is a flourishing Industrial Research Organization, elsewhere the Crown Agents' Engineering Advisory Service assists and advises overseas officers on a wide range of technical matters; reference is also made particularly to advice given overseas by the Water Pollution Research Laboratory.

In much of this work man-power is an important factor. Twenty-five new appointments brought the total complement of the Research Branch of the Overseas Civil Service to 207 in March 1959. There was also a Research Fellow studying nematode damage on East Africa crops, who completed his investigations during the year, and a second continuing work on human trypanosomiasis at the West African Institute for Trypanosomiasis Research; two further Research Fellowships were awarded for work at the University College of the West Indies as well as two research studentships in medicine and one in soil science for training for research appointments overseas.

Measured against the tasks still to be undertaken, let alone completed, this man-power seems slender even when allowance is made for the substantial contribution made by British universities and the staffs responsible to the several research councils such as the Council for Scientific and Industrial Research, the Medical Research Council and the Agricultural Research Council. The question of man-power is undoubtedly one of the most important which the Overseas Research Council will have to face, and it should be able to count on the full support of the Advisory Council for Scientific Policy, perhaps the more especially since the recent inquiry into scientific and engineering man-power in Great Britain conducted for that Council by its Committee on Scientific Man-power made no estimates of the demand for such man-power overseas. The proceedings of the Commonwealth Education Conference again show how important it is that the overseas need should receive full attention in planning the expansion of university and of technological education.

In this context the new Overseas Research Council will require to work in close association with the Scientific Council for Africa South of the Sahara and with the Commission for Technical Co-operation in Africa South of the Sahara. The recently published report of the tenth meeting of the Scientific Council* gives no indication of the resources at the disposal of either the Council or the Commission; but, quite apart from the extent to which many problems in Africa depend on international co-operation for their solution, it is obvious that every effort should be made to avoid duplication of effort, and to use the limited resources of scientific and technical man-power as wisely as possible and where the maximum advantage to the general benefit can be obtained. Reference is already being made to the increasing difficulty in co-ordinating agricultural research projects, for example, owing to the speed of developments in Africa, and only international action can hope to solve the problems raised by the destruction of natural resources in Africa.

There are indeed signs that co-operation is developing. An Inter-African Conference on hydrology is to be held at Nairobi in January 1961, and the Inter-African Pedological Service, which was expected to be fully staffed by the autumn of 1959, reports progress with the pedological map of Africa except in West Africa. The Inter-African Soils Bureau is directing its activities more towards liaison between technical organizations working in Africa and is seeking to play a more dynamic part. Inter-African Conferences on Soils and on Forestry have already been held, and the Food and Agriculture Organization of the United Nations intends to set up in Africa a regional forestry commission as in other continents. Other examples are to be seen in the Inter-African Bureau for Epizootic Diseases, the function of which in examining requests for technical aid in the field of animal diseases is likely to develop in future, the Inter-African Conferences on Housing and Urbanization and on Labour, of which two and six, respectively, have already been held, and the Inter-African Committee on Maps and Surveys.

One note of caution should be sounded in respect of any developments depending on the Scientific Council for Africa South of the Sahara. Among the participants are the Union of South Africa, which indeed supplies the present chairman in the person of

---

* Scientific Council for Africa South of the Sahara. Publication No. 37: Tenth Meeting of the Science Council, Kampala, 1959. Pp. 135. (London: Secretariat, C.C.T.A./C.S.A., Abbey House, Victoria Street, 1959.)

Dr. P. S. du Toit, and Dr. S. M. Naudé as an ordinary member. Recent events in South Africa and the general policy of the South African Government must make it more than doubtful whether the continued support of that Government can be expected, and even whether its membership of the Council will continue to be acceptable to other countries. The ultimate effect of the South African Government's policies towards the universities and eventually to scientific research is likely to stultify the value of much of its contribution.

The picture of co-operation provided in "Colonial Research 1958–59" is much more reassuring. Much the longest of the reports of the ten specialist advisory bodies is that of the Committee for Agricultural, Animal Health and Forestry Research, which occupies more than 170 pages out of a total of 419. Besides stressing the importance of the work being done by the Commonwealth Institute of Entomology, the Commonwealth Institute of Biological Control, the Commonwealth Mycological Institute and the Department of Statistics at the Rothamsted Experimental Station, this report deals at length with the work of various regional organizations such as the East Africa Agriculture and Forestry Research Organization, the East Africa Veterinary Research Organization and the West African Cocoa Research Institute. The much shorter reports of the Colonial Fisheries Advisory Committee and the Colonial Social Science Research Council are likewise much concerned with the work of regional bodies. But the report of the Colonial Pesticides Research Committee, by and large, depends on the work of such co-operative ventures as the Colonial Pesticides Research Unit at Porton, the Agricultural Research Council's Unit of Experimental Agronomy at Oxford, the Silwood Park Field Station of the Imperial College of Science and Technology, the Colonial Pesticides Research Unit, East Africa, and the West African Fungicides Team.

The bulk of the work of the Tsetse Fly and Trypanosomiasis Committee is carried out through the East African Trypanosomiasis Research Organization and the West African Institute for Trypanosomiasis Research, while that of the Anti-Locust Research Centre on locust research and control is peculiarly dependent on political factors which may retard or favour international co-operation. This year's report refers to a notable tendency to expand and strengthen international co-operation both in locust control and in these lines of research which provide a basis for practical anti-locust measures. The Director refers appreciatively both to the help given by the Food and Agriculture Organization, the United Nations Educational, Scientific and Cultural Organization and the World Medical Organization, and to progress made in research on problems of locust biology.

In such conditions it is impossible for scientific and technical research on problems of the Colonial or Overseas Territories to disregard entirely the political situation, at least so far as it affects the conditions in which scientific and technical work is pursued. It would indeed be wrong if scientists and technologists failed to make representations when particular policies threaten the conditions in which creative work, effective co-operation between scientists and technologists of different nationalities or races, or the free interchange of scientific and technical knowledge, are possible. "Colonial Research 1958–59" provides an impressive picture of the effort which is already being made in Great Britain to serve the Overseas Territories, whether dependent or independent. But there is no room for complacency; expansion is an urgent need. It is the more important, therefore, that the political conditions which determine its efficiency and effectiveness should be clearly understood, and that government policies should be such as to encourage and not hinder or frustrate the essential co-operation and the creative work which have so much to bring to the welfare and development of the less advanced peoples.

MODERN PHILOSOPHY OF SCIENCE

Modern Philosophy of Science

Selected Essays. By Hans Reichenbach. Translated and edited by Maria Reichenbach. Pp. ix+214. (London: Routledge and Kegan Paul, Ltd.; New York: Humanities Press, 1959.) 28*s*. net.

THIS book contains eight articles by the late Prof. Hans Reichenbach, only one of which has previously appeared in English. Five are translated from earlier appearances in German, and two, concerned with the ethical problem, are compiled from MS. notes left by the author. The translation and editing have been carried out by the author's widow, Mrs. Maria Reichenbach, and there is a short foreword by Prof. R. Carnap. A valuable feature of the book is a complete bibliography of Reichenbach's writings which is appended.

Reichenbach was one of the founders of the logical-empiricist school of philosophy which came into being mainly through the philosophical implications of the theory of relativity, and throughout his life he remained one of its ablest and clearest expositors. Anything from his pen is worth reading. Nevertheless, it is doubtful whether the present volume was a well-advised venture. Much of the material has been incorporated in better form in work published by Reichenbach during his lifetime, and some of the remainder—particularly the first essay, which replies to some early objections to relativity—is no longer of vital interest. The immediate philosophical reaction to the relativity theory was the charge that it violated certain fundamental philosophical principles and therefore could not be true. This is now generally acknowledged to have been due to a misunderstanding. It is clear that, so far as such principles are concerned, the theory could be true: the important question now is whether it is true. The criticisms which Reichenbach set out to answer in 1921 have long ceased to trouble anyone.

The essay on "The Freedom of the Will", together with a short note on "The Explication of Ethical Utterances", constitute the part of the book not previously published. This was well worth issuing, for it presents in more detailed form ideas already adumbrated in "The Rise of Scientific Philosophy", published in 1951. The thesis maintained is that while determinism excludes complete freedom of the will, probabilistic causality does not, and a "non-cognitive theory of ethics" is advanced of which the essence is "the recognition of the non-logical relation between knowledge and action". This is consistent with the author's general philosophy of science, of which "The Rise of Scientific Philosophy" gives an admirable account. Owing to the much more speculative nature of the subject, however, it is scarcely likely to carry the same conviction as the epistemological discussions which are more directly related to the actual content of modern physical theory.

HERBERT DINGLE

SOCIOLOGY: THE NEW HOPE

The Sociological Imagination

By C. Wright Mills. Pp. vii+234. (London and New York: Oxford University Press, 1959.) 36*s*. net.

THIS book has, in effect, three themes: (1) a sociological account of the present state of the social sciences themselves, and particularly of the state of sociology in the United States; (2) recommendations concerning what the social sciences should be like, and finally, (3) reflexions on our times. The three themes are, of course, closely interwoven, for the account of current sociology is largely a condemnation which calls for a specification of a better way, while the diagnosis of how the ills came about requires a discussion of the wider social factors responsible for them.

At the root of sociology and the social sciences lies a great hope and a promise—of a kind of collective self-knowledge. If there is one thing which ought to be obvious (though there are still people to whom it is not) it is that society constrains us, that our lives, thoughts and aims are, at the very least, conditioned by a social framework we never made or chose, and in a way we often do not understand. Sometimes, and for those fortunate enough to be in a congenial environment, this is no source of sorrow: but when the insight is combined with a partial rejection or failure of current values and institutions, it leads to a hope of control through knowledge. This hope, as Prof. Mills reminds us, was at the origin of sociology, and it still powerfully animates him—if not all his colleagues.

If there is one country where this hope might be thought to have better expectations of fulfilment than elsewhere, it is the United States, where sociology is a recognized and extensive profession, where it is neither muzzled (as it is behind the Iron Curtain), nor ignored as the dubious fad of a marginal minority. In fact, the picture in the United States is not at all rosy, despite the number of sociologists and the recognition they receive. Prof. Mills provides an explanation, and he does it brilliantly.

A good deal of the output of the flourishing American sociological profession consists, using Mills's terms, of "Grand Theory" or of "Abstracted Empiricism". "Grand Theory", not to put too fine a point on it, is simply pretentious verbiage of a kind which has to be read to be believed. Prof. Mills charitably says that it does contain some ideas, and heroically extracts them for us. The respectable mice rescued from under the mountains of rubbish are insights—valid so far as they go and well suited for any systematic treatment of societies—such as that social life consists of the interaction of individuals with reasonably stable reciprocal expectations, with shared values which had been inculcated by a common background, and so forth . . . (but not for very long, for this is nearly all there is in it).

"Abstracted Empiricism" consists of the proliferation of ritualized, standardized surveys, usually by means of questionnaires, in which the collection of dubiously valuable or even reliable data is guided by little thought or concern with genuine questions. The blindness of such "Abstracted Empiricism" complements the emptiness of "Grand Theory".

Prof. Mills gives us a convincing account of how these fashions came to be dominant. Their roots are various: the emulation of a false image of natural science, an image which was mistaken anyway, and which in any case, even if it were valid, could not be easily re-applied to social matters; the shift of the practical impulse from, roughly speaking, helping the poor to helping sales promotion and the manipulation of personnel; the safe political innocuousness of the new practices; the (probably inevitable) bureaucratic ethos inherent in the administration of foundations, expensive and large-scale research, etc. (Natural scientists are fortunate in that the traditions of their subject were well established before our present era. One shudders to think what might have happened had the foundations existed in the early days of the Royal Society.)

Prof. Mills attempts to do more than describe and analyse the current ills, he also hopes to remedy them. His recommendations to sociologists are sound and perceptive. So are his reflexions on our times and the part that thought and valuation can play in the modern world. I only fear that he may implicitly —in trying to stem the tide—be too optimistic, that the general social factors on the other side are too strong. I hope I am wrong.

But this is not a book which will stand or fall by either the soundness or the success of its positive recommendations. It is already fully justified by the admirable account offered of an important if unattractive phenomenon, and one which is playing a very significant part in American life. This was, so to speak, a necessary book. Somebody had to write it, and we can all be thoroughly grateful that the somebody was Prof. C. Wright Mills.

E. GELLNER

DAIRYING IN GREAT BRITAIN

The United Kingdom Dairy Industry

Edited by Prof. E. L. Crossley. (Prepared under the auspices of the XV International Dairy Congress on behalf of the United Kingdom Dairy Association.) Pp. viii+142+16 plates. (London: United Kingdom Dairy Association, 1959.)

THIS book was written to mark the fifteenth International Dairy Congress held in London during the summer of 1959; it provides a valuable picture of the state of the dairy industry in the late fifties. Prof. E. L. Crossley, helped by a list of distinguished contributors, has distilled 142 remarkably uncluttered pages of useful information. He begins by setting dairying in relation to other branches of agriculture and reminds us that milk and dairy products worth no less than £350 million are produced annually on British farms. This forms about one-third of the total agricultural output and represents almost twice as much milk as was produced for sale in 1935, or is produced at the present time in such major dairying countries as Denmark, the Netherlands and New Zealand. Further, the annual increase in milk production has also been considerably more rapid than in most other dairying countries.

From the economic structure of the industry we pass to milk production on the farm and the astonishing changes which have taken place since 1935 in the national herd, in milk recording, in artificial insemination, in the feeding and management of cows and in the design and use of cowsheds and milking machines. Nor are the advisory services, the necessary milk regulations and the means of controlling milk quality overlooked.

About two-thirds of the book is devoted to dairying in its narrower sense, to milk collection, transport and reception, to pasteurization, sterilization and bottling of milk, with all the machinery these involve to-day, to some essentially British aspects of milk distribution and to the control of milk quality at every stage. Naturally we find also an account of the development of a highly efficient dairy technology from the traditional farm-house manufacture of cream, butter and cheese.

The book concludes with chapters describing the training of young people for the dairy industry and outlining the work now in progress at the main centres of research. For readers who find here a new or wider interest in dairying—and they will certainly number more than the overseas Congress visitors at whom the book was modestly aimed—there is a useful list of general information. This provides a ready means of following any topic in greater detail. There is also an abundance of good illustrations ranging appropriately from attractive coloured drawings of the breeds of dairy cattle to most appetizing pictures in beautiful colour of the industry's greatest triumph, British territorial cheeses at their best.

C. C. Balch

CENTRAL AFRICAN SAVANNAHS

Les Savanes de l'Afrique Centrale

Essai sur la Physionomie, la Structure et le Dynamisme des Formations Végétales Ligneuses des Régions Sèches de la République Centrafricaine. Par Roger Sillans. (Encyclopédie Biologique, Tome 55.) Pp. xv+424+2 planches. (Paris: Éditions Paul Lechevalier, 1959.) 16,000 francs.

In spite of the wider geographical implications of the title, this book relates directly only to the territory of Oubangui-Chari, which with the Cameroons and Moyen Congo to its west, and the Sudan to its east, is, from its central position in tropical Africa, of more than usual importance for considering questions of plant-geography. Based on a doctoral thesis by R. Sillans, it is primarily a record of personal observation and study of the savannahs of that part of Africa, and more especially of their woody vegetation.

The contents of this book follow an arrangement not unusual in studies such as these, with descriptions of climate, geography, geology and soils, and a general account of the ecological classification of the vegetation of Oubangui-Chari, followed by a discussion of the methods employed by the author and some of the terms used. After this preliminary matter there is a much more detailed account of the savannah vegetation, together with a floristic list of the known woody species.

The territory shows a range of vegetation from lowland rain-forest to woodland and savannah, spread over a rather uniform topography, and accompanied by gradual climatic changes. As the author suggests, there are no natural frontiers to the territory. In all, some 3,600 species occur, among which are a number of endemics of which the author gives a list. This, however, needs some revision: for example, *Cola gigantea* is not endemic, and the remarkable Bignoniaceous genus *Tisserantodendron* occurs also in the Cameroons. The author also attempts to give a biological spectrum of the flora.

That part of the work of most general interest deals with the author's conclusions about how the vegetation has evolved. He maintains that the original covering of forest or woodland has been and is still being destroyed by means of clearing for the purpose of subsequent cultivation. Repeated through the centuries, this clearing, accompanied by partial or complete felling and by firing of the resultant débris, has entailed modifications in vegetation, species, soil and, perhaps, climate. The forest is replaced by tall grassland with more or less scattered trees, which may itself develop into savannah-woodland and ultimately, perhaps, again into forest. The savannahs of Oubangui-Chari in fact represent, according to the author, various stages in seral regeneration following cultivation.

Now, according to Sillans, the original regression of the forest is in no way due to bush-fires; not until cultivation has resulted in the establishment of grassland can they enter. He considers that their destructive effect has been over-estimated, and that they do not normally prevent a gradual re-development of savannah woodland into forest. No evidence of real adaptation of plants to a permanent régime of fires is regarded by him as proved; but there is an interesting account of nanism and the 'suffruticose' habit being induced in a species of *Bridelia* through repeated cutting in connexion with cultivation.

The problems of the age and origin of bush-fires and their effect on the savannah vegetation of tropical Africa are still most disputed; in fact Prof. J.-L. Trochain, in a preface to the book, combats some of M. Sillans's views. The ultimate solutions are, however, brought nearer by the important evidence presented in this work. I am, however, appalled by its price of 16,000 francs.

J. P. M. Brenan

UNSTEADY SUPERSONIC FLOW

The Potential Theory of Unsteady Supersonic Flow

By Prof. John W. Miles. (Cambridge Monographs on Mechanics and Applied Mathematics.) Pp. xii+220. (Cambridge: At the University Press, 1959.) 45*s*. net.

The aerodynamic theory of unsteady flows is mainly concerned with questions of the following type: If a wing or body, moving forward with constant speed, has a prescribed transverse motion about its rectilinear mean path, what are the resulting forces and moments? During the golden age of the linearized theory of compressible flow (1945–55 approximately), when it was permissible to assume that wings were thin, Mach numbers moderate, and disturbances small, a considerable store of answers to such questions was established. Prof. Miles was very much in the forefront of the attack on these problems, and the appearance of his authoritative book on the subject is to be welcomed.

The book deals mainly with the supersonic theory, in which the existence of domains of influence and dependence makes it possible to solve explicitly a number of linearized problems. The opening chapter is a careful study of the restrictions appropriate to various approximate governing equations, of which that corresponding to the sound equation in still air is the most important: various xt-transformations (x is the streamwise co-ordinate, t the time) of this equation are then considered. Basing his presentation not on the traditional method of retarded-potential doublets but on the more compact method of integral transforms, Prof. Miles makes short work of each of the following problems: two-dimensional wings, the rectangular wing of semi-infinite span, wings with 'supersonic' edges, and the extension of Evvard's method to wings with straight, subsonic side-edges. For the delta wing with subsonic edges, further approximations are necessary. There is a detailed account of methods for wings of slender planform and slender bodies, and the book ends with a genuflexion towards non-linear problems.

Despite the formidable economy of his presentation, the author cannot treat all the ramifications of his subject in a book of modest size, but there are ample references to papers on those (mainly secondary) questions which are not included. The book maintains the high standard of the Cambridge Monographs on Mechanics and Applied Mathematics.

L. E. FRAENKEL

MONKEYS AND DISEASE

Diseases of Laboratory Primates

By Prof. Theodore C. Ruch. Pp. xxvi+600. (Philadelphia and London: W. B. Saunders Company, 1959.) 52*s*. 6*d*.

THIS volume is the first of four parts of a projected "Handbook of Primates", and treats in monographic form the spontaneous diseases of laboratory primates. The main topics reviewed are the diseases caused by parasitic agents and, to a lesser extent, nutritional disorders, both of which have an important bearing on the management of a monkey colony. In addition to this information, which is of immediate practical value, the author also describes the nature of conditions such as cardiovascular and dental diseases and suggests that monkeys may be suitable animals for research into these problems.

Three of the more important conditions—enteric diseases, respiratory tract infections and tuberculosis—which are responsible for the high mortality frequently observed in monkeys, are dealt with at length. The chapters on these subjects will be of particular interest to those who are responsible for the management of large colonies of monkeys now maintained in many countries for the production and testing of poliomyelitis vaccine.

In the course of reading this book, attention is directed to the numerous pathogenic agents which have been accidentally transmitted to man. Of these the most serious is *B*-virus (*Herpesvirus simiae*), which has caused a number of fatal cases of ascending myelitis. Since this virus, and other pathogenic agents, are localized in the mouths of infected animals, the author rightly points out that procedures should be designed to preclude, so far as possible, the occurrence of monkey bites. It would have been of value to those who have not seen this condition in monkeys if photographs showing *B*-virus lesions in infected animals had been included.

The compilation of this volume is clearly the result of much painstaking work involving an extensive review of literature and, in addition to providing factual material, Prof. Ruch has succeeded in presenting the subject-matter on each topic in a most readable form. This will be a very useful reference book and its publication fills an important gap in scientific literature.

C. R. COID

THE MEASUREMENT OF INFORMATION

Information Theory and Statistics

By Prof. Solomon Kullback. (Wiley Publications in Mathematical Statistics.) Pp. xvii+395. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 100*s*. net.

THIS book provides a treatise upon the general statistical theory of information, as complete, thorough and up to date as any single book to-day. It deals with the various measures of information and information-rate, not restricted to their place within the theory of communication (as are so many recent texts), but as part of the general theory of statistics and probability. It covers and relates the work of Fisher, Shannon, Chernoff, Kolmogorov, of Good, Woodward, Barnard and many others well known within the field.

The author's reputation here needs no comment from me. In this book he aims at unification—conceptual, notational and methodological—of scattered work by West Europeans, Americans and Russians too. He covers not only the specialized applications of information theory to communication problems but treats the whole field of statistical hypothesis testing as it arises also in the design of experiments and in observation theory, in the theory of stochastic processes, in parameter estimation and in other processes of statistical inference. In the first half of the book the various logarithmic measures of information are developed and their properties studied, in terms of measure theory; it is the second half which is concerned with a wide range of applications to statistical inference.

The book is essentially mathematical in treatment and in its purpose. It comes at an opportune time for many people in the physical sciences; for biologists, for telecommunication engineers (detection, coding problems, etc.); again, for psycho-physics (behaviour models and artefacts) and many other fields. Modern techniques of statistical inference are making an ever-increasing contribution and the relevance of information theory merits careful attention and revaluation at this present time.

The many worked and unworked examples form a particularly valuable feature of the book; it is well provided, too, with a glossary of mathematical terms and with a comprehensive bibliography of several hundred references.

COLIN CHERRY

Rice

By D. H. Grist. Third edition. (Tropical Agriculture Series.) Pp. xxiii+466+72 photographs. (London: Longmans, Green and Co., Ltd., 1959.) 48*s*. net.

D. H. GRIST'S valuable book "Rice" is now in its third edition. It has been strengthened by the inclusion of two authoritative chapters, one on the genetics of rice and the other on improvement by selection and breeding. These were contributed by D. Rhind, who has had the satisfaction of seeing in West Africa progeny of seed he bred in Burma. Grist also has spent much of his life in the study of this crop and is to be congratulated both on the original compilation and on the no less important revision. In Chapter 12, Grist quotes the work of Pearsall and Mortimer (*J. Ecol.*, 27, 483; 1939) and of Pearsall (*Emp. J. Exp. Agric.*, 18, 289; 1950) which, he points out, provided an entirely new approach to the chemistry of water-logged soils. The Japanese quickly followed up these ideas, leading to more efficient use of their hard-pressed paddy fields. It is hoped that it will be possible for Grist to enlarge this chapter in the next edition of this book so as to include an account of this recent work.

H. GREENE

1959 Supplement to British Veterinary Codex 1953

Pp. xviii+134. (London: Pharmaceutical Press, 1959.) 35*s*.

THE appearance of this Supplement to the British Veterinary Codex is an expression of the policy of the Codex Committee to provide an interim volume before proceeding to a full new edition. It is a sound policy, and a necessary one, if the Codex is to attempt to keep abreast of new developments in the field of pharmacology. The drugs and vaccines described in the Supplement are already familiar by their having been some time in veterinary use, and it becomes a welcome reference book on actions and dosage. The period since the first appearance of the British Veterinary Codex in 1953 has been one of intensive research in pharmacology, and it is, indeed, during this period that a specific discipline of veterinary pharmacology has emerged. Curiously enough, despite these exciting new developments, the teachers of veterinary pharmacology in Britain are only now beginning to turn to the problem of producing a text-book in their subject to which the student or practitioner can refer. In this situation the Codex is particularly valuable.

P. JEWELL

Brompton Hospital Reports

Vol. 27, 1958. (A collection of Papers by Members of the Staffs of the Hospitals for Diseases of the Chest (Brompton Hospital and London Chest Hospital); and of the Institute of Diseases of the Chest.) Pp. x+277. (London: Lloyd-Luke (Medical Books), Ltd., 1959.) 15*s*. net.

FOR those who wish to follow the progress of knowledge of diseases of the chest this volume collects, in the handy and attractive form well known to readers of the earlier volumes in this series, twenty-one papers, all of which have been previously published in the journals named in the preface.

The volume opens with an appreciation of the fine work of Maurice Myers, who joined the staff of the Brompton Hospital Sanatorium in 1932 and spent the rest of his professional life there, being deputy medical superintendent for the greater part of this time. For him, as this memoir of his life says, the treatment of pulmonary tuberculosis was an art, and his death in December 1958 deprived us of the services of a man of long and wide experience.

It is impossible, in a brief notice, to discuss in detail the contents of the papers here reproduced. Three of them deal with the treatment of pulmonary tuberculosis by extraperiosteal plombage, thoracoplasty and streptomycin, isoniazid and sodium *p*-aminosalicylate. Two papers report respectively on the treatment of pleural effusions by antibacterial therapy and on the proteins in serum and the pleural fluid, while two discuss studies of tuberculin sensitivity in tissue cultures and in the middle-aged and the elderly. There are five papers on heart conditions, one on multiple brochostenoses due to sarcoidosis, one on pleural neoplasms and one on the surgery of œsophageal lesions. The volume concludes with four papers on bronchiectasis, bronchodilator drugs and bronchograms, and two on pulmonary mycoses in Britain and the occurrence of *Aspergillus fumigatus*. The list of papers published by the staff during August 1957–July 1958, and the author and subject indexes to volumes 1–27, summarize the great work that this hospital has been doing.

G. LAPAGE

Genetyka

By Edmund Malinowski. Pp. 582+14 plates. (Warszawa: Państwowe Wydawnictwo Naukowe, 1958.) Cena zl. 42.

THIS text-book on genetics by one of Poland's leading authorities on the subject follows the familiar lines of such books published in Western Europe in pre-war times. The reader is introduced to the principles of evolution through references to Darwin; the story of Mendel's discovery, and the rediscovery of Mendel, is retold and the now classical studies of the early Mendelians are described. The role of the chromosomes in heredity and in evolution is explained, and brief references are made to some of the more recent genetical studies such as those on biochemical mutants in micro-organisms and the Watson–Crick views on the structure of deoxyribonucleic acid.

The chapter on evolution contains a brief section on Lamarck and the inheritance of acquired characters; experiments of MacDougall, Harrison and others are shown to be susceptible of explanation as selection effects and the cautious conclusion is reached that there is no evidence so far that can be accepted as definite proof of the inheritance of acquired characters. There is no mention of the work of T. D. Lysenko and his school.

In the final chapter on the application of genetics in agriculture we are told that the main achievements in breeding improved wheat varieties for Polish conditions have been based on some original crosses between the English wheat Squarehead and the Polish Pulawka. Mention is made of the production of hybrid maize and hybrid onions in the United States and of the artificial production of polyploid races of various crop plants in Sweden and elsewhere. In this connexion we are told of some tetraploids of serradella (*Ornithopus sativus*), produced by Polish workers, which exceed the original diploid strains in fodder yield by as much as 100 per cent.

P. S. HUDSON

EXISTENCE OF NET ELECTRIC CHARGES ON STARS

By Prof. V. A. BAILEY
School of Physics, University of Sydney

I

It has been found possible to account for the known orders of magnitude of five different astronomical phenomena and the directions relating to three of them by means of the single hypothesis that a star like the Sun of mass M_s gm. carries a net negative charge, $-Q_s$, which is given by the formula:

$$Q_s = \beta_s G^{\frac{1}{2}} M_s \text{ e.s.u.} \qquad (1)$$

where G is the constant of gravitation and β_s is a pure number of the order of 0·03.

Thus, for the Sun we have:

$$Q_s = 1{\cdot}5 \times 10^{18} \text{ e.s.u.} \qquad (2)$$

The same hypothesis leads to simple qualitative or semi-quantitative explanations of at least the thirteen other phenomena considered later.

The first five phenomena are as follow: (1) the magnetization of the Earth; (2) the outer Van Allen belt of radiation; (3) the maximum energy of about 5×10^{18} eV. found for a primary cosmic ray particle; (4) the Sun's north polar magnetic field vector H_p; (5) the approximate equality of the ratio P/U for the Sun to the mean value of this ratio for Blackett's[1] group of five magnetic stars, where P is the magnetic moment and U is the angular momentum of a star.

The phenomena 1–4 arise as follows from the presence of the solar charge $-1{\cdot}5 \times 10^{18}$.

The velocity of translation of the Sun relative to the Earth is $v_s = -29{\cdot}8$ km./sec. and consequently its charge, $-Q_s$, sets up in a non-rotating frame of reference accompanying the Earth a magnetic field H_r which is perpendicular to the ecliptic, directed from north to south and has near the Earth the intensity $6{\cdot}9 \times 10^{-3}$ gauss.

The magnitude and direction of H_r are approximately those required by J. S. Chatterjee[2] for the initial field, of unknown source, which saturates the highly permeable magnetic material of a 20-km. shell near the top of the Earth's crust and thus imparts to the Earth its observed magnetization. For Chatterjee requires a "field of the order of 0·1 to 0·01 gauss".

Moreover, the field H_r not only magnetizes the Earth but also neutralizes the resulting external terrestrial field in a narrow and approximately toroidal region which lies nearly in the Earth's equatorial plane and has a radius equal to about 3·7 earth radii. The magnetic field in and near this region is such that it could act as a 'magnetic bottle' which is partly accessible to energetic charged particles from much further out. These results account very well for the existence of the outer Van Allen belt which has a maximum density at about 3·6 Earth radii.

The Sun's charge also produces an electric field which has the potential $V = -3{\cdot}0 \times 10^{17}$ volts at the Earth's orbit. This field causes free protons and other nuclei in distant space to approach the Sun and move in orbits round it. Those nuclei which lose little energy on the way to the Earth's orbit will then reach this orbit with an energy of $3{\cdot}0 \times 10^{17}Z$ eV., where Ze is the charge on the nuclei concerned. For an iron nucleus this energy amounts to 8×10^{18} eV. Also the orbits of all the nuclei will be oriented at random. These results account very well for the observed maximum energy 5×10^{18} eV. of a primary cosmic ray particle and for the isotropy of cosmic rays.

The rotation of the negatively charged Sun imparts to it a magnetic moment which is directed from north to south. This in turn produces a north polar magnetic field vector H_p which would have the magnitude $-0{\cdot}75$ gauss if the Sun's charge were distributed in the same way as the mass and if the mass and angular velocity were distributed as in Chapman's[3] model A. A uniform distribution of Q_s throughout the Sun would yield the value $-8{\cdot}5$ gauss. These results agree in order of magnitude and direction with the observations of Hale and Langer who, according to a report by H. W. Babcock[4], found a mean value of -4 gauss. They also agree with the most recent observations of H. D. Babcock[5]. The presumably temporary reversal of the direction of H_p, during six years, which was observed by the Babcocks suggests that our estimated value of H_p corresponds to the constant component of the Sun's magnetic field, and that there exist also an oscillating component which varies with the solar cycle and a component due to local turbulence.

The fact (5) would arise from the hypothetical stellar charges specified by formula (1) if the Sun and the average of Blackett's five stars had axially symmetrical distributions of the angular velocity ω, the charge density σ and the mass density ρ such that at a point (r, θ) the quantities $\omega\sigma$ and $\omega\rho$ are each functions of θ and r/a alone, where a is the diameter of the star. The latter assumption is the reasonable one that magnetic stars are homologous rotating bodies.

It would be a remarkable coincidence if these five phenomena were all explained correctly in their orders of magnitude and their related directions by means of a single hypothesis which is entirely false, even if the last phenomenon calls for a supplementary assumption of homology in magnetic stars.

For, even if we make the moderate assumption that the probability of a false theoretical value A, of a physical quantity, agreeing in order of magnitude with the observed value B is less than 0·1, the probability of five such agreements and of three chance agreements of direction would be less than $1/10^4 \times 2^3$, that is, less than 1 in 80,000.

If to these eight agreements we add the thirteen other different phenomena which are qualitatively or semi-quantitatively explained below by means of the same 'false' hypothesis, the resulting coincidence would be truly extraordinary.

My hypothesis implies the existence of strong electric fields (but less than 10^9 V./cm.) in the Sun's atmosphere. In combination with the magnetic fields which exist there they could lead to relativistic electrons trapped in the corona. Three consequences of this situation are: (a) the phenomena cited by Kellogg and Ney[6] in support of their new theory of the corona; (b) the high temperatures in the corona; (c) the acceleration and ejection of fast magnetized and negatively charged clouds of ionized hydrogen, of the same general character as Bostick's plasmoids and rings, which are generated along with flares near strongly magnetized regions like sunspot groups.

These fast clouds could serve to explain the solar radio phenomena associated with flares observed by Wild *et al.*[7] and interpreted by them and by McLean[8] as indicating the early ejection of a fast stream of electrons with a mean velocity of about $\frac{1}{3}$ c, and the subsequent ejection of a cloud of relativistic electrons at velocities of about 1,000 km./sec., that is, $c/300$. They estimate that the fast stream contains not less than 3×10^{33} electrons.

If we assumed that this stream diverges less than π steradians it would follow that at least 7×10^{25} electrons are intercepted by a sphere around the Earth of radius equal to that of the outer Van Allen belt. Consequently the intercepted electrons would tend to become trapped in the Van Allen belt and so to lower the Earth's potential by more than $4 \cdot 5 \times 10^{9}$ V. This would lead to a large transient increase in the intensity of the cosmic rays and also allow the entry into the Earth's upper atmosphere of a large flux of low-energy nuclei. The latter flux could be held responsible for the remarkable early and sudden increase of the electron density below 90 km. in the dark ionosphere following the great solar event of February 23, 1956; a similar flux has been suggested by D. K. Bailey[9], but his flux is assigned to a different origin. Both the transient increase of cosmic rays and the sudden increase of lower ionospheric ionization could occur within 10–30 min after the strong solar flare commenced, as was observed to be the case. When the fast electrons stop arriving, the Earth's potential would commence to rise, by admission of nuclei, until it and the cosmic-ray intensity return to their normal values. The arrival of the slow magnetic clouds, after the lapse of 1–3 days, could then give rise to other effects, including magnetic storms and temporary decreases of cosmic ray intensity.

The value 0·03 for β_s is consistent with the fact that current theories of stellar constitution are good approximations for the Sun and (presumably) for Blackett's average of five stars. For even if we adopt Chapman's model *A* with $\beta_s^2 = 9 \times 10^{-4}$ the forces of electrostatic repulsion are only about one-thousandth of the corresponding forces of gravitational attraction.

If a star possessed a charge such that β_s approached or exceeded the value 1 and this charge became located mainly near the surface of the star, the forces of electrostatic repulsion alone would make its outer parts unstable and so lead to their expulsion. This suggests one possible explanation of novæ and supernovæ. A necessary accompaniment of such an explosion of a rotating star is the ejection of magnetized clouds and relativistic electrons; this alone would explain the existence of the mysterious spectra of certain novæ and also the polarized light and strong radio noise emitted by the Crab Nebula.

The emission of strong radio noise from large regions around some galaxies, such as the Galactic Halo, may be explained by regarding each of these regions as the atmosphere of the negatively charged and rotationally magnetized galaxy concerned. For such an atmosphere would necessarily contain trapped electrons with relativistic energies.

Lastly, we may expect that when two such charged and magnetized galaxies enter into collision they would set up strong electromagnetic disturbances in each other's atmospheres and so generate the intense radio noise which has been observed in such collisions.

A discussion of possible sources of the stellar net charges, some possible difficulties which may be raised by my hypothesis and some possible tests of it will be given in Part 2.

2

Possible sources of the stellar charge $-Q_s$, certain criticisms which may be raised against these hypotheses and possible tests of them will now be discussed.

A possible source of $-Q_s$ is provided by one of the following alternative hypotheses H_1 and H_2.

H_1: The thermonuclear processes in the interior of a star like the Sun generate certain particles, provisionally named 'astrons', each possessing a small mass m_a and a positive electric charge e_a many times smaller than the electronic charge e and able to penetrate matter as easily as a neutrino can. Under this hypothesis the star acquires a negative charge $-Q_s$ which is ultimately limited by the flow of nuclei into the star and the flow of electrons out of it.

H_2: As suggested in an earlier publication[10], the four-dimensional space-time universe U_4 is a hyper-surface in a five-dimensional universe U_5 and the laws of conservation of energy, momentum and electric charge hold true exactly in U_5 and only approximately in U_4. Consequently, there can exist streams of electrically charged particles from U_5 into U_4 or vice versa. Also the geometrical character of this hypothesis requires that these streams depend on the local metric of U_4, that is, on the local physical conditions in U_4; thus the streams inside a star would be different from those outside it. The streams from or into U_5 could then give a net negative charge to the star; they could also maintain this charge constant under any possible drains due to the emission of electrons into space and the attraction of nuclei from space.

This hypothesis H_2 may appeal more to theoretical physicists, for it can also serve to unify the theories of the gravitational, electromagnetic and quantum fields and one theory of cosmology[10]. The present application of H_2 to the interior of a star suggests that a correct theory of nuclear forces would be one that could be unified with the other four theories in a five-dimensional mathematical form. This suggestion receives some support from Rayski's[11] recent publication entitled "A Six-dimensional Interpretation of Electrodynamics and Nuclear Interactions".

The first hypothesis H_1 is more easily linked with current views about the thermonuclear processes inside stars like the Sun. For this can be done simply by adopting two supplementary hypotheses, namely (h_1) that astrons are neutrinos and (h_2) that a proton carries the same charge e as a positron and an electron carries the charge $-e$. From these hypotheses and the two known nuclear processes:

$$n^0 \rightarrow p^+ + \beta^- + \bar{\nu} \text{ (antineutrino)}$$
$$p^+ \rightarrow n^0 + \beta^+ + \nu \text{ (neutrino)}$$

it can be deduced that a neutrino carries the small positive charge e_a, and a neutron and an antineutrino each carries the negative charge $-e_a$. These hypotheses and deductions are also consistent with the current assumption that the principal thermonuclear process in the Sun is the proton-proton chain reaction in which two β^+ particles and two neutrinos (ν) are released for every four protons involved. Moreover, they are consistent with the remarkable fact that the neutron behaves like a spinning negative charge.

By means of certain arguments based on current views about the flux of neutrinos out of the Sun, 5×10^{38} per sec., and the mean energy of each, 0·25 MeV., it may be inferred that a necessary condition for most of the neutrinos to escape from the charged Sun is that $e_a \ll 4 \times 10^{-16}e$. Also an argument suggested by Dr. M. J. Buckingham, based on the same value of the neutrino flux, 5×10^{38}, and on the age of the Sun, 5×10^{9} years, leads to the conclusion that $e_a > 4 \times 10^{-19}e$. It is remarkable that the net positive charge $e_h = 2 \times 10^{-18}e$ assumed by Lyttleton and Bondi[12] to be carried by a hydrogen atom lies between these limits to the value of e_a and is only five times as large as the lower (and nearer) limit. This fact and their use of the charge e_h to explain galactic recession suggest that some elaboration of my hypothesis of negative stellar charges could also serve to explain this recession. For example, the additional assumption that the Population II stars in the galaxy have charges Q_s such that $\beta_s > 1$ and are so related in number to the Population I stars that the average value of β_s for the galaxy is about 2·2 could allow the forces of mutual repulsion between my negatively charged galaxies to set up the same velocities of recession as those set up by the excess positive charge in the universe of Lyttleton and Bondi.

The hypothesis H_1 may possibly form part of the hypothesis H_2 when the latter has been developed mathematically and otherwise.

It may be argued that the main hypothesis is untenable because : (*a*) interstellar space appears to be too highly conducting and (*b*) the negatively charged star would quickly lose its charge by the emission of free electrons. This argument is nullified by the hypothesis H_2 under which there exist streams of charged particles from or into U_s which can replace any lost negative charge by an equal amount of fresh charge. But even under the hypothesis H_1 this argument has little force until, (*a*) it can take full account of the evidence that now exists that interstellar space contains coherent magnetic clouds of ionized hydrogen and that in the Solar system such clouds are continually flowing away from the Sun (see Parker[13]), and (*b*) it can be proved that a highly magnetized sphere of hot condensed hydrogen like the Sun cannot under any conceivable distribution of its negative charge $-Q_s$ retain for long the charge which is left by the emission of my positively charged neutrinos.

Another possible criticism is that my theory does not account for the existence of an extended spectrum of cosmic ray energies. This criticism is met by pointing out that not only do the attracted nuclei start from points at different distances from the Sun but also different nuclei encounter different obstacles on their way to the Earth's orbit, such as the magnetic clouds mentioned above, and so lose different amounts of energy through these encounters. The latter process would become more effective if, as is probable, most of these magnetic clouds were negatively charged by electrons trapped in their fields.

A fourth objection which may be raised against the theory is that during some six years the general magnetic field of the Sun was opposite to that set up by the negative charge $-Q_s$. This is met by Blackett's suggestion that a slow electromagnetic oscillation may be superimposed on the unidirectional general field and by the possibility that the observed effects of the latter may sometimes be obscured by those due to the irregular fields arising from turbulence.

Another possible criticism is that the theory is contradicted by the apparent transient generation of low-energy cosmic-ray particles in the Sun following certain flares. This criticism is met by referring to the discussion in Part 1, in which it is shown how the very fast solar stream of electrons, inferred from the radio observations of Wild *et al.* at times of strong solar flares, can transiently lower the electric potential of the Earth and so transiently increase the intensity of the flow of low-energy primary cosmic-ray particles into the Earth's atmosphere.

Lastly, it may be argued that the electric fields in the Sun's atmosphere set up by its charge should be revealed by the presence of large Stark effects in some of the spectral lines. This argument is not conclusive, because the Stark effects which have been observed are usually attributed to atomic electric fields which can be greater than the solar fields, and also because about 43 per cent of the lines in the spectrum of the Sun are as yet unidentified and may therefore arise in part from large Stark effects.

A more complete account of this work is in the course of publication in the *Journal and Proceedings of the Royal Society of New South Wales*. In that account three possible experiments are described, and two predictions are made which may serve to test the theory or parts of it.

One of these experiments is to determine, by means of satellite-borne magnetometers, the Earth's equatorial magnetic field and its direction at distances up to at least ten Earth radii. Another experiment is to determine whether Bostick's plasmoids (or rings) carry net negative charges by firing them into or through Faraday cages.

One of the predictions is that, during the next ten years, the value of the Sun's north polar magnetic field will return to the mean value and direction, -4 gauss, which were found by Hale and Langer.

I wish to acknowledge the valuable help which has been given to this work by the expert advice and criticisms of numerous colleagues and friends, in particular those of Profs. S. T. Butler, H. Messel and C. N. Watson-Munro, and Drs. M. J. Buckingham, R. G. Giovanelli, R. E. B. Makinson, H. D. Rathgeber and J. L. Pawsey, and Messrs. A. F. A. Harper, J. P. Wild and H. Wood.

Note added in proof. If the formula (1) is also applied to the planet Jupiter, which resembles the Sun in its chemical constitution and in emitting strong, elliptically polarized radio noise, the polar magnetic field resulting from a uniform distribution of Q_s and from the planet's rotation has an intensity of about 5 gauss. This approximates to the value 7 gauss derived by A. G. Smith and T. D. Carr (*Astrophys. J.*, 130, 641 (1959)) from observations of Jupiter's radio noise.

PADDY SOILS AND RICE PRODUCTION

By Dr. H. GREENE

Rothamsted Experimental Station, Harpenden, Herts

DURING 1954, an annotated bibliography[1] of rice soils and fertilizers was compiled by G. V. Jacks and M. Kathleen Milne. This has more than 900 entries, but does not include some valuable papers on paddy soils in Japan that were presented at the fourth session of the International Rice Commission, held in Tokyo during 1954. Much of the following summary is based on three of these papers: a historical review[2] by Harada *et al.*; a study of the chemistry of paddy soils[3] by Shioiri and Tanada; and a study of soils and fertilizer use[4] by Mitsui.

Paddy fields of Japan are mostly located on well-drained alluvial soils of Recent origin. Their subsoil remains continuously oxidized to a considerable depth: below this there may be a gley horizon due to a permanent water-table. Irrigation during the summer sets up reducing conditions in the topsoil which becomes bluish grey to a depth of 25 cm. or so. When the crop ripens the fields are allowed to dry and the whole furrow slice becomes oxidized. When irrigation is resumed in the spring vigorous growth of algae and duckweed occurs. These take up carbon dioxide during the day, allowing the surface water to become alkaline by the afternoon, and give off carbon dioxide at night so that the surface water is weakly acid by the early morning. Oxygen produced during the day and diffusing atmospheric oxygen reach the soil surface, which remains brown to a depth of a few millimetres. Below this a very thin (0·5 mm.) layer of hydrated ferric oxide may sometimes be found. This is an embryonic upper iron pan formed by oxidation of ferrous compounds diffusing upwards from the bluish grey reduced layer. The diffusion of iron seems to be accompanied by localized and perhaps progressive bleaching of the bluish grey layer. In this layer reduction of nitrate, sulphate and ferric ions takes place and a consequent lessening of acidity. A lower more substantial pan containing iron and manganese oxides may be formed by downward diffusion at the junction of the reduced layer and the oxidized subsoil. Similar iron pans have been observed in north-west England by Crompton[5]. If concentrated nitrogenous fertilizers are applied at the surface, nitrate formed in the surface layer is leached downwards; denitrification occurs in the reduced layer and is accompanied by loss of gaseous nitrogen or nitrous oxide, this loss being more serious than that due to deep percolation. The soil of an irrigated field can be represented as in Fig. 1.

Yields are increased by 10 per cent or more if paddy fields can be dried off between successive crops. When air-dried paddy soil is flooded, anaerobic micro-organisms regain the ascendancy and ammonium nitrogen is produced in greater amount than from continuously wet soil. The increase, amounting perhaps to 20 kgm. nitrogen per hectare, is readily taken up by the rice plant. Air-drying prior to flooding also increases the availability of phosphate. Aoki[6] concluded that the effective part of the phosphoric acid in paddy soils appears to be present as iron compounds, their solubility being increased by conditions of reduction. Similar conclusions are drawn by Paul and De Long[7], Islam and Elahi[8] and by Gasser and Bloomfield[9], who found that phosphate associated with iron is mobilized by anaerobically fermenting organic material. Ponnamperuna *et al.*[10] consider that the rice plant benefits from the increased availability of iron but may suffer from an excess of reduced substances.

Ammonium sulphate should be worked into the soil before the first flooding or, surprisingly, it can be mixed with peat or peaty soil to form egg-size balls which can be thrust into the flooded soil. This latter method is specially recommended for 'degraded' paddy soils in which damage from hydrogen sulphide is feared. It has recently been stated[11] that urea is preferred to ammonium sulphate as nitrogenous fertilizer for 'degraded' paddy soils as well as for acid soils of Japan. In lowland paddy soil the sulphate of chemical fertilizers is readily reduced to sulphide which, if soluble, inhibits respiration of plant roots and so prevents selective uptake of potassium and uptake of phosphate and other plant nutrients. This physiological disorder involving root-rot is known in Japan as *akiochi* or 'fall-down'. According to the observations of Sethi[12], Crafts and Broyer[13], van Raalte[14], Vlamis and Davis[15], rice thrives in waterlogged soil because its young roots supply oxygen to the otherwise reduced soil: if iron is present in solution, the young roots acquire a yellowish brown coating of ferric hydroxide gel which apparently protects the roots against moderate amounts of hydrogen sulphide. The oxidative action of the roots ceases or grows less at flowering, this decline possibly being associated with differential response to potash of young and older rice plants noted by de Geus[16].

The 'degraded' soils which occupy about 17 per cent of the lowland rice area of Japan are described as follows: (1) the furrow slice is grey and shows little evidence of 'active' iron (as estimated by Truog's method using sodium sulphide and oxalic acid); (2) the plough sole layer is usually bleached; (3) below the plough sole there is a layer where ferric and occasionally manganic oxides accumulate; (4) in mid-summer the furrow slice emits hydrogen sulphide

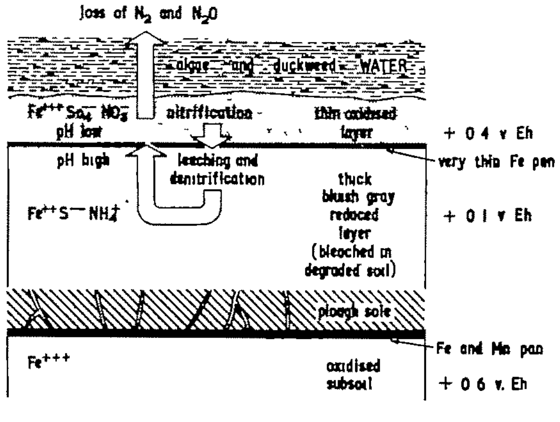

Fig. 1

gas ; (5) roots of rice are whitish and lack the coating of ferric oxides which would protect them from damage by hydrogen sulphide. This description corresponds closely to that given by Koenigs[17] for a 'sawah' profile in Java : de Gee[18] has determined the oxidation potential of the 'sawah' profile. His results are shown in Fig. 1. According to Mitsui[4], the 'degraded' paddy soil occurs on siliceous materials such as are derived from acid igneous rocks or sandstone. It may be supposed that these materials occur mainly as low-lying alluvial deposits, that they contained little iron at the time of deposition and were readily leached.

Observations of Bloomfield[19,20] suggest that leaching and precipitation of iron oxide in poorly drained soils commonly involve formation of soluble complexes of ferrous iron by the action of decomposing plant remains. The complexes are sufficiently stable to be transported by percolating water, but if brought into contact with ferric oxide they are sorbed and the ferrous iron is readily re-oxidized. Following up these ideas, Jeffery[21] has added excess water to oxidized soil plus organic matter and has observed : (*A*) a rapid fall in redox potential, which is followed by (*B*) a fairly rapid recovery ; and by (*C*) a slow decline such as is given by soil plus water in the absence of added organic matter. He ascribes stage *B* to oxidation by ferric oxide originally present in the soil. This recovery leads to a desirable situation *C* in which both ferric and ferrous ions are present. For stage *C* Jeffery derives an equation relating *Eh* and *p*H. The observations lead to a more precise understanding of the balance of oxidation-reduction at different seasons and at different parts of the soil profile. In a second paper[22], Jeffery develops an equation in an attempt to define optimum conditions for rice growth and thus the suitability of any given soil for paddy. Shioiri and Tanada[3] found in a laboratory test a marked fall in redox potential on adding excess water to samples from the furrow slice of paddy soil, whereas samples of upland soil showed little change. Paddy soil that had been treated with organic fertilizer produced abundant hydrogen sulphide when water-logged, whereas corresponding upland soil did not. The upland soil presumably had a greater reserve of ferric oxide. Accordingly, heavy applications of upland soil are used with some success to improve degraded paddy soils.

These studies, arising from the pioneering work of Prof. W. H. Pearsall (see review of Grist's book on p. 507 of this issue), are of more than academic interest : they should contribute to increased production of this crop, which is vitally important to so many millions of patient, hard-working people. Much is already being done. In Japan, soil survey (Endo[2]) has been directed to mapping different kinds of low-yielding land, including *akiochi* (degraded) paddy fields, acid soil, low-yielding volcanic soil, saline soil, poorly drained soil. Improvement is then sought by appropriate means, for example, by adding iron-rich materials to degraded soils and by appropriate use of fertilizers as described above ; by addition of calcareous materials to acid soils ; by improvement of drainage. D. H. Grist[23] rightly considers that improved water control is the best way of raising rice yields. The following may be included among the encouraging results obtained by use of fertilizers. Richardson[24], describing 81 field experiments on paddy fields in China, recorded the following responses to 60 kgm. per hectare applications reckoned as nitrogen, phosphate and potash : mean yield, 2,805 kgm. per hectare ; responses—nitrogen, +620 ; phosphate, +290 ; potash, +40 kgm. per hectare rough rice, that is, threshed grain. On the advice of Stewart[25], very numerous experiments with fertilizers have been carried out on farmers' fields in India. Yates, Finney and Panse[26] recorded, for 2,445 experiments in Bihar, India, a profitable response of 280 lb. threshed grain/acre to 20 lb. nitrogen per acre ; phosphate was profitable only on responsive soils. Numerous additional experiments during the period 1953–56 indicate[27] that a dressing of 20 lb. nitrogen/acre plus 20 lb. phosphate per acre would generally be the most profitable for paddy in India. In the north and north-east, the dressing of nitrogen can be increased to 40 lb. with or without application of phosphate ; in certain areas distant from the coast, the dressing of phosphate can be raised to 30 or 35 lb. phosphate per acre. Potash at 20 lb./acre gave a profitable return in some areas, including two centres in Bihar. Ashby[28] found from 173 completed experiments on farmers' wet paddy fields in Kelantan, Federation of Malaya, an economic response to 200 lb./acre of placed fertilizer supplying nitrogen, 23·5 ; phosphate, 20 ; potash, 25 lb./acre. In Zanzibar, Tidbury[29] found the most profitable dressing to be 2 cwt./acre ammonium sulphate plus 3 cwt./acre of superphosphate. It is worth mentioning these results that derive only in part from a more accurate appreciation of wet soils. The possibilities are more encouraging than might appear from the earlier investigations. Important observations on response to phosphate applied to wet paddy fields of British Guiana were made by Gasser[30]. Factorial experiments carried out on three kinds of soil gave results as shown in Table 1, while analysis of straw and threshed grain from these experiments gave percentage contents of phosphate shown in Table 2.

Table 1

Site	Soil	Threshed grain (lb./acre) With phosphate	Threshed grain (lb./acre) Without phosphate
Cane Grove	toxic aluminium	2,977	409
Mahaicony Abary	pegassy clay	2,740	1.769
Botanic Gardens	fertile frontland clay	4,126	4,102

Table 2

Site	Straw		Threshed grain	
	With phosphate	Without phosphate	With phosphate	Without phosphate
Cane Grove	0·036	0·036	0·159	0·117
Mahaicony Abary	0·049	0·038	0·244	0·160
Botanic Gardens	0·107	0·105	0·298	0·299

In comparison with the other low-lying soils, the higher fertility of the frontland clay (derived from marine alluvium) in the Botanic Gardens, British Guiana, is clearly shown in the satisfactory phosphate content of grain from plants which had not received phosphatic fertilizer. The soils increase in acidity and in content of exchangeable aluminium in the order : Botanic Gardens < Mahaicony Abary ≪ Cane Grove. The Cane Grove soil, considered to be formed by sedimentation in brackish water, is like the gyttja soils studied by Wiklander and co-workers[31–33] in Sweden, and is related also to soils of mangrove swamps studied by Tomlinson[34,35] and by Hart[36] in Sierra Leone and to the 'gelam' soils of Malaya (Coulter, ref. 37). Such soils occur widely and I have suggested[38] that sulphur, readily leached from humid uplands in the form of sulphate, may be arrested in reduced form in lowland deposits together with elements forming insoluble sulphides. When air gains access to such deposits (for example, when water-levels fall because rain has been less heavy than usual) oxidation rapidly occurs, with formation of sulphuric acid in sufficiently high concentration to react with clay to form aluminium sulphate.

Of course, much has yet to be learned about these poorly drained or water-logged soils, which differ so sharply from upland soils that ordinary methods of analysis may be misleading or fail to yield significant results. At present it seems permissible to distinguish, as three corners of a triangular diagram, well-drained paddy soils, which are fertile; *akiochi* or degraded paddy soils which are infertile for lack of iron; paddy soils related to gyttja which are infertile owing to excess of aluminium. The preceding brief account refers to mainly mineral soils: some corresponding features are shown by peaty soils, for example, the pegassy soils of British Guiana seem related to gyttja. This subject will be more conveniently discussed on some later occasion. Current work (Bloomfield, C., private communication) indicates that decomposing plant remains mobilize not only iron but also many other elements of importance in plant nutrition.

THE CENTO INSTITUTE OF NUCLEAR SCIENCE IN TEHRAN

By H. A. C. McKAY
Director

TO meet the great world-wide interest in nuclear science and its applications, it has often been suggested that regional centres should be created. Each centre would provide training and research facilities for a group of neighbouring countries. The first of such centres to be established is the CENTO (Central Treaty Organization) Institute of Nuclear Science, formerly the Baghdad Pact Nuclear Centre, which now serves the three countries of the CENTO region, Iran, Pakistan and Turkey. The Institute is concerned exclusively with the peaceful uses of nuclear science, and forms one of the quite extensive economic activities of the Central Treaty Organization.

The original Nuclear Centre in Baghdad was formally opened on March 31, 1957 (see *Nature*, 179, 936; 1957) and trained about sixty Middle East scientists in nuclear techniques, before the Iraqi revolution brought operations to a close. A decision to re-establish the Centre in Tehran was taken jointly by the CENTO countries in January 1959, and on June 23, 1959, H.I.M. the Shahenshah of Iran performed the opening ceremony in the presence of a distinguished audience. Two training courses have since been held in Tehran. The re-naming of the Baghdad Pact necessitated the re-naming of the Centre, and the present name was adopted in November 1959.

All the CENTO countries contribute to the running of the Institute. Its scientific policy is in the hands of a Scientific Council consisting of a leading scientist from each of the four countries; the United States sends an observer. The Scientific Council reports to the Economic Committee of CENTO, and in general administrative matters the Director of the Institute maintains liaison with the Deputy Secretary General for Economic Affairs of CENTO. The British representative on the Scientific Council is Sir John Cockcroft, and the Institute owes him a great debt for his continued efforts on its behalf.

Finance and staff are provided by all the CENTO countries. Iran has provided accommodation in the new and modern Faculty of Science building in the University of Tehran. The United Kingdom has provided the initial stock of equipment, worth about £20,000, most of which was flown out by charter plane.

The link between the Institute and scientific establishments in the United Kingdom is vital to its operation. Much of the value of the Institute is due to its serving as a channel for British knowledge and experience in the nuclear field to reach the CENTO region. The United Kingdom Atomic Energy Authority has provided the Director and five other scientists out of the Institute's total complement of twelve scientific staff. The British staff have been carefully chosen so that between them they cover the basic fields of nuclear physics, electronics, radiochemistry and health physics; the number could not be cut without affecting vital services. The present Director is a radiochemist from the Atomic Energy Research Establishment at Harwell, and his predecessor, W. J. Whitehouse, was a nuclear physicist from the same Establishment. The personal connexions with Harwell are such that advice and help are readily obtained from that source.

While the British staff cover the fundamental physical and chemical aspects of nuclear science, staff from the region are often specialists in one or other of the biological sciences. They are thus able to co-operate with the British staff in the development of applications of interest to the region, especially in agriculture. Attached to the Institute there is also a CENTO Senior Research Fellow, Dr. C. J. Banks, an entomologist from Rothamsted Experimental Station, who is applying radioisotopes in his particular field. The region staff have in many cases had a period of training in the United Kingdom before joining the Institute.

At present the Institute is engaged primarily in work with radioisotopes, which offers the best starting-point for the region in nuclear science. Its main activities fall under two heads: training courses and research projects.

The first training course in Tehran lasted nearly two months, from mid-September to mid-November 1959. It was attended by thirteen students from Iran, Pakistan and Turkey, all having at least a university science degree, and two being professors at their own institutions. (The Institute actually has space and equipment for twenty students working in pairs.) The course was comparable with those given at Harwell, Oak Ridge in the United States and elsewhere, though perhaps rather fuller, and taking rather less for granted as regards familiarity with modern laboratory techniques.

Ten of the students are staying on at the Institute for the rest of the academic year for advanced training or research, largely in fields of their own or their home institution's choosing. It is something of an experiment to operate in this way. A criticism of the courses given earlier in Baghdad was that they were too short; in the time available, the students could not digest their new knowledge sufficiently to be able to use it immediately on their return home. (The same criticism would apply, perhaps even more strongly, to most radioisotope courses elsewhere.) Merely to extend the courses did not seem very satisfactory, because the essential ground was already covered. However, by keeping the students on project work for several months, it is hoped to provide a sufficient assimilation period in the right atmosphere. It is hoped, too, that the students will catch something of the research spirit from the experienced scientists at the Institute.

The projects now in progress include water-flow studies by radioactive labelling and tritium counting; testing of cement and of archæological specimens by beta-ray back-scattering; solvent extraction and ion exchange work in solution chemistry; synthesis of labelled carbon-14 compounds; observation of cytological changes in plants grown under the influence of phosphate labelled with phosphorus-32; and a study of the food reserves of certain insects. There is also quite a large project on the study of the migration of wheat pests (*Aelia* and *Eurygaster* species) by radioactive labelling of the insects. This was initiated by W. T. Spragg, chief chemist, at the Centre in Baghdad, and pilot-scale field-trials were carried out last spring in Anatolia and near Tehran, under CENTO auspices. A further trial is planned this year.

When the students return to their home establishments, the Institute intends to continue to follow the progress of their researches, and to send its staff on consultative visits. Being in the region, it can offer much closer support than could a training centre in Europe or the United States.

The second course at the Institute in Tehran was a special radioisotope course for agriculturists, running from mid-January to mid-March. Eleven students from the region attended, of the same general calibre as those on the first course. The course contained less nuclear physics and radiochemistry than the first (general) course, and concluded with a series of lectures and experiments dealing specifically with biological topics.

Although the main emphasis at the Institute is on radioisotope work, with some bias towards agricultural applications, it is prepared to help in any field of nuclear science, in accordance with the needs of the CENTO region countries. The staff, between them, are of quite wide experience, and can moreover draw on the very large resources of Harwell. Assistance has already been given in testing uranium- and thorium-prospecting equipment, and some of the students are receiving preliminary training for reactor and gamma-irradiation work. Moreover, the Institute has been promised facilities on the 5-MW. swimming-pool reactor, on which construction work is just starting at the University of Tehran Nuclear Centre a few miles from the Institute. The University of Tehran also possesses a 3·5-MeV. Van de Graaff machine, a mass spectrometer, and a beta-ray spectrometer, which it is proposed to erect at its Nuclear Centre.

In the medical field, the Institute is giving all the encouragement it can to the establishment of a radioisotope clinic in Tehran. Until this exists, medical students at the Institute can get very little direct practical experience in their own particular field, although they can still obtain a great deal of benefit from the instruction given in general nuclear techniques. Most of the equipment necessary for such a clinic is already in Tehran, and there are medical men keen to use it, so it is to be hoped that work will start in the fairly near future. It may also be noted that the United Kingdom has recently presented a 1,000-curie radiocæsium therapy unit to the Faculty of Medicine of the University of Shiraz.

Certain lessons have been learned in setting up and operating the Institute, which may be of interest to those planning a similar venture. As regards equipment, it is important for the Institute to be well stocked with instruments of general use, such as ovens, thermostats, *p*H meters and incubators; it is usually too late to think of ordering such items for specific researches after the students arrive. A quick supply channel for chemicals, radioisotopes and other small items is vital, and Tehran's position on trunk air routes was a factor in the choice of location. Rapid clearance of radioisotopes through the Customs has been arranged with the Iranian authorities. The Institute has found it necessary to instal its own electrical generator to ensure a constant supply, and steps are being taken in co-operation with the University of Tehran to put into operation a liquid-nitrogen plant.

As regards staff, the CENTO region countries have understandable difficulties in releasing good scientists to work at the Institute. Partly this is because trained scientists are in great demand in their home countries, and partly because of financial difficulties; the latter will, it is hoped, be surmounted. Technicians and junior laboratory staff are also hard to find, and there is a great need to train people for such jobs, as well as to overcome the social attitudes that tend to deflect people from them. The Institute offers training especially in electronics under D. R. Cockbaine, chief electronics engineer, and it is to be hoped that the CENTO countries will take full advantage of the opportunity; electronics servicing is an essential part of a nuclear science programme.

On the financial and administrative side, the Institute has a fair degree of autonomy within the broad lines of policy laid down for it. The finances are largely centralized in a single budget, from which all expenses are paid according to the Institute's own rules (which are based on those of the CENTO Secretariat); this avoids the complications of having to deal with the separate regulations of four different Governments.

Certain aspects of the Institute's work presuppose co-operation with a national atomic energy authority. Any operation involving possible release of radioactivity outside the Institute itself may come in this category. The Institute's insect-labelling project is the most important immediate example, and waste disposal is another which will arise in the future (for the present all radioactive waste is stored). Relations have therefore been established with the Atomic Energy Commissions of the three countries of the region.

The immediate success of the Institute encourages the hope that it will become established as a scientific centre of high reputation in the Middle East. Its character may change somewhat, as the atomic energy programmes of Iran, Pakistan and Turkey get under way, and they begin to conduct their own radioisotope courses. (For Iran and Turkey especially, these will have the advantage of being in their own languages.) The future trend at the Institute may then be towards more specialized training and towards research projects. The benefits should be felt in many fields, owing to the wide ramifications of nuclear science.

OBITUARIES

Prof. E. P. Stebbing

Prof. E. P. Stebbing, whose death at the age of ninety occurred on March 21, must have surpassed the now almost legendary Sir William Schlich, whose pupil he was, both in the number of years he presided over a forestry school, and in the number of forestry students who passed through his hands. His influence on forestry was far greater in the educational field than in any other, despite his special interest and numerous writings on forest entomology and soil erosion.

Interest in entomology showed early when he was still under training for the Indian Forest Service at the Royal Indian Engineering College at Coopers Hill. In 1900 he had the distinction of being the first forest officer in India to be appointed to a scientific research post, that of forest entomologist, having served in an executive capacity as assistant and deputy conservator during his first seven years. The post of forest entomologist had only been sanctioned for two years, and was not renewed; but it so happened that the post of superintendent of the Indian Museum at Calcutta was vacant, and Stebbing was given an officiating appointment. When the Forest Research Institute was established at Dehra Dun in 1906 he was the obvious man to deal with entomology, and he worked there as Imperial forest zoologist until his return to Britain in 1910.

During his time in India and Burma he did a remarkable amount of pioneer work, the results being published as *Forest Bulletins* (8) and *Leaflets* (5), and *Indian Forest Records* (3) and *Memoirs* (5), dealing with insects injurious to many of the chief timber species, namely, teak, *Shorea robusta*, *Acacia arabica* and the conifers, as well as with the lac insect. His best-known entomological work is his "Indian Forest Insects of Economic Importance: Coleoptera" (1914). Stebbing's biological work was of a higher standard than his contributions to taxonomy, which obviously did not interest him so much; but in those days he could scarcely have avoided it since so few of the insects with which he was concerned had been named and described.

In 1910 he was appointed lecturer in forestry in the University of Edinburgh, and nine years later became the first professor of forestry there. He had thus completed more than forty years when he retired in 1951 (*Nature*, 167, 670; 1951).

Stebbing travelled widely, having visited Macedonia (as transport officer during the First World War) and the U.S.S.R., and afterwards many of the British and French Colonies, especially in West Africa. The country of his choice was patently France, and annually from 1921 he took groups of students there for part of their training. He had many friends in the Département des Eaux et Forêts, and just before he retired he was doubly honoured by having the Croix de Chevalier de la Légion d'Honneur conferred on him, and one of the famous ancient oaks in the Forêt de Tronçais named after him.

On the topic of erosion, Stebbing was strongly of the opinion that the administrators were inexcusably slow in taking—or enforcing when necessary—soil conservation measures, by preventing further denudation of vegetation, restricting excessive grazing, and undertaking constructive works. From his writing and speeches on this subject, he might have been considered somewhat of an alarmist, especially as to the rate of the 'advance of the desert' everywhere, though with special reference to the Sahara.

His most enduring publication will undoubtedly be his historical book on the "Forests of India" (1926). It is truly monumental in size, approaching 1,900 pages in three volumes covering the subject in great detail from its beginnings in the 1850's down to 1925. For the third volume covering the period 1900–25, he was able to use freely memoranda prepared for him by a large number of serving officers, but in doing so he drew on his own experience and added his personal views, thereby making the story much more alive and interesting than it would otherwise have been. He re-visited India and Burma in connexion with this work and was engaged on the preparation of a further volume to bring the history up to 1940 at the time of his death—I recently took over from him the task of completing and publishing it (extending it to the end of the British regime in 1947).

As a teacher, Stebbing had very definite ideas of what was best for his students, and kept as firm a rein on the curriculum as he did on his horse. He always rejected any suggestion of loading up his undergraduate course with more basic science, considering that practical forestry had not yet advanced enough for it to be of any value: his course was accordingly more weighted on the technological side than elsewhere—which might not have been expected in view of his own early specialization. Possibly he was inclined to overstress the model of advanced European practice, rather curiously adding an overdose of engineering and surveying appropriate to India and Burma in the old days.

No account of Stebbing's life would be complete without reference to his personality. Small and spare, he was exceptionally 'tough' both on foot and as a horseman, and remained so until an unusually advanced age. Stories of his walking performances still persist in India, while his equestrian ride from his home in Kent (Romden Castle) to London in 1935 when he was sixty-five was no isolated feat.

During much of his time at Edinburgh, Stebbing had the largest number of students among the four university schools of forestry in the United Kingdom. Many of them had been sent from overseas, and these and many others are serving or have served in the forest services of Britain and all countries of the Commonwealth; in fact, cases could be quoted where the large majority of the officers of the Forest Department were his men. One can safely prophesy that his record will never be repeated, and he will long be remembered in all forestry circles.

H. G. CHAMPION

Prof. E. J. Kraus

DR. EZRA JACOB KRAUS died at Corvallis, Oregon, on February 28 at the age of seventy-four. He was distinguished throughout the United States both for his massive contribution to scientific horticulture and for his flair for friendship with young botanists. He graduated from Michigan State University in 1907 and spent the first eleven years of his academic career in Oregon State College. In 1919 he went from Oregon to the University of Wisconsin; after a few years there he accepted an invitation to a chair in the botany department in the University of Chicago, where he stayed until his retirement in 1949.

The scientific work for which Kraus is remembered is his analysis of the balance of carbohydrate and nitrogen in plants in relation to fruiting. He demonstrated that many crop plants did not bear fruit unless a balance was maintained between these two classes of compounds. Some of his disciples greatly over-simplified his ideas by talking loosely about a carbohydrate–nitrogen ratio (or even a C/N ratio); but Kraus himself always realized that the relation between chemical composition and fruiting was a subtle and complex one, and he was impatient of these facile simplifications. Kraus's ability to diagnose why crops failed to bear fruit was quite astonishing. He showed (for example) how low yields in the apple orchards in the Hood River valley were due to over-manuring coupled with early pruning. A score of other examples could be cited, where fruit growers were able to improve their yields by controlling the balance of carbohydrate and nitrogen by means of simple horticultural practices: manuring, pruning, ringing and the like.

In Chicago he turned his attention to the anatomical effects of plant growth hormones, and (during the War, when he was attached to the U.S. Department of Agriculture) to the use of hormone-like chemicals for weed control; in both these fields he did important work.

But in the memories of hundreds of students Kraus will survive as a man rather than as a research worker. His influence on the graduate students who passed through his hands was enormous. It was conveyed through a quiet approach, a slightly cynical modesty, a bubbling sense of humour, and above all an impression that the priority which Kraus put first in his life was to spend time with young men, to talk to them, to travel with them, to pass on to them his enthusiasm for scientific horticulture. He was a capital 'debunker': indeed his interest in applied science and his suspicion of pure science sometimes led him to distrust research which seemed too sophisticated, and the succession of young men who had the privilege of his friendship remember with zest his mocking pragmatism.

Kraus disliked administration and committees, and he retired early (partly on account of illness) to spend the rest of his life doing the work he loved in the place he loved. From 1949 until his death, as a visiting professor of horticulture at Oregon State College, he devoted his time to horticulture, especially to the production of new varieties of chrysanthemums, and to cultivating his friends. He died after a long and painful succession of illnesses.

Kraus received wide recognition for his distinction in American botany. He was president of the Botanical Society of America in 1933 and of the American Society of Plant Physiologists in 1928, and he won many medals and prizes for his horticultural work. Much of his work is inevitably out of date: but his influence on a generation of botanists will endure.

E. ASHBY

Sir Leonard Woolley

CHARLES LEONARD WOOLLEY, who died on February 20, nearly eighty years old, was perhaps the most internationally famous archæologist of his generation. This reputation was built upon far more than the fact that he best represented the ordinary man's notion of an archæologist, namely, a digger-up of the lore, but especially the treasures, of antiquity. Certainly this was his life's work, and certainly his successes in it were outstanding. He was constantly in the field (in Egypt, Syria, above all in Iraq), he never belonged to any institution, he never undertook to teach students (except by practical example to his assistants), and he scarcely attempted academic literature in his subject.

Yet even among those few who could have worked so widely and so hard as he, many would have fallen short for want of certain talents which Woolley possessed. First, by some scarcely explicable gift, he could find the most rewarding spot to work, whether it was the choice of Atshanah (the ancient

Alalakh) in 1937 among the multitude of settlement-mounds in its area, or the divining, season after season, at Ur of the most significant quarter to unearth in the great city. There he conducted, beginning from 1926, his most famous operation, revealing the royal tombs of Sumerian rulers who had held sway over the city in a period of unequalled splendour, about 2,500 B.C. as now believed, unhappily just before writing, already in use, had learned to record history.

In this great discovery also was best exercised the next in order of Woolley's talents, namely, a fine appreciation of materials in the ground, how they should each be reached, traced, or penetrated, how objects sighted should be protected from impacts of tools or of the atmosphere, how they should be lifted, and how first-aid should be given for their protection, transport, and even their ultimate reconditioning. Many almost deceptively 'well-preserved' exhibits in museums are now substantially as they left Woolley's hands, not restored or falsified, but skilfully extricated by him and remoulded to the shapes which they had lost by decay and pressure of earth. Much of his work of this kind was brilliantly improvised in days which, although not long past, were before the very recent development of preservation laboratories and techniques in museums.

Woolley had, moreover, a notable facility of exposition, which worked in two ways: an attractive lecturer and writer for general audiences, he was also —more important for one whose discoveries could well speak for themselves—a judicious author of excavation reports, that difficult marginal literature which, always bulky, is worthless if it strives for effect, repulsive and unreadable if too painfully 'scientific'. Woolley's many publications were highly successful in these two kinds; his popular works are both interesting and well founded upon his discoveries (whereas his few attempts at more general themes are not very valuable), and his large volumes of excavation reports have the virtues of well-arranged matter, ample pictures and plans, and careful description based upon his industrious recording in the field. Such descriptive parts can nearly always be read with interest and ready understanding. Some have, indeed, criticized his observation as not being of the exactitude demanded by the most recent methods, and it is true that Woolley could be intuitive in his perception of archæological levels and his mental reconstructions of buildings and fragments. But such criticisms seem not to make enough allowance for the character of most Near Eastern sites, and the pell-mell of dwellings and artefacts of different ages, often jumbled together, which they usually exhibit.

Woolley's lively mind and exploring intelligence, if they sometimes led him beyond his evidence, were of more service in suggesting many true and fruitful consequences of his discoveries. These, as great and varied as have fallen to any modern digger, are his principal bequest and his enduring memorial.

C. J. GADD

Dr. Eric Boehm

DR. ERIC BOEHM, who died suddenly at Cardiff on December 28, was a well-known and respected figure in industrial chemical and pharmaceutical circles. Born in Breslau, Silesia, sixty-one years ago, he served a pharmaceutical apprenticeship in the town of Schreiberhau and later studied at the University of Berlin, graduating in 1922. He followed this with postgraduate training which, in 1925, resulted in the award of a Ph.D. He later studied bacteriology at the Robert Koch Institute in Berlin. The pre-war political situation in Berlin forced him and his family to leave Germany for Great Britain.

As a research worker he had become associated with Prof. Sabaletschka after the latter had introduced the now well-known esters of *p*-hydroxy-benzoic acid. Their association resulted in establishing these compounds under the trade names of 'Nipa Esters' as extremely useful, reliable and non-toxic preservatives for pharmaceutical and medicinal products and for foodstuffs. In 1938 these two workers showed that esters of gallic acid showed very promising anti-oxidant activities; this led to the widespread use of propyl gallate as an anti-oxidant for animal fats to prevent or retard rancidity. Its proved non-toxicity was recognized in 1948 when the United States officially approved its incorporation in fats for human consumption, to be followed by similar recognition in Britain and elsewhere.

In 1942, Boehm showed that certain mono-aryl and mono-alkyl ethers of ethylene glycol possess bactericidal activity. Interest centred chiefly around the phenyl ether of ethylene glycol ('Phenoxetol'), which was investigated bacteriologically and clinically by Berry, Gough *et al.* It showed unusual activity against *Ps. pyocyanea* and during the War, in the early days of penicillin, when topical application to wounds was, of necessity, used, a combination of 'Phenoxetol' with penicillin widened the antibacterial spectrum of the latter and also prevented its decomposition in the wound.

Dr. Boehm was that rare combination of an able scientist and capable business administrator. He also combined rare intellectual qualities with integrity, charm and kindness, as those who had the privilege of knowing him can testify.

H. BERRY

Prof. H. Stansfield

PROF. HERBERT STANSFIELD, whose death occurred on March 14, was appointed to the chair of physics and electrical engineering at University College, Southampton, in 1912. Previously he was a lecturer in physics in the Victoria University, Manchester. In 1919 he was transferred, with other Departments of the College, from the old Hartley Building to the new site at Highfield.

Research undertaken at Southampton by various members of his staff, under his direction, was started in the late 'twenties. His main interest was in optics, particularly with modifications to the Michelson interferometer experiments on the velocity of light. One summer he co-operated with the Royal Navy on sound recordings of gunfire. Setting up his apparatus in an area where no reports were expected, many yards of photographic paper recordings from an Eindhoven string galvanometer were processed and examined, and the nil report confirmed.

Past students will remember Prof. Stansfield's very characteristic action in stroking his fountain pen on his beard in order to charge some piece of electrostatic equipment in lecture demonstrations. Another characteristic was his exceptionally dry skin. He would touch 200-V. terminals with his fingers and then to be quite sure he would moisten them and repeat the action and remark, "Yes, I am sure they are alive"!

He retired in 1932 at the age of sixty, and the opportunity was then taken to separate the Department of Electrical Engineering at Southampton from Physics, and join it with the Departments of Civil and also Mechanical Engineering in the Engineering Faculty. C. E. CHESTER

Mr. W. H. Searle, B.E.M.

WILLIAM SEARLE, who was for sixty-three years fisherman collector on the staff of the Marine Biological Association of the United Kingdom, died at Plymouth on April 6, at the age of eighty-four. 'Bill', as he was affectionately known by all, must live in the memory of a great number of biologists, from all over the world, who visited the Plymouth laboratory either as research workers or students. It can be truly said that he played a very important part in the development of marine biology through his remarkable knowledge of the fauna and flora and its local distribution as far afield as Salcombe. He was able to produce almost any organism when required, though their specific names were not easy to interpret when marked by a broad Devonshire accent. Searle joined the Association's staff in December 1895, and worked tirelessly and devotedly, for many years single-handed, in small vessels which have become part of the history of marine biology, *Anton Dohrn*, *Busy Bee*, *Huxley*, *Oithona* and finally *Gammarus*, now in her thirty-seventh year.

He was elected an associate member of the Marine Biological Association in 1953. He also received the Queen's Coronation Medal; and in 1957 his services to science were recognized by the award of the British Empire Medal, of which he was very proud. He retired from service in 1958. F. S. RUSSELL

NEWS and VIEWS

New Director of the Science Museum, London: Dr. D. H. Follett

ON taking up his duties as director of the Science Museum in succession to Dr. T. C. S. Morrison-Scott (see *Nature*, March 26, p. 888), Dr. D. H. Follett will relinquish his post as keeper of the Department of Electrical Engineering and Communications in the Museum, to which he was appointed in 1957. Dr. Follett graduated from Brasenose College, Oxford, in 1929, in the honours school of physics. He then entered the firm of Adam Hilger, Ltd., where he was engaged in developing the application of photoelectric methods, particularly to spectrophotometry. At the same time he carried on part-time research in cosmic rays at Birkbeck College under Prof. P. M. S. Blackett, for which he was awarded the internal degree of Ph.D. of the University of London. He joined the Science Museum staff in 1937 as assistant keeper in the Department of Physics, in which Department he remained, apart from the war years, until 1957, his special responsibility being for electricity and acoustics. During the War he served with the Meteorological Branch of the R.A.F. Volunteer Reserve and was engaged, among various duties, on the operational development of the cathode-ray direction-finding system for locating thunderstorms. He was appointed secretary of the Science Museum Advisory Council on its reconstruction in 1951, a post which he held for six years in addition to his other museum duties. During this period he acquired a broad view of the Museum's functioning in all its aspects. Apart from his special interest in museums and the history of science—he is a Fellow of the Museums Association and a member of the British Society for the History of Science—Dr. Follett has wide interests in science generally and physics in particular. He is a Fellow of the Institute of Physics, being vice-chairman of the Education Group, a Fellow of the Physical Society and a member of the Committee of Visitors of the Royal Institution.

Research at the Ministry of Aviation: Mr. E. B. Carter

MR. E. B. CARTER, at present serving as an assistant director in the Engine Research and Development Division of the Ministry of Aviation, has been promoted to deputy chief scientific officer and appointed director of engine production. He has a wide and varied experience of research and development on all types of aero-engine, ranging from piston engines through gas turbines to ramjets and rocket engines, which will be a considerable asset to him in his new job, in an engineering sphere where development and production are very closely linked together. Mr. Carter was born in 1912 in Halifax and received his early technical training at Halifax Technical College. On completion of the mechanical engineering course, he studied machine tool practice and was appointed assistant workshop instructor. In 1936, he became workshop superintendent and lecturer at Constantine College, Middlesbrough. Mr. Carter entered the Civil Service in 1939 on his appointment as a technical assistant in the Directorate of Engine Research and Development of the Air Ministry. From that time until 1955, his London Headquarters' service in the Air Ministry, Ministry of Aircraft Production, and Ministry of Supply alternated with periods of service as resident technical officer at the Bristol, Napier and de Havilland engine companies. In 1955, Mr. Carter was appointed assistant director in charge of research and development of ramjet and liquid-propellant rocket engines for aircraft and missiles, the post he relinquishes to take up his appointment as director of engine production.

Mr. J. D. Clare

MR. J. D. CLARE has been promoted to deputy chief scientific officer and appointed director of guided weapons research and development (Air) at the Ministry of Aviation Headquarters. In his new post he will be responsible for the development of the surface-to-air and air-to-air guided weapons for the Royal Air Force and the Army. Mr. Clare graduated at the University of Birmingham in 1940. He joined the General Electric Co., Coventry, as a student apprentice and later worked in the telecommunications laboratory on many aspects of carrier telephony systems. During this time he obtained his M.Sc. In 1945 he joined Sobell Industries as head of the radio laboratory and later became assistant chief engineer responsible for both the design and development for production of commercial radio and television receivers. In 1950 he joined the Ministry of Supply at the Radar Research and Development Establishment, Malvern, and worked on high-power precision tracking radars. On the amalgamation of the Radar Research and Development Establishment with the Telecommunications Research Establishment to form the Royal Radar Establishment, he joined the Guided Weapon Department and in 1955 he became superintendent, surface-to-air guided weapons guidance systems. In this post he has been responsible for research on new guidance techniques which now form the basis of the future systems for the air defence of the United Kingdom and the field army. He has also been responsible for the development of tracking radars and other components of the systems and for the technical co-ordination of the complete systems.

The Central Botanical Laboratory, Allahabad :

Dr. E. K. Janaki Ammal

Dr. E. K. Janaki Ammal retired from the post of director of the Central Botanical Laboratory, Botanical Survey of India, Allahabad, on October 13, 1959. Dr. Janaki Ammal has been intimately associated with the reorganization of the Botanical Survey of India, first as officer on special duty (1952–53) and as director, Central Botanical Laboratory. Dr. Ammal is widely known for the "Chromosome Atlas of Cultivated Plants" which she compiled with Dr. C. D. Darlington. She is at present officer on special duty, Regional Research Laboratory, Jammu (in Kashmir State).

Dr. G. S. Puri

Dr. G. S. Puri has been appointed director of the Central Botanical Laboratory, Allahabad, in succession to Dr. E. K. Janaki Ammal. Dr. Puri has had a varied experience during his past twenty-five years of botanical career. He has done work of international recognition in palæobotany, phytogeography and ecology, and had the privilege of working with Prof. Birbal Sahni at Lucknow and Prof. W. H. Pearsall at London. He was forest ecologist at the Forest Research Institute, Dehra Dun, for about ten years and during the past three years as regional botanist of the Western Circle of the Botanical Survey of India he completed a reconnaissance survey of the vegetation of western India. Dr. Puri has published about 200 botanical papers, including two major books, the "Indian Manual of Plant Ecology" and "Forest Ecology".

The Australian Academy of Science

The following new Fellows of the Australian Academy of Science have recently been elected: Prof. A. E. Alexander, professor of applied chemistry, University of New South Wales; Prof. G. M. Badger, professor of organic chemistry, University of Adelaide; Dr. S. Fazekas de St. Groth, reader in virology, John Curtin School of Medical Research, Australian National University; Prof. K. J. Le-Couteur, professor of theoretical physics, Research School of Physical Sciences, Australian National University; Dr. J. M. Rendel, chief of the Division of Animal Genetics, Commonwealth Scientific and Industrial Research Organization; Dr. F. W. G. White, chairman of the Commonwealth Scientific and Industrial Research Organization.

The Thomas Ranken Lyle Medal for 1959 was presented to Prof. E. S. Barnes, professor of mathematics in the University of Adelaide, who delivered an address on number theory, his special field of work in mathematics.

Awards of the Meldola Medal for 1959

The Meldola Medal, which is the gift of the Society of Maccabaeans, is normally awarded annually. On four occasions in the past, two candidates have been adjudged to be of equal merit in diverse fields of work and two awards were made. This year it has again been decided to make two awards of the Meldola Medal. The recipients will be Dr. J. I. G. Cadogan, Department of Chemistry, King's College, London, for his work in the field of organic chemistry, with special reference to reactions of free radicals in solution and to reactions of organophosphorus compounds; and Dr. T. C. Waddington, Department of Chemistry, University of Cambridge, for his work in the fields of physical and inorganic chemistry, with special reference to thermochemistry and reactivity of azides; photoconductivity of anthracene; lattice energies and infra-red spectra of inorganic salts; and liquid hydrogen chloride as an ionizing solvent.

The Food Research Advisory Committee

Mr. J. B. Godber, Joint Parliamentary Secretary to the Ministry of Agriculture, Fisheries and Food, recently stated that the Minister and the Secretary of State for Scotland had set up a committee, under the chairmanship of the Permanent Secretary of the Ministry of Agriculture, Fisheries and Food, to assist them in advising the Agricultural Research Council on priorities in Government food research. This was in a written answer to a question in the House of Commons as to the arrangements for ensuring that the technical problems of the food industry are brought to the notice of the Agricultural Research Council now that the Council is responsible for the three Government research stations concerned with the handling and processing of foodstuffs. The Committee would be known as the Food Research Advisory Committee and its terms of reference would be: "To advise on those food problems (except for fish, which is dealt with separately) requiring investigation or research which should be undertaken with the aid of public funds and to make recommendations as to the priorities to be accorded to such problems". In addition to the chairman, Mr. E. Capstick, Dr. D. P. Cuthbertson, Sir Charles Dodds, Mr. J. D. Hutchison, Mr. D. Lowe, Mr. A. Sainsbury, Sir William Slater, Dr. J. A. B. Smith, Mr. T. A. H. Sycamore, Mr. J. P. Van den Bergh, Sir George Wilson and Mr. N. Wood had accepted invitations to be members of the Committee.

Ford Research Fellowships in Animal Reproduction

The Ford Foundation has made a grant of 550,000 dollars (£196,000) to the Zoological Society of London to endow a series of research fellowships in animal reproduction. Our present knowledge of reproductive processes is derived mainly from observations on a limited number of species, such as rats, mice, rabbits, guinea pigs, monkeys, and farm animals; but it is sufficient to show that there is great diversity in reproductive mechanisms. We know that some species are continuous breeders and that others are seasonal; that some animals ovulate spontaneously and that others do so only as a result of various forms of external stimulation. These differences have always served as pointers to research, which has in turn revealed issues which are vitally important to the control of reproduction. The animal collections maintained by the Society at Regent's Park and Whipsnade constitute the richest assemblies of living vertebrates in the world, and the Society also has in its possession breeding records which go back to the year 1828. The resources of the Society, however, have never been sufficient to promote a proper and continuing investigation of breeding behaviour.

Those appointed to the research fellowships, of which there will be six—three senior and three junior fellowships—will be expected to undertake systematic studies of the reproductive habits and the physiology of animals. It is hoped that they will have a secondary attachment to a university department or to a research institute in which reproductive physiology is a major research interest. Laboratories will be provided at Regent's Park by the Zoological Society, and a Breeding Research Committee, including British scientists who are in the forefront of research into reproductive physiology, has been established to supervise the work. Among those serving on the Committee are Prof. E. C. Amoroso, Prof. F. W. Rogers-Brambell, Prof. A. St. G. Huggett and Dr. A. S. Parkes.

The Beit Memorial Fellowships

THE trustees of the Beit Memorial Fellowships for medical research have announced the following elections: *Junior Fellowships* (£900 *a year*), D. C. Watts, to study the mechanism of enzymes in muscle from animals of various species and especially the role of the sulphydryl groups thought to be necessary for enzyme activity (at the Department of Biochemistry, University College, London); J. R. Casley-Smith, to investigate the ultra-structure and properties of the endothelium of lymphatics, in health and disease, with special reference to dropsy (at the Sir William Dunn School of Pathology, Oxford); P. F. Fottrell, to investigate the mechanism of adaptive enzyme formation in normal and malignant animal cells maintained in tissue culture (at the Tissue Culture Laboratory, Biochemistry Department, University of Glasgow); A. J. Rowe, to study the properties of the contractile muscle protein myosin, by means of the electron microscope (at the Department of Colloid Science, Cambridge); Dr. G. F. V. Seaman, to study the relationship between the chemical composition of the human red blood corpuscle membrane and its electrokinetic charge as determined by microelectrophoresis (at the Department of Medicine, Cambridge). *Senior Fellowship* (£1,300 *a year*), Dr. J. R. Tata, to purify and isolate thyroxine dehalogenase from various tissues and to investigate the relationship between metabolic transformation of thyroid hormones and their action in an isolated system (at the National Institute for Medical Research, Mill Hill, London).

Paul Instrument Fund Awards

AWARDS of grants by the Paul Instrument Fund Committee have been made as follows: £2,500, with the probability of further grants totalling up to £3,000, to Dr. J. H. Sanders, university lecturer and demonstrator in physics, Clarendon Laboratory, Oxford, for the construction of an optical maser; £3,000 to Mr. H. W. Gosling, lecturer in the Department of Engineering, University College of Swansea, for the construction of an instrument for checking the stability of the standard ampere. The Paul Instrument Fund Committee, composed of representatives of the Royal Society, Physical Society, Institute of Physics and Institution of Electrical Engineers, was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much improved types of physical instruments and apparatus for investigations in pure or applied physical science".

Co-operative Research in Europe

A SHORT article, "O.E.E.C. and the Scientific Future", in the February issue of *European Productivity* notes some of the ways in which the Organization for European Economic Co-operation has been strengthening the scientific resources of Europe. First, the Organization is pursuing an inquiry into the scientific policies of member countries and their research resources, such as a study of fiscal measures which influence investment in industrial research. Secondly, co-operative research is in progress on fatigue failure in metals and the fouling of ships' hulls; representatives from Sweden and Yugoslavia joined the group of experts this year and the adhesion of Yugoslavia will make it possible to secure a better picture of fouling organisms in Mediterranean waters. Tests are still being made in Europe, Australia, North America, South Africa and Singapore, and a catalogue of the biological and hydrological characteristics of the testing stations in use will be published. Experts from nine European countries and the United States have met to plan co-operative research into aircraft noise and have recommended free exchange of all available information on aircraft noise and its effects, particularly its biological effects on people living near airports. A permanent group has been set up to advise the Committee on Applied Research on the long-term development of research into the abatement of aircraft noise. A group of nine member countries dealing with fire research is proposing to study unstable chemicals for plastics and also fire-fighting techniques and materials, while other work is in hand on the industrial utilization of oil-shale fires, the measurement of air pollution, static electricity in industrial tools, road safety and production engineering techniques. Thirdly, attention is being given to the supply of scientific and technical personnel in relation to Europe's economic needs, including such matters as the use of television in science teaching, and methods of teaching mathematics in schools.

British Library of Political and Economic Science

THE annual report of the British Library of Political and Economic Science for 1958–59 records little change in the funds available for purchase or in book prices; but acquisitions of Russian publications were slightly lower than in 1957–58 and were facilitated by exchange arrangements with the Saltykor-Shchedrin Public Library, Leningrad, the Lenin Library, Moscow, and the All-Union Library of Foreign Literature (pp. 16. London: British Library of Political and Economic Science, 1959). Additions during the year included 5,330 treatises, 1,510 pamphlets, 2,386 non-serial government publications and 8,235 current serials, including 5,913 periodical titles received as gifts from governments, municipalities, institutions and societies. Of the Library's total holdings of 401,752 bound volumes, 12,137 were in the Lending Library and 4,674 in the Shaw Library.

The Manchester Museum

The annual report of the Manchester Museum for 1958–59 records that the year has been notable for the continuation of the policy of the Committee to modernize display and provide showcases with internal lighting, the receipt of a number of valuable acquisitions including the Raby collection of coins and the Armstrong collection of bones and artefacts from Pin Hole Cave, Derbyshire, and the mounting of a series of exhibitions in the special gallery devoted to this purpose (pp. 20. Manchester: The Manchester Museum, The University, 1960). These latter included the R. W. Lloyd Japanese Collection and the Robinow Collection from ancient Egypt. During the year two departmental guides, devoted to ethnology and mammals, were published. It is also reported that the University has allocated certain funds for the conversion of the Archæological Balcony into a complete gallery, part of which can be used for the R. W. Lloyd Japanese material. The building programme of the University has made it possible for the Department of Zoology to relinquish the accommodation adjoining the Herbarium, and this is to be used for a much-needed botanical laboratory, an office and for storage.

Geological Surveying by Helicopter

Up to about 1950, after more than a century of effort, only about a third of Canada's 3·6 million square miles of land had been mapped geologically even on a reconnaissance scale. Conventional field work in increasingly remote regions was becoming prohibitively slow and costly, and insufficient trained geologists were available to carry out intensive pioneer explorations comparable to the all-out Russian efforts in Siberia. Clearly a radically new field technique was required to meet the urgent need for geological exploration, development and exploitation in the north. In a recent publication officers of the Geological Survey describe how this new technique has been found in the widespread use of helicopters (Canada: Department of Mines and Technical Surveys. Geological Survey of Canada. Bulletin No. 54: Helicopter Operations of the Geological Survey of Canada. By Officers of the Geological Survey of Canada. Pp. xii+60+7 plates. (Ottawa: Queen's Printer, 1959.) 75 cents). Seven major helicopter-supported geological surveys, instituted as experiments between 1952 and 1958, have covered close on half a million square miles—half as much ground as had been mapped in the previous 110 years. While these helicopter operations have afforded maps on the scale of 1 in. to 8 miles (1 : 506,880) instead of the 1 in. to 4 miles common in conventional reconnaissance, they have given more uniform coverage and more speedy results at an operating cost (in the region of 1·68–3·63 dollars per square mile) less than that of any other field method known. The rapid progress is indeed remarkable; but Canada still has some considerable way to go before it overtakes the U.S.S.R., now almost completely mapped on scales of between 1 : 500,000 and 1 : 1,000,000, and producing on a scale of 1 : 200,000 between 120 and 150 map-sheets per annum.

Fate of Bacteria in the Small Intestine

Recent work carried out by J. M. S. Dixon, of the Public Health Laboratory, Cardiff, confirms the view that the empty small intestine of healthy persons contains only a few transient organisms, even when free acid is absent from the stomach (*J. Path. and Bact.*, 79, No. 1; January 1960). The small gut appears to possess some antibacterial mechanism causing organisms that escape destruction in the stomach to be either destroyed or removed from the lumen before they can multiply. There has been some disagreement as to whether the small intestine is relatively free from organisms because of destruction of bacteria within the lumen or because peristaltic activity removes the bacteria before they can multiply. The *in vivo* experiments were designed to elucidate this point. Test organisms were inoculated directly into subcutaneously displaced loops of small intestine of non-anæsthetized rats together with an inert unabsorbable marker. The animals were killed after periods of time and the number of bacteria and quantity of marker present in regions of the small gut determined. The marker used was a radioactive isotope of chromium which, when tagged to red blood cells, is virtually unabsorbed from the intestine. The results of twenty-eight bacterial inoculations indicated that bacteria were rapidly moved onward and soon removed from the small intestine by peristaltic action. There was no indication of bactericidal action. Mechanical removal by peristaltic action, aided by the secretion of mucus, is probably the main fate of viable organisms that enter the small intestine.

Cave-dwelling Shrimps

The Australian Museum announces that it has acquired from the Milyering district, Western Australia, some freshwater shrimps of considerable interest to zoologists (*Aust. Mus. Mag.*, 13, No. 3; 1959). The specimens were collected by Mr. A. Snell, of Bunbury, West Australia, in the dark recesses of a well bored through coral and limestone country. The shrimps lack sight and have been identified as true troglodic (cave-dwelling) forms—the first to be recognized from the Australian continent, and not previously recorded. The task of providing the shrimps with a zoological name and preparing a description of them for publication in the *Records of the Australian Museum* is being undertaken by Dr. Lipke Holthuis, of the Leyden Museum, Holland.

Large Pine Weevil

The first of the leaflets published by the Forestry Commission has now been issued in revised form and illustrated with attractive colours (Forestry Commission Leaflet No. 1: The Large Pine Weevil (*Hylobius abietis*). Revised edition. Pp. 11. London: H.M. Stationery Office, 1960. 1*s*.). It deals with the large pine weevil, *Hylobius abietis* L., which is the only species of the genus *Hylobius* of importance in coniferous forests in Britain. It feeds on the bark of young coniferous trees, and, where it is unduly numerous, may cause the complete loss of a newly planted crop. Recent trials, both in Great Britain and abroad, have shown that it is possible to provide protection to young crops by the direct application of various insecticides. Two possible situations may arise—that in which the weevil attack is anticipated, and that in which the weevil attack occurs unexpectedly. In the former case, the dipping of planting stock before planting out should be used; but in the latter the young crop should be sprayed as soon as the attack develops. With both types of treatment the insecticide recommended for use is DDT. The main factor controlling the numbers of *Hylobius* is the availability of suitable breeding sites. When breeding grounds are provided by fellings or by natural catastrophes such as fire or wind-blow, numbers inevitably rise. Some control of weevil increase is afforded by insect parasites, such as *Bracon hylobii* Ratz. and *Ephialtes tuberculatus* Geoff. in Four., by fungal attack on larvæ and possibly by birds. Generally, this natural control is unable to keep populations below a density at which they can cause serious damage to young conifer crops.

The Nucleus in a Basidiomycete

A. BAKERSPIGEL has given a detailed account, with numerous photographic illustrations, of the structure and manner of division of vegetative hyphal nuclei in *Schizophyllum commune* (*Canad. J. Bot.*, 37, No. 5, 835; 1959). These nuclei do not divide in a manner directly comparable to ordinary mitosis. During division the tightly packed chromatinic granules become loosely arranged, after which they contract into a densely stained bar. As division proceeds, this bar of chromatin elongates and then constricts at its mid-region. At the end of division the extremities pull apart quickly to form the chromatin portions of the two sister nuclei. The Feulgen-negative central bodies decrease in size, and at the end of division their remnants lie free in the cytoplasm. New central bodies arise in the maturing sister nuclei. Throughout division, metaphase plates, spindles, or individual chromosomes were not observed in any of the stained or living preparations. A nuclear membrane has not been observed surrounding any of these nuclei.

Anchiceratops from Alberta

A NATURAL history paper by Mr. Wann Langston, jun. (No. 3; September 23, 1959), published by the National Museum of Canada, deals with specimens of *Anchiceratops* from the Oldman formation of Alberta. This is an Upper Cretaceous bed, and the material was collected by a National Museum expedition of 1937. The paper describes fully the specimens in the Museum and discusses the habitat of *Anchiceratops* and the characteristics of the sediments in which they are found.

Miniature Gyroscopes

IN the first of a series of articles devoted to micro-instruments, W. R. Simons of Smiths Aircraft Instruments Ltd., describes the use of miniature gyroscopes in aircraft and guided missiles (*Research for Industry*, 13, No. 2; February, 1960). The special requirements of guided missile control systems and recent developments in the design of aircraft auto-pilots have created a demand for miniaturized gyroscopes, possessing high accuracy together with exceptional reliability and robustness. Some of the fundamental problems associated with the design of these miniature gyroscopes are discussed and typical examples of the instruments are described.

Bibliography on Plasma Physics and Magnetohydrodynamics

THOUGH the subject of magnetohydrodynamics dates back to the nineteenth century, it is primarily in the past two decades that it has attracted wide attention. Its importance, first recognized in astrophysics, has spread to many fields, particularly the study of the flow of gases and the appearance of ionization, and the phenomena presented by completely ionized plasmas at extremely high temperatures. The literature on the subject has increased at a rapid rate, and we are indebted to J. D. Ramer, of the Engineering and Physical Sciences Library of the University of Maryland, for the collection of literature of the period 1937–59 which he has compiled (Bibliography on Plasma Physics and Magnetohydrodynamics and their Applications to Controlled Thermonuclear Reactions. Pp. ii + 105. College Park, Maryland: Engineering and Physical Sciences Library, University of Maryland, 1959). The bibliography contains 1,707 references arranged alphabetically by authors. In general, the titles of the papers are given in English, but the language of the original article is quoted. The author index seems superfluous (it covers twelve pages), but together with the numerical index to Atomic Energy Reports (five pages) and the alphabetical list of journals referred to in the bibliography (four pages) which complete the volume, it gives an excellent impression of the wide and useful coverage of the bibliography.

Scholarships in Chemical Engineering

CONSTRUCTORS John Brown, Ltd., have entered into an agreement with the Institution of Chemical Engineers for the award of two scholarships. The purpose of the scholarships is to encourage research in chemical engineering and, in particular, in chemical plant design. The scholarships are tenable at any educational institution in the United Kingdom in receipt of grants from the University Grants Committee, and having a department of chemical engineering under the direction of a professor of chemical engineering. Further information can be obtained from Dr. J. B. Brennan, Institution of Chemical Engineers, 16 Belgrave Square, London, S.W.1. Applications should reach the Institution not later than June 1.

University News:

Birmingham

THE following appointments to lectureships have been made: Dr. G. H. Burkhardt (mathematical physics); Dr. D. C. Champeney (physics); Mr. D. A. O'Connor (physics); Dr. M. J. Lawrence (genetics); Mr. G. H. Trengrouse (mechanical engineering); and Mr. E. Amini (mechanical engineering).

Edinburgh

A CHAIR of electrical engineering has been instituted in the University of Edinburgh and applications for appointment to it will shortly be invited.

London

DR. K. W. CROSS, reader in physiology at St. Mary's Hospital Medical School, has been appointed to the University chair of physiology tenable at the London Hospital Medical College. Dr. B. C. L. Weeden, reader in organic chemistry at the Imperial College of Science and Technology, has been appointed to the University chair of organic chemistry tenable at Queen Mary College. Dr. D. V. Ager, lecturer in geology at the Imperial College of Science and Technology, has been appointed to the University readership in geology tenable at that College. The title of reader in the history and philosophy of science in the University of London has been conferred on Dr. N. H. de V. Heathcote in respect of his post at University College.

The following elections to fellowships of the Imperial College of Science and Technology have been made: Sir Harold Roxbee Cox, director, Wilmot Breeden (Holdings), Ltd., the Metal Box Company, etc., former special lecturer in aircraft structures;

Prof. C. W. Dannatt, professor emeritus, former professor of metallurgy and former dean of the Royal School of Mines; Prof. F. G. Gregory, professor emeritus and former professor of plant physiology; Mr. G. C. Lowry, former secretary of the College; and Sir William Pugh, director of the Geological Survey and Museum, member of the Governing Body.

Announcements

Mr. J. B. Adams, at present director of the Proton Synchrotron Division of the European Organization for Nuclear Research (CERN), has been appointed interim director-general of the Organization; this appointment became necessary as the result of the recent death in an aeroplane accident of Prof. C. J. Bakker. Mr. Adams was recently appointed director of the new Controlled Thermonuclear Research Establishment in the United Kingdom, but will remain with CERN until later this year.

Dr. W. F. Floyd, senior lecturer in physiology at the Middlesex Hospital Medical School, University of London, has been appointed to be first head of the Department of Ergonomics and Cybernetics at Loughborough College of Technology. Dr. Floyd will assume his appointment at Loughborough in September.

Dr. H. D. Kay, director of Twyford Laboratories, Ltd., Twyford Abbey Road, London, N.W.10, announces the following appointments: Microbiology Section, Dr. C. Elizabeth Work, who has carried out research in the Department of Chemical Pathology, University College Hospital Medical School, London; Dr. Work will be assisted by Dr. V. A. Knivett, formerly of the Microbiology Section of the National Chemical Laboratory (Department of Scientific and Industrial Research), Teddington. Biochemistry Section, Dr. J. Leggett Bailey, recently at the Rowett Research Institute, Aberdeen; he will be assisted by Dr. R. J. Sturgeon, of the Research and Development Department at Epsom of the Distillers Company, Ltd.

The sixth annual Guenter Loeser Memorial Lecture will be given by Dr. Hans E. Hinteregger on "Solar Extreme Ultra-violet Radiation as a Source of Interplanetary Ionization". The Lecture, organized by the U.S. Geophysical Research Directorate, will be given in the Lexington High School Auditorium, Lexington, Massachusetts, on June 1. Further information can be obtained from Arnold M. McCalmont, Geophysical Research Directorate, Air Force Cambridge Research Center, Bedford, Mass.

There will be open days at the National Physical Laboratory, Teddington, on May 25 and 26. The new Ship Hydrodynamics Laboratory at Feltham (see *Nature*, 184, 926; 1959) will be open to inspection for the first time.

The seventy-fifth anniversary exhibition of the Royal Scottish Geographical Society, entitled "Mapping Britain", is being held in the Royal Scottish Museum, Chambers Street, Edinburgh, during May 14–June 25. Further information can be obtained from the Secretary of the Society at Synod Hall, Castle Terrace, Edinburgh 1.

The second Congress on Catalysis is to be held in Paris during July 4–9. Further information can be obtained from Prof. G. Emschwiller, 10 rue Vauquelin, Paris 5°.

The eleventh International Astronautical Congress is to be held in Stockholm during August 15–20 under the auspices of the Swedish Interplanetary Society. Further information can be obtained from the Congress Information and Publicity Committee, *IAF*-60, Box 5045, Stockholm 5, Sweden.

An International Conference on Scientific Problems of Crop Protection, sponsored by the Hungarian Academy of Sciences, will be held in Budapest during July 19–22. Further information can be obtained from Z. Király, Research Institute for Plant Protection, Budapest.

An International Congress on Photobiology is to be held in Copenhagen during July 31–August 5 under the auspices of the International Committee of Photobiology. Further information can be obtained from Dr. B. Chr. Christensen, Finsen Memorial Hospital, Strandboulevard 49, Copenhagen Ø.

The sixth Commonwealth Conference on Mycology will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1, during July 15–23. Further information can be obtained from the Commonwealth Mycological Institute, Ferry Lane, Kew, Surrey.

The fourth International Conference on Goitre is to be held at Church House, Great Smith Street, London, S.W.1, during July 5–9. Further information can be obtained from the honorary secretary, Dr. Selwyn Taylor, 67c New Bond Street, London, W.1.

A conference on heat treatment practice, organized by the British Iron and Steel Research Association, will be held at Harrogate during July 5–6. Further details can be obtained from the Technical Secretary, Metallurgy (General) Division, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

An International Congress of Endocrinology, the first of its kind, is to be held in Copenhagen during July 18–23. Further information can be obtained from the Congress Secretariat, Dr. Svend G. Johnsen, Hormone Department, Statens Seruminstitut, Copenhagen S, or the general secretary, Prof. F. T. G. Prunty, Department of Chemical Pathology, St. Thomas's Hospital Medical School, London, S.E.1.

The annual meeting and summer conference of the Society for Applied Bacteriology will be held at Bangor during July 5–7. Further information can be obtained from Dr. Ella M. Barnes, Low Temperature Research Station, Downing Street, Cambridge.

The third International Conference on Medical Electronics and associated scientific exhibition are to be held at Olympia, London, during July 21–27. The conference is being organized jointly by the Electronics and Communications Section of the Institution of Electrical Engineers and the International Federation for Medical Electronics. Further information can be obtained from the Conference Secretariat, Institution of Electrical Engineers, Savoy Place, London, W.C.2.

A new list of medical and technical papers prepared by research workers has just been issued by Cyanamid International in London. The current range of subjects covers the trial administration of Lederle Laboratories' oral polio vaccine in many different countries and papers on specialty industrial chemicals. These paper are available from the Cyanamid International Information Service, 16 Bolton Street, London, W.1.

INHALED PARTICLES AND VAPOURS

THE British Occupational Hygiene Society held an international symposium under this title at Oxford, during March 29–April 1, when 38 papers were read. Inhalation of foreign substances in the atmosphere has never before been discussed on such a scale, and the gathering of 250 scientists from 19 nations enjoyed a unique presentation of most of the basic and a few of the applied aspects of the subject.

Six of the papers dealt with the deposition, translocation and effects of radioactive particles.

Papers on the mechanics of breathing included a study of maximal flow-rates, a consideration in designing respiratory equipment, and a demonstration that turbulent flow could be detected at the exit of a segmental bronchus with high air-flow. During gentle breathing the larynx probably causes some turbulence which is passed down the trachea when inhaling; even at high rates turbulence is not fully developed and cross-stream mixing is far from complete.

The mixing of tidal and alveolar air had been investigated with a half-micron aerosol as a tracer. The particles in this have practically no diffusion constant, and no rate of fall, so that they follow the mechanical movements of inspired air and reveal, by wash-in and wash-out analyses, the gas-phase exchange properties of the lung which cannot be demonstrated by even high molecular weight gases since they diffuse too quickly. This exchange is important in the deposition of aerosols in the lungs, which is further complicated by the desirability of distinguishing alveolar from bronchial epithelial deposition since only the former contributes to the pneumoconioses.

Previous approaches to the problem have been made by calculating the motion of particles in the airways; a formalized anatomy of the human lung for use in such calculations, and in expressing the fluid mechanics of gas-flow, was put forward at the meeting.

The loss of particles during inhalation was shown to be affected by their increase in size by absorbing moisture, while passing through the respiratory tract, which also results in their being less likely to penetrate deeply. Tobacco smoke has a high retention, in view of its initial particle size, for this reason, and sodium chloride crystals increase about 350 times in volume.

Sulphuric acid droplets behave similarly and are important in atmospheric pollution. The oxidation of sulphur dioxide, which dissolves rapidly in aqueous droplets, is promoted catalytically by trace contaminants in the liquid phase, and may be a factor in the relationship of atmospheric sulphur to human respiratory distress.

An increase in the response of guinea pigs to irritant gas, expressed as a rise in respiratory resistance measured with an intrapleural catheter, referred to tidal volume indicated by a body plethysmograph, was found to result when an inert aerosol of sodium chloride was inhaled along with sulphur dioxide or formaldehyde. The particle size had to be around 0·1μ in diameter, 2·5μ aerosol giving no potentiation. A physical explanation was advanced for this effect, based on the absorption of the gas by the particles so that the uptake on respiration was localized at discrete places on the bronchial surface instead of being diluted over a large area. This observation has not yet been confirmed in man.

The absorption of vapours during inhalation is subject to three possible rate-determining factors which can be expressed as a simple mathematical model. They comprise the rate of lung ventilation, the diffusion capacity across the lung wall, that is the gas-liquid boundary, and the rate of flow of the pulmonary blood allowing for the air–water partition coefficient of the foreign gas.

According to circumstances one or other of these factors predominates to control the build-up in tissue during exposure and the subsequent drainage, when the breathing of pure air is resumed. The three main storage depots recognized are viscera, connective tissue including skin and muscle, and body fat, between which the flow of blood is apportioned in the ratios 73 : 24 : 3. Allowing for tissue mass and fat–water partition it can be shown, in contrast to carbon monoxide, which is all held in the blood, that nitrogen is stored and that the equilibration-rate for fat is very slow so that a reservoir is formed and may result in the initiation of caisson disease.

A soluble vapour was shown, in experiments on the uptake of inhaled sarin (*iso*propylmethylphosphonofluoridate) in animals and man, to be absorbed in the nose and in the mouth and throat at low rates of oral inhalation; at high rates it penetrated to the lungs. Human nasal retention of particles was found to be practically complete at 9μ diameter, falling to 10–20 per cent at 0·4μ. The reason for this appreciable retention at the small size is obscure. Ammonia and iodine were entirely absorbed in the nose.

The elimination of dust deposited in the acinus of the animal lung was the subject of several papers. Some dust is eliminated via the ciliated epithelium while the rest penetrates the interstitial tissue and may reach the lymphatics. The view was put forward that phagocytes originating from the alveolar wall are responsible for the carriage of dust from the acinus to the mucus escalator which ends at the base of the terminal bronchioles, each of which feeds an acinus, the latter constituting the basic respiratory units of the lung. Only free, not phagocyted particles could enter the interstitium, the route being by means of the transition region between the acinus and the terminal bronchiole; the pick-up by the mucus escalator from the respiratory bronchioles is regarded as being incompletely effective.

Experiments were described showing that elimination from the alveoli is a slow and continuous process. The proportion of deposited dust following the lymphatic route depended on the kind of dust, and repetition of exposure stimulated elimination and mobilized existing dust deposits. Experiments on exposures to red and black dusts, with a time-interval between, proved that dust was conveyed, probably by phagocytes, to collection sites around the air passages and that these foci were not static structures, but the particles continually shifted about, as could be explained by the repeated death of dust-laden phagocytes with release of their burden, which was then incorporated by new cells.

After a single administration of dust, phagocyte counts in saline washed into and out of rat lungs demonstrated that the number of cells was related to the quantity of dust eliminated. The half-life of this phase of elimination by phagocytosis to the bronchial epithelium was about 17 hr. The proportion of dust eliminated in this way depended on the nature of the dust, but the time-constant did not; it did not appear to matter whether the dust was given by inhalation or by intratracheal injection.

Another series of experiments confirmed the destructive action of silica dusts on macrophages and once again led to the suggestion that the damage inflicted on the cells is the first step in the chain of causation of silicosis. The effect is believed not to be cytotoxic, but to comprise an activation either of a serum complement absorbed on the outside of the cells or of an enzyme, possibly a non-specific esterase, within the cells.

Examination of lung residues from 50 asbestosis cases was reported, with the conclusion that a fibrogenic agent was liberated when asbestos bodies break up. The deposition of an asbestos fibre in lung tissue is followed by its becoming enclosed in a protein sheath which passes through a sequence of changes and finally segments, after 10–15 years, with fracture of the contained fibre. The fragments of the sheath are collected by interstitial macrophages and fibrosis is marked in regions where this occurs. The time sequence of clinical events and of lung content of fibres exceeding 26μ in length supports the argument.

Papers on dust-sampling included the description of an ingenious centrifugal device called the 'conicycle', which collects only particles between upper and lower limits of falling speed. It has been engineered as a practical sampling tool for coal mines and is being tried out underground.

The relationship between the acceptance curve of a sampling instrument designed to control dust conditions relevant to the incidence of pneumoconiosis, and the actual deposition–particle-size curve of the human respiratory tract was given more emphasis by the engineers than our crude and incomplete knowledge of the latter can possibly justify.

Arguments in favour of selecting finer particles than the 50 per cent at 5μ diameter and unit density, which at present forms the basis of British selective sampling practice, are therefore poorly based. The opposite view was also put forward, that all dust should be sampled, irrespective of particle size; besides being physically impossible this would encourage the collection of large quantities of coarse dust which has no conceivable bearing on pneumoconiosis because, when inhaled, it would not penetrate beyond the bronchi, and larger bronchioles.

The papers and discussions will be published by Pergamon Press in due course.

C. N. Davies

CARDIOVASCULAR EFFECTS OF NICOTINE AND OF SMOKING

During March 23–25 a symposium on the Cardiovascular Effects of Nicotine and of Smoking was held by the New York Academy of Sciences. The papers presented covered more than the cardiovascular effects and included other interesting observations. For example, nicotine is found not only in the tobacco plant, but it also occurs widely in the plant kingdom. It is produced in the root system of the tobacco plant, and the growth of the roots is very closely related to the rate of nicotine production, from which R. F. Dawson (Columbia) and his colleagues conclude that the same reaction step limits both processes. Nicotine arises from the precursors nicotinic acid and ornithine. From the root it is transported primarily to the leaves, where it accumulates during the active life of the plant. It is believed to be a terminal product with no appreciable physiological activity for the plant. Such a conclusion seems to an animal physiologist to be highly unlikely.

Nicotine is absorbed not only by those who smoke but also by those who take snuff and those who chew tobacco. The figures given for the amount of nicotine absorbed when smoking one cigarette vary according to the degree to which smoke is inhaled. They range from estimates as low as 0·3 mgm. to others as high as 1·8 mgm. Since the intravenous injection of 0·7 mgm. nicotine (base) produces unpleasant symptoms, the higher figures must be regarded with doubt.

Nicotine taken in the form of snuff has been estimated to amount to 20–60 mgm. a day, and that absorbed as a result of chewing has been estimated as 10–90 mgm. a day (Larsen, Richmond, Virginia). It is obvious that the taking of snuff and the chewing of tobacco offer much less risk of producing cancer of the lung.

The metabolism of nicotine is not yet fully known, and further work is badly needed. Nicotine is found in the urine excreted unchanged, together with related substances (McKennis, Richmond, Virginia). Oxidation of the pyrrolidine ring appears to be a major step. The lactam (−)-cotinine which arises from the metabolism of (−)-nicotine is oxidized, and in the dog there is hydroxylation and methylation. It seems possible that the metabolism of nicotine changes with advancing years, some processes declining in rate or ceasing altogether. If the toleration of nicotine depends on a high rate of breakdown, the observation that some older people stop smoking who smoked much when young may depend on such a decline.

Nicotine has been known to cause poisoning in those using it as an insecticide. Travell (Cornell) has shown that its absorption through the skin is greatly affected by the *p*H of the solution. At a *p*H of 5·0 or less it is very little absorbed, but at an alkaline *p*H it is readily absorbed. This holds true for the membrane of the stomach and of the bladder. Nicotine excreted in the urine may be absorbed from the bladder into the blood if the urine is alkaline, and may produce toxic effects. The speed of absorption depends on the concentration of free base. On the cardiovascular system, nicotine has long been believed to owe its action to stimulation of the autonomic ganglia. Langley applied nicotine to ganglia in order to determine the effect of stimulating the cells present in the ganglia. Recently, attention has been directed to various peripheral effects of nicotine at sites where ganglia are not present. Thus, nicotine has a two-fold effect in the isolated heart. It causes first inhibition of contractions, and second acceleration and augmentation. The inhibition is excluded in the presence of atropine, but the acceleration is unaffected. In the heart there is a store of noradrenaline which can be extracted from the heart. Hitherto the existence of this store has been neglected by physiologists. It is now evident that the acceleration of the heart caused by nicotine is due to the release of some of the noradrenaline from the store. This follows from the observation that when there is no store of noradrenaline, nicotine loses its accelerating action (Burn and Rand, Oxford). Treatment of the animal with reserpine causes a disappearance of the store at the end of a few hours. The rise in heart-rate which follows smoking is thus probably explained by an action of nicotine on the heart itself releasing noradrenaline from storage sites in the heart.

In 1940 it was shown by Grace Roth and her colleagues that when a person smoked a cigarette in a warm room there was a large fall in skin temperature. This fall was believed to result from a constriction of the skin vessels caused by a stream of impulses passing down the vasoconstrictor nerves. However,, observations have recently been made in the isolated ear of the rabbit, which contains no ganglia. These have shown that when the vessels of the ear are perfused with a modified Ringer's solution, the outflow being measured with a sensitive recorder, the injection of 3 μgm. of nicotine into the fluid about to enter the ear causes vasoconstriction. The outflow from the ear veins is greatly reduced. This action also appears to be due to the release of noradrenaline from a store present in the ear, either in the walls of the vessels or in tissue nearby. For if a rabbit is injected with reserpine on one day, and then killed on the following day, the noradrenaline which can be extracted from the skin of the ear has disappeared, and when the ear is perfused with Ringer's solution, nicotine no longer causes vasoconstriction. When the skin of such an ear is extracted, no noradrenaline is found present in it. Some individuals suffer from a disease called thrombo-angiitis obliterans which when active causes such a restriction of the circulation through the fingers that the tissues become dry and bloodless, and the finger tips may become gangrenous. The disease may be quiescent for long periods; but if the patient begins to smoke, the symptoms get worse and the disease becomes active. It seems likely that the effect of smoking is explained by nicotine releasing noradrenaline from the neighbourhood of the small vessels.

The exact site of storage of noradrenaline in the heart and in or near the vessels is unknown. There is a possibility that it is held in tissue known as chromaffin tissue. These are cells which stain brown with potassium dichromate; they form the greater part of the cells of the adrenal medulla. Such cells have long been known to occur among the fibres of the sympathetic system, and side by side with the sympathetic ganglion cells. They originate in the neural crest like the sympathomimetic ganglion cells and were called by Kohn "paraganglia" in 1903. Evidence is beginning to accumulate that the distribution of chromaffin cells is much wider. Busacchi in 1912 described a "paraganglion cardiacum" lying around the origins of the coronary arteries. Adams-Ray and Nordenstam (1956) have described such cells in human skin, and Leach believes that they may be present in the skin of the rabbit ear, in the skin of the cat's tail and in the nictitating membrane of the cat's eye. In all these situations nicotine exerts an action on the normal tissue. Thus, as already mentioned, nicotine causes constriction of the vessels of the rabbit ear; it also causes erection of the hair on the cat's tail, and finally it causes contraction of the nictitating membrane when isolated from the body and free from ganglia. Yet if an animal is previously treated with reserpine, and if in consequence all local stores of noradrenaline disappear, nicotine loses these actions, and all the chromaffin cells are lost. It may therefore be that nicotine exerts its peripheral effects by discharging noradrenaline from chromaffin cells. J. H. Burn

THE NEW ZEALAND ANTARCTIC EXPEDITION

In the thirty-third Thomas Cawthron Memorial Lecture, Sir Edmund Hillary described some of the experience gained by members of the New Zealand Antarctic Expedition (Cawthron Institute, Nelson, New Zealand. Thomas Cawthron Memorial Lecture No. 33 (1958): The New Zealand Antarctic Expedition. By Sir Edmund Hillary. Pp. 12+4 plates. Nelson: Cawthron Institute, 1959). Although, for economy, the expedition made use of Ferguson tractors, Sir Edmund records that, with three 'Snocats', the journey could have been done "with twice the comfort and in almost half the time".

Comparison of the buildings which have been traditionally used on British expeditions and the newer module type of construction shows the advantages to rest almost entirely with the latter.

The experience gained with the dog teams should be of value to other expeditions. At the base, the dogs lived primarily on seal meat supplemented by vitamin pills, although this was varied at times with tinned dog food. In the field lightness was of primary importance and here pemmican was used. There were two forms of pemmican. One was the standard 'Bovril' pemmican which has been used a great deal in the Antarctic and the Arctic. Long and strenuous trips have been made on this pemmican, but the literature on the subject is filled with criticisms of it and descriptions of the deterioration in dog health when it is used. The Expedition's experience with 'Bovril' pemmican was much the same—loss of condition and continual scouring. "It was very fortunate that we also had generous supplies of the second type of pemmican, which was based on a formula developed by Dr. Malcolm of the Otago Medical School for the Byrd Expedition". This pemmican proved to be an outstanding success and played an important part in the achievements of the dog teams. The formula is :

Meat meal	42 per cent
Tallow	40 ,,
Whole wheat meal	10 ,,
Wheat germ	5 ,,
Molasses	2 ,,
Cod liver oil	1 ,,

Sir Edmund Hillary indicates that dogs can still do a useful task in the Antarctic. The expedition made it clear that dogs cannot compete with vehicles when travelling long distances or hauling profitable payloads. While the average man can quickly adapt himself to driving a tractor in snow, a dog driver and his team need long and constant training and practice to reach a pitch of proficiency. Although the men did extremely well, at no stage could they have reached the standard of skill shown by the professional drivers in a party such as Amundsen's.

But a dog team is a mobile form of transport and can give useful support to a survey or geological party in rough or crevassed country. If the dog teams are airlifted to the area to be explored, and if they are kept supplied by air so that they can travel with reduced loads and so move briskly about, they are probably still the best form of transport for a close examination of the many great mountain ranges and glaciers which fringe the barren wastes of the polar plateau.

RADIOCÆSIUM AND POTASSIUM-40 IN NORWEGIAN-PRODUCED MILK

By K. MADSHUS and J. BAARLI
Norsk Hydro's Institute for Cancer Research, Oslo, Norway

THE radioactive isotopes cæsium-137 and strontium-90 represent a major part of the radiation hazard to man caused by nuclear explosions, by reason of their long half-lives (28 and 27 years, respectively). The rate of fall-out depends to a large extent on the geographical locality, and on the weather conditions at the relevant places of interest[1,2]. There is evidence that the northern hemisphere and places with high rate of precipitation[3] receive the highest fall-out. These conditions obviously hold for Norway.

The degree of hazard which the ionizing radiation represents to man can, in principle, be estimated in two ways. One method is to determine the amounts of the isotopes in foodstuffs, taking into account the discriminating factors involved during passage of the food through the human body. The other method is the direct measurement of radiation from the human body. Milk appears to be one of the main constituents of the human diet carrying the radioactive material from the ground into the human body.

The present work was undertaken to obtain as reliable information as possible about the concentration of cæsium-137 in Norwegian-produced milk. This isotope is most important in view of the genetic effects of its γ-radiation ($E_\gamma = 660$ keV.), compared with the more localized damage caused by the β-radiation from strontium-90 ($E_\beta = 0{\cdot}61$ MeV.).

It seems an established fact[4] that the fall-out ratio strontium-90/cæsium-137 from atom-bomb debris is nearly constant. This is not only the case for soil and rain-water; milk samples collected within the same districts also show the same tendency[5]. As the experimental determination of cæsium-137 is a rapid process compared with the more laborious determination of strontium-90, the content of cæsium-137 can serve as a quick monitor of the rate of strontium-90 fall-out.

The equipment used for studies of low-level γ-radiation has been described elsewhere[6]. It is composed of a heavily shielded scintillation detector, consisting of a sodium iodide (thallium) crystal 2¼ in. diameter × 3 in. and a Du Mont 6363 phototube in connexion with an R.C.L. 256-channel pulse-height analyser. A cross-section of the equipment is shown in Fig. 1. The background radiation in the measuring space of this equipment is found to be 212 ± 1·0 counts/min. in the energy-range 80–1,700 keV. The background, in the two pulse-height regions of special interest to the present study, is 14·1 ± 0·1 counts/min. in the cæsium-137 photopeak range, and 5·3 ± 0·1 counts/min. in the potassium-40 peak. The position of the photopeak in the pulse-height spectrum is stable over a long period, being 0·75 per cent after the initial warm-up. The equipment has been calibrated using dried milk with a known concentration of cæsium-137 and potassium-40. The samples were canned in metallic containers, each holding 250 gm. of dried milk. We are much indebted to Dr. D. V. Booker, of the Atomic Energy Research Establishment, Harwell, for supplying us with several of his measured samples used here for calibration purposes.

Two kinds of standards were used, one containing full-cream dried milk, and the other skimmed dried milk. The calibration samples contained 670 pc./kgm. and 485 pc./kgm. of cæsium-137 (1 pc. = 10^{-12} curie) with a potassium content of 14·9 and 17·6 gm./kgm. for the skimmed milk, and 445 pc. cæsium-137/kgm. and 11·2 gm./kgm. for the full-cream dried milk.

Dried skimmed milk and full-cream dried milk were obtained from a dairy receiving milk from districts in the Trõndelag and Hedmark counties. The former county lies in central Norway, near the coast. It is one of the greatest farming districts in the country. Hedmark lies in south-east Norway, about 300 miles from the west coast.

The individual samples were taken from batches of about 22,000 l. Each sample contained 250 gm. of dried milk, the same as the standard sources used for calibration. The canning was also identical. Measurements of samples were carried out over periods of 4 hr. or more. Background and calibration runs were made from time to time. No significant variations in the number of counts stored in the cæsium-137 and potassium-40 photopeaks, exceeding the statistical errors, were observed. No radioactivity which could be attributed to radio-elements other

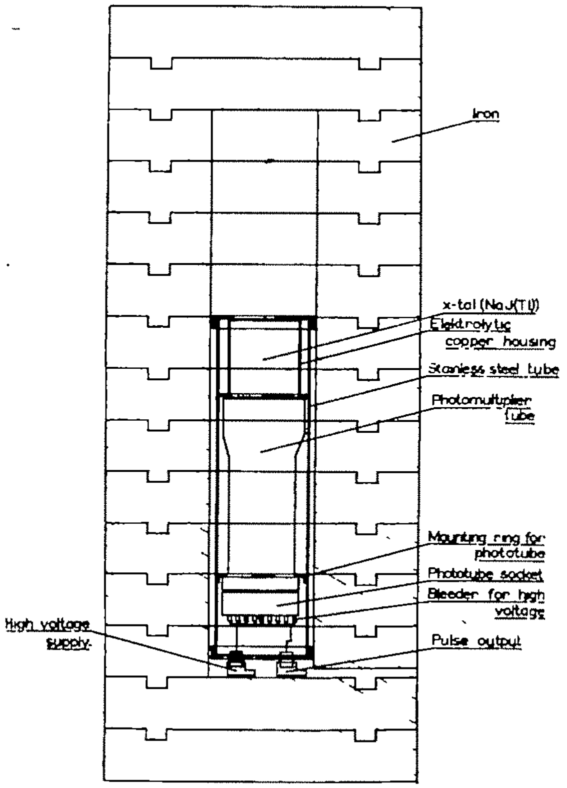

Fig. 1. Scintillation detector and shielding used

than cæsium-137 and potassium-40 was observed in the dry milk measured. In this connexion it must be mentioned that the measurements of the samples from 1958 were all made early in 1959. The other samples were usually measured one month after the date of manufacture.

The results were analysed by counting the observed pulses in the photopeak only, and subtracting the background, correcting for drift of the photopeak region exceeding 0·5 per cent. Because of the scattering of the 1·46 MeV. γ-radiation from potassium-40 and secondarily produced radiation (bremsstrahlung) caused by the β-particles from potassium-40 ($E_\beta = 1 \cdot 4$ MeV.), it was necessary to apply a correction term to the number stored in the cæsium-137 photopeak. This fraction was determined experimentally by observing the extra counts in the cæsium-137-region as a result of an added known amount of potassium-40 mixed into the samples.

With the crystal size and geometry used in the present arrangement, the correction factor has been found to be 22 per cent of the net counts in the potassium-40 photopeak. This value is in close agreement with theoretical calculations based on the resolution obtained for cæsium-137 and potassium-40 (11·0 per cent and 7·0 per cent respectively).

Because of the nature of the radiation process, each measurement carries a statistical error, consisting of the error in the background and sample determination. The results of the measurements are shown in Table 1, together with the experimental errors.

Table 1 shows that the potassium content in the samples amounts to 14–17 gm./kgm. for skimmed dry milk, and 10–12 gm./kgm. for full-cream dried milk. These values are in good agreement with results obtained elsewhere[5,7,8].

The cæsium-137 content during the period January 1958–August 1959 shows the same tendency for both the skimmed and full-cream dried milk from both areas. During the spring of 1958, there is a slow increase in the cæsium-137 content up to June, where an increase of nearly a factor of 2 is recorded. The reason for this sudden jump is primarily in the feeding of the cows with fresh grass. In the autumn, from October 1958, there is a general tendency towards decrease until January 1959, when a value of 310 pc. cæsium-137/kgm. is found in full-cream dried milk from Hedmark, and 650 pc. cæsium-137/kgm. in skimmed milk from Tróndelag. These values are considerably higher than those reported for January 1958. A decrease is further noticed during the spring of 1959, lasting until April. In May the content of cæsium-137 reaches a value of 1,005 pc./kgm. for skimmed milk from Trondelag. This increase continues, and a value of 1915 pc./kgm. is reached in August 1959. This is the highest level found by us in dried milk.

It is of interest to compare the values of the cæsium-137 content in milk, both with the measured

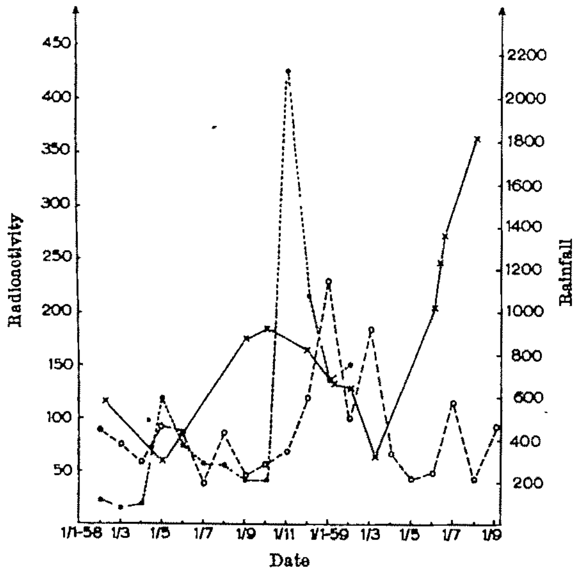

Fig. 2. Total fall-out/month, mm. rainfall/month, and cæsium-137 content (pc./kgm.) in dry milk as a function of time (from Trondelag). ●. . . ●, total fall-out/month (mc./km.²); ○ - - - ○, rainfall/month (mm.); × —— ×, cæsium-137/kgm.

values of the total fall-out[9] and the local rainfall. During the summer of 1957, the total fall-out in Tröndelag (Værnes) remained quite constant at 30–35 mc./km.², increasing to 84 mc./km.² in October. These values must be taken into consideration in predicting the content of cæsium-137 in the milk during the winter and spring of 1958, when the cows were fed on hay collected in the summer and autumn of 1957.

The value of the total fall-out is higher in the spring and summer of 1958 than in the preceeding year, ranging up to 119 mc./km.² in April. Fig. 2 shows the total fall-out, the cæsium-137 content in dry milk and the rainfall as a function of time. The seasonal variations in the cæsium-137 content in milk are easily seen from the curves. There is a remarkable increase during spring and summer, and a decrease in the late autumn and winter. There seems to be a slight tendency toward a correlation between the total fall-out and the measured concentration of cæsium-137, the latter lagging by 4–6 months. This correlation is, however, very doubtful, due to the large amount of short-lived fission products in the fall-out.

It is obvious from Table 1 and the curves that the content of cæsium-137 in milk has increased considerably during the past year and a half. It is of special interest to continue these measurements at the present time, when no test explosions have taken place for about a year, in order to establish the maximum level for cæsium-137 in milk and the time required to reach this point.

We are indebted to the Norske Melkefabrikker for the regular supply of milk samples, to the Norwegian Defence Research Establishment for interest and finally to the Norwegian Cancer Society for financial support.

ALKALINE CONVERSION OF 4-HYDROXYPHENYLPYRUVIC ACID TO 4-HYDROXYBENZALDEHYDE

By Dr. C. H. DOY*

Chemical Microbiology Unit, Department of Bacteriology, University of Melbourne

DURING recent investigations of the biosynthesis of aromatic compounds by *Escherichia coli* and *Aerobacter aerogenes* (to be published) a compound, compound *C*, was detected in experimental samples by the appearance of an absorption maximum at 325–330 mμ, *p*H > 12. Compound *C* was later recognized as 4-hydroxybenzaldehyde, which absorbs as shown in Fig. 1. It was realized that this compound was largely an artefact resulting from the action of alkali on another compound, compound *D*. Compound *D* was then found to be identical with 4-hydroxyphenylpyruvic acid. It is the aim of this communication to bring to notice the alkaline conversion of 4-hydroxyphenylpyruvic acid to 4-hydroxybenzaldehyde.

A sample of 4-acetoxy-α-acetamido-cinnamic acid was prepared by the method of Saul and Trikojus[1] and recrystallized from ethanol (m.p. 228° C., $C_{13}H_{13}NO_5$ requires: C, 59·3; H, 5·0; N, 5·3; O, 30·4 per cent; found: C, 59·3; H, 5·2; N, 5·5; O, 30·4 per cent). This was hydrolysed as required to 4-hydroxyphenylpyruvic acid using Dowex cation exchange resin 50 – × 8 (hydrogen form) as described by Acerbo, Schubert and Nord[2]. The product, m.p. 215–217° C., gave better crystals when recrystallized from 0·1 *M* hydrochloric acid although the m.p. fell to 212–216°, perhaps because of the presence of tautomeric forms. Paper chromatography indicated the presence of a little 4-hydroxybenzaldehyde. This impurity was consistent with the analytical figures for the recrystallized 4-hydroxyphenylpyruvic acid ($C_9H_8O_4$ requires: C, 60·0; H, 4·45; O, 35·5 per cent; found: C, 60·18; H, 4·69; O, 35·0 per cent). The spectrum of a 10^{-3} *M* solution in 0·1 *M* phosphate buffer, *p*H 7·7 (Fig. 2) closely approximated to the spectrum of the keto form of 4-hydroxyphenylpyruvic acid in aqueous solution given by Knox and Pitt[3]. $E_{276\,m\mu} = 2\cdot1 \times 10^3$ was

---

* Present address: Department of Bacteriology and Immunology, Harvard Medical School, Boston, Mass., U.S.A.

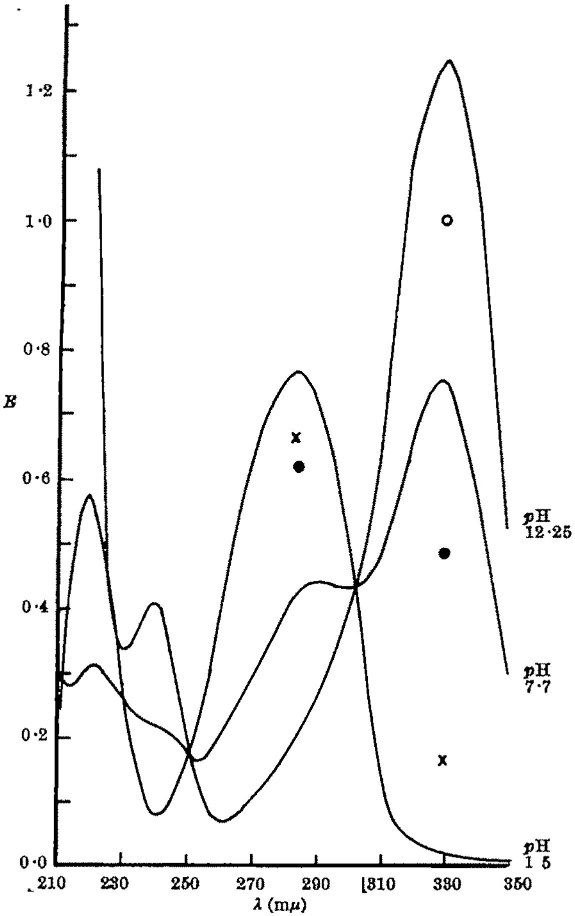

Fig. 1. Ultra-violet absorption of $0\cdot5 \times 10^{-4}$ *M* 4-hydroxybenzaldehyde. Original solution in 0·1 *M* phosphate buffer, *p*H 7·7. Samples were adjusted with 10 *N* sodium hydroxide or 10 *N* hydrochloric acid to the desired *p*H. Absorption at *p*H 12·25 is attributed to 100 per cent phenate ion (constant above approx. *p*H 9) and at *p*H 1·5 to 100 per cent undissociated phenol (constant below approx. *p*H 6·0). ○, *p*H 8·0; ●, *p*H 7·45; ×, *p*H 6·9

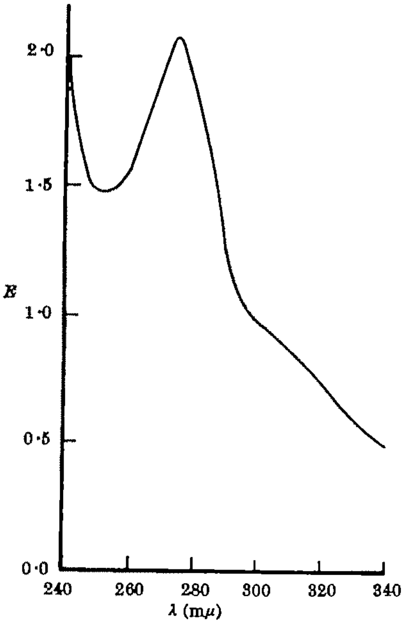

Fig. 2. Ultra-violet absorption of 10^{-3} *M* 4-hydroxyphenylpyruvic acid in 0·1 *M* phosphate buffer, *p*H 7·7

similar to the value $2\cdot27 \times 10^{3}$, calculated from Fig. 2 of these authors. With the exception of the case cited below, further purification by paper chromatography did not affect the changes to be described. Ultra-violet absorption measurements were recorded manually from short to long wavelength using a Unicam *SP* 500 spectrophotometer and 1-cm. silica cells. Because of the rapidity of some of the changes it would be preferable to use an automatic recording instrument if this work was extended.

Fig. 3 shows the irreversible spectral change which occurred when the *p*H was raised to >12. This change was almost instantaneous even at room temperature (20–25°). Subsequent variation of the *p*H produced changes of adsorption characteristic of 4-hydroxybenzaldehyde (cf. Fig. 1) with definite isobestic points at 300 mμ and 250–255 mμ. The absorption maximum at 330 mμ was attributed to the phenate ion and that at 280–285 mμ to the undissociated phenol. The *pK* value for this ionization was calculated from the absorption data as

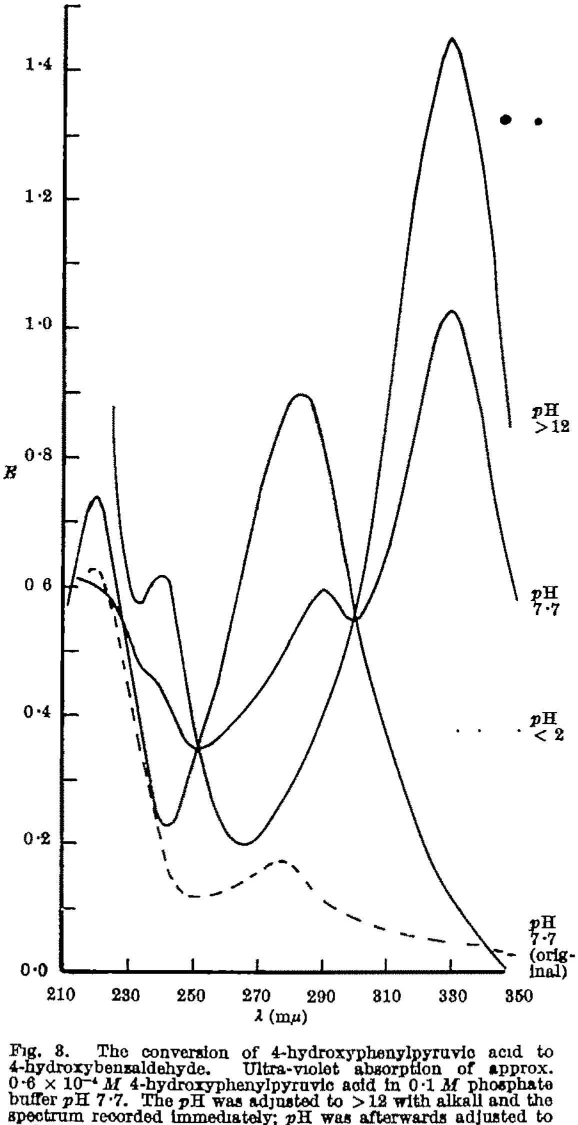

Fig. 3. The conversion of 4-hydroxyphenylpyruvic acid to 4-hydroxybenzaldehyde. Ultra-violet absorption of approx. $0\cdot6 \times 10^{-4}$ *M* 4-hydroxyphenylpyruvic acid in 0·1 *M* phosphate buffer *p*H 7·7. The *p*H was adjusted to >12 with alkali and the spectrum recorded immediately; *p*H was afterwards adjusted to < 2 and then 7·7 (cf. original curve at *p*H 7·7). $E_{\max}$ 240 mμ tends to be lost on storage as found with 4-hydroxybenzaldehyde

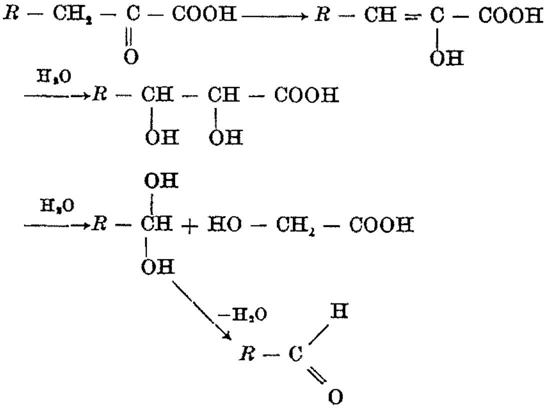
7·68 ± 0·08 which was in agreement with the value 7·66 calculated from the literature[4].

The following mechanism is tentatively proposed for the alkaline conversion of 4-hydroxyphenylpyruvic acid to 4-hydroxybenzaldehyde.



$$R-CH_2-\underset{\underset{O}{\|}}{C}-COOH \longrightarrow R-CH=\underset{\underset{OH}{|}}{C}-COOH$$

$$\xrightarrow{H_2O} R-\underset{\underset{OH}{|}}{CH}-\underset{\underset{OH}{|}}{CH}-COOH$$

$$\xrightarrow{H_2O} R-\overset{\overset{OH}{|}}{\underset{\underset{OH}{|}}{CH}} + HO-CH_2-COOH$$

$$\xrightarrow{-H_2O} R-C\genfrac{}{}{0pt}{}{\diagup H}{\diagdown\!\!\diagdown O}$$

Support for an intermediate chromophorically similar to tyrosine was obtained following paper chromatography of 4-hydroxyphenylpyruvic acid in water/ethylmethylketone/diethylamine (77 : 921 : 2)[5] and elution with phosphate buffer, pH 7·7. This treatment for some unknown reason slowed down the effect of subsequent alkali, and thus allowed the detection of transient maxima at 240 mμ and 290–295 mμ similar to the absorption of tyrosine at $pH > 12$ (Fig. 4).

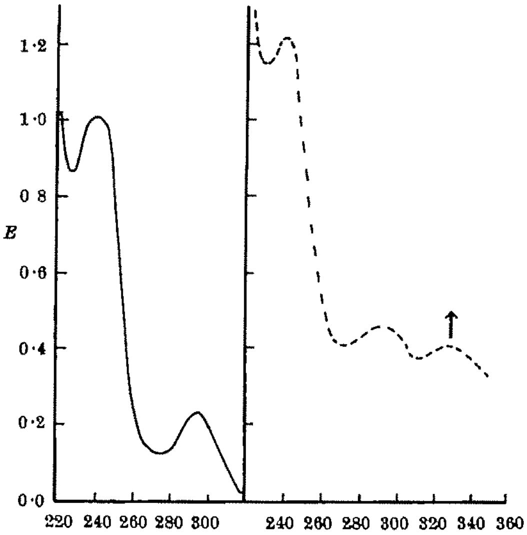


Fig. 4. The absorption at a transient stage in the alkaline conversion of 4-hydroxyphenylpyruvic acid to 4-hydroxybenzaldehyde compared with the spectrum of DL-tyrosine, $pH > 12$ (see text). —, Approx. 10^{-4} *M* DL-tyrosine

It seemed possible that the alkali-induced replacement of a pyruvic acid side-chain by an aldehyde group was a more general reaction. Phenylpyruvic acid eluted from paper chromatograms and treated with alkali ($pH > 12$), first developed an absorption maximum at 320 mμ, which then declined in intensity to an insignificant level. Subsequent adjustment to $pH < 2$ did not result in the changes characteristic of phenylpyruvic acid. In general, the spectral changes seemed consistent with a slow conversion to benzaldehyde, but this was not investigated further. Kaper and Veldstra[6] reported that chromatography of indolepyruvic acid in alkaline solvents gave indolealdehyde as one product of breakdown. It would therefore appear that in the general handling and chromatography of pyruvic acid derivatives of these types, it is as well to avoid high pH particularly since the conversion of 4-hydroxyphenylpyruvic acid to 4-hydroxybenzaldehyde was apparent even at pH10·0.

In lignin chemistry oxidation with nitrobenzene in alkali was introduced[7] as a degradative procedure by which various aromatic aldehydes were liberated, presumably from the lignin. The origin of one of these aldehydes, 4-hydroxybenzaldehyde, gave some concern, and it has been shown[8,9] that protein tyrosine may account for most of this compound released by the nitrobenzene oxidation of buckwheat. Since 4-hydroxyphenylpyruvic acid is considered to be a lignin precursor in grasses[9], the release of 4-hydroxybenzaldehyde from the former using alkali alone may be of particular interest.

This work was supported by a grant from the Australian National Health and Medical Research Council. The analyses were carried out by the Australian Microanalytical Service, Commonwealth Scientific and Industrial Research Organization, Melbourne.

GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY IN RED BLOOD CELLS OF EAST AFRICANS

By Dr. A. C. ALLISON
National Institute for Medical Research, Mill Hill, London, N.W.7

MANY investigations, reviewed by Beutler[1], have shown that about 11 per cent of American Negro males have an intrinsic red blood cell abnormality. A striking feature of the abnormality—and perhaps the primary genetically controlled defect—is low activity of the enzyme glucose-6-phosphate dehydrogenase, which is responsible for the first and rate-controlling step in the hexose monophosphate shunt metabolic pathway in red cells[2]. The defect appears to be inherited as a sex-linked character with full expression in hemizygous males and homozygous females and partial expression in heterozygous

Table 1

Tribe	Locality	Males tested	Enzyme deficiency	Females tested	Enzyme deficiency	Hemizygote = gene frequency
Giriama	Malindi	101	17	65	10	16·8
Bondei	Muheza	121	33	124	24	27·3

females[3]. Persons with the defect are liable to develop severe hæmolysis on exposure to therapeutic doses of the antimalarial 8-aminoquinolines (primaquine, pamaquine, etc.) and certain other drugs, and also on ingestion of broad beans (*Vicia faba*).

The trait is known to be common in many Mediterranean populations, including Sephardic Jews, and also in many South-East Asian populations[1,4]. The only published indications of its presence among continental Africans are isolated reports of hæmolysis induced by pamaquine in a South African, a Nyasaland and an East African Bantu[5,6]. The development of a relatively simple screening test for red cell glucose-6-phosphate dehydrogenase deficiency[4] has made more extensive surveys of the distribution of the trait possible. This report embodies the results of tests on 964 East Africans belonging to 9 different tribes. The test was used as described[4] except that all volumes were reduced to one-half and incubations were carried out in 1-cm. diameter tubes.

The results of the tests are shown in Table 1. Hæmolysates from Western European subjects incubated in the presence of substrate and coenzyme decolorize brilliant cresyl blue in less than 120 min. Hæmolysates from male Africans show a clear bimodal distribution of decoloration times, with the antimode at about 120 min. Spectrophotometric analysis of glucose-6-phosphate dehydrogenase activity[7] in some of the subjects showing decoloration times of longer than 120 min. confirmed that they had significantly lower enzyme activities than normal subjects, and they were therefore classified as hemizygous for the enzyme-deficiency trait. Female Africans show a much less clear distinction between normal and abnormal groups, but those with decoloration times greater than 120 min. were assumed to be heterozygous or homozygous for the enzyme-deficiency trait. Limited family data were consistent with this assumption. The frequency of the abnormal gene, q, equals the frequency of hemizygotes in the male population. The expected frequency of heterozygotes and homozygotes in the female population is $2q(1 - q) + q^2$, and the proportion of females showing detectable enzyme deficiency was 41 per cent of that expected, other heterozygotes presumably falling within the normal range of variability in the tests.

The results summarized in Table 1 show that the trait is common in East Africans. However, the distribution is far from uniform. High frequencies of the trait (15–28 per cent) are found among tribes living near the coast and around Lake Victoria, and low frequencies (1·7–2·9 per cent) in the intermediate highland country. The distribution of the trait approximately parallels that of the sickle-cell trait in the same region[8]. All other populations known to have high frequencies of the enzyme-deficiency trait[4] live in regions where malaria is, or was until recently, endemic. Thus the local distribution of the trait in East Africa and the overall distribution are consistent with the interpretation that subjects with deficient glucose-6-phosphate-dehydrogenase activities in red cells are at a selective advantage in malarious environments. There are, in fact, metabolic reasons why malaria parasites might not multiply as well in enzyme-deficient cells as in normal red cells[4]. Recently, evidence has been obtained[9] that young malaria-susceptible East African children of both sexes from a region where *P. falciparum* is holoendemic show lower parasite-counts when enzyme deficient than when red cell enzyme activities are normal.

These results suggest that the trait may be maintained as a sex-linked polymorphism by a balance of selective forces. The hemizygote, and to some extent also the abnormal homozygote and heterozygote, are favoured through protection against malaria, and possibly in other ways. On the other hand, the hemizygote, and perhaps also the abnormal homozygote and in exceptional circumstances the heterozygote, may be at a disadvantage owing to their susceptibility to hæmolysis. The broad bean is not normally eaten by East Africans, and why persons with enzyme deficiency are at a disadvantage there is unknown. If there were no disadvantage, the gene might be expected to have become more common, instead of remaining at the same order of frequency among tribes supposed to have different ethnic origins (for example, the Nilo-Hamitic Luo and the Eastern Bantu Bondei). There is disagreement among theoretical geneticists whether a stable polymorphism at a sex-linked locus can be maintained by advantage of the hemizygote alone or whether the heterozygote must be favoured[10]. The finding that enzyme-deficient female as well as male children have lower malaria parasite counts than children with normal red cell enzymes means that both processes could apply in this particular case.

This investigation was supported by a grant from the Colonial Development and Welfare Fund received at the instance of the Colonial Medical Research Committee. I am indebted for hospitality and help to many East African workers, in particulars Drs. D. B. Wilson and D. F. Clyde, Amani; H. Foy, Nairobi and S. Buck, Kampala.

A NEW COPPER PROTEIN FROM *CHLORELLA ELLIPSOIDEA*

By Dr. SAKAE KATOH

Department of Biophysics and Biochemistry, Faculty of Science, University of Tokyo

THE significance of copper in the metabolism of *Chlorella* was first described in 1939 by Green, McCarthy and King[1], who investigated the inhibitory effect of copper-chelating agents on respiration and photosynthesis in *Chlorella pyrenoidosa*. Their findings, that carbon dioxide uptake by *Chlorella* was markedly inhibited in the presence of copper-specific inhibitors in concentrations which were apparently without effect on the respiratory activity of the organism, and readily reversed on the removal of the poison by dialysing the cell suspension against water, indicated the participation of copper in the photosynthesis of *Chlorella*. However, there has been no positive effort to elucidate the function and properties of the copper compound in question. In a series of studies carried out in this laboratory to investigate the oxidation-reduction system in algae, a copper protein complex possessing the capacity to undergo a reversible oxidation-reduction reaction was isolated from *Chlorella ellipsoidea*. A similar substance was also found in the chloroplasts of higher plants. This article will briefly describe the isolation and purification as well as several properties of the copper protein obtained from *Chlorella ellipsoidea*.

The copper protein was readily extracted by disrupting the algal cells for 30 min. in a sonic oscillator (20 kc./s.) with the addition of about a half weight of alumina, or by soaking the lyophilized cells or acetone powder of *Chlorella* in a sufficient amount of dilute phosphate buffer of neutral *p*H. The typical procedure for extraction and purification of the substance is as follows: 1 kgm. of lyophilysed cells of *Chlorella ellipsoidea* was suspended in 8·0 l. of 0·01 *M* phosphate buffer (*p*H 7·0), and left at 10° C. for 16 hr. with several stirrings. The algal cells were removed by centrifugation at 3,000*g* for 20 min., and 300 gm. of ammonium sulphate was added with stirring to 1·0 l. of the supernatant. The precipitate formed was removed by centrifugation at 3,000*g* for 30 min. and the supernatant was saturated with ammonium sulphate and left at room temperature for 1 hr. The precipitate formed was collected by centrifugation, dissolved in a small amount of water and dialysed for 24 hr. against 0·02 *M* phosphate buffer, *p*H 7·0. Further purification of the substance was carried out by column chromatography, using diethylaminoethyl-cellulose as adsorbent. The substance dialysed was charged on a column (3 cm. in diameter and 10 cm. in height) packed with the adsorbent buffered with 0·02 *M* phosphate buffer, *p*H 7·0. The charged column was thoroughly washed with a sufficient amount of 0·05 *M* phosphate buffer *p*H 7·0, and the substance was eluted with 0·2 *M* phosphate buffer, *p*H 7·0.

The eluate thus obtained showed a bright yellow colour and, on addition of ferricyanide, its colour changed to green, indicating the oxidation of the copper protein which had been in the reduced form. The values for the degree of purity of the eluate as the ratio of extinction at 278 mμ (maximum of protein peak) to that at 597 mμ (maximum of peak in visible region, see below), was found to be 4·8. The oxidized substance, if not so highly purified, was generally found to undergo a gradual auto-reduction without any addition of reducing agents, and even after thorough dialysis against water. The substance was therefore subjected to subsequent chromatography in the reduced form to prevent the broadening of the elution pattern. The copper protein, dialysed and reduced with ascorbic acid, was again charged on a column of diethylaminoethyl-cellulose equilibrated with 0·02 *M* phosphate buffer, *p*H 7·0 (2 × 20 cm.). The column was washed with 0·05 *M* and 0·1 *M* of phosphate buffer (*p*H 7·0) and the substance was then eluted with 0·2 *M* of phosphate buffer, *p*H 7·0. This procedure was repeated until no yellow colour was observed in the eluate. The water-clear solution thus obtained had a purity index (see above) of 2·6 and showed the deep-blue colour of oxidized copper protein on the addition of ferricyanide. It was found that the oxidized substance, in this stage of purification, was no longer auto-reducible. The last manipulation of column chromatography was therefore carried out with the oxidized substance. In this case, the charged column was washed with 0·03 *M* phosphate buffer, *p*H 7·0, and the substance was eluted with 0·1 *M* of phosphate buffer, *p*H 7·0. The value finally obtained for the purity index was 1·63.

Fig. 1 shows the absorption spectra of the oxidized and reduced form of the substance. In the oxidized form, a sharp absorption peak due to the protein has a maximum at 278 mμ and a slight shoulder at 284 mμ. In the visible region, there is a broad absorption peak ranging from 500 mμ to 700 mμ and possessing a maximum at 597 mμ. In the reduced form, no absorption was observed in this region. The blue colour of the oxidized substance was found to disappear on addition of sodium diethyl-dithiocarbamate or on dialysing against salicylaldoxime or cyanide solution; this reappeared, although not completely, on dialysis for 24 hr. against a copper sulphate

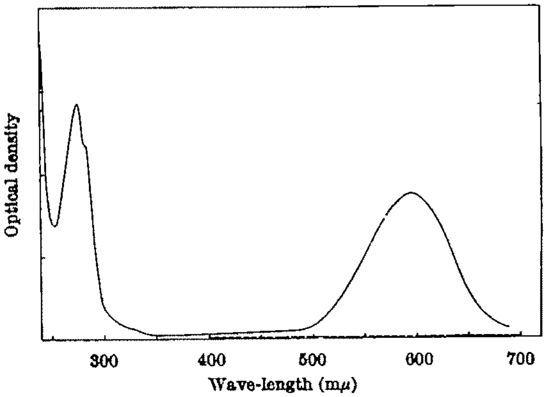

Fig. 1. Absorption spectra of copper protein from *Chlorella ellipsoidea*. Solid line, oxidized form; broken line, reduced form (reduced with ascorbic acid)

solution of 10^{-3} *M*. A spectrophotometric experiment revealed that the blue colour which reappeared was due to an absorption peak identical with that of the untreated preparation. It is inferred from these findings that the characteristic peak in the visible region is due to copper in the form of a complex with protein.

The oxidation-reduction potential of the substance is determined, using a ferri- and ferro-cyanide mixture as oxidation-reduction buffer. In Fig. 2, the values for log (ferrocyanide/ferricyanide) are plotted against those for log (reduced copper protein/oxidized copper protein). The slope of the curve indicates a one-electron change in the oxidation and reduction of the copper protein. From these results, the normal potential of the copper protein is calculated to be 390 mV. at 20° C. and *p*H 7·0.

The reduced form of the purified copper protein was found to be non-auto-oxidizable. The oxidized substance was reduced with ascorbic acid, hydroquinone and other ordinary reducing agents. It was found that the copper protein was instantaneously reduced by reduced mammalian cytochrome *c* and *Chlorella ellipsoidea* cytochrome 550, which was isolated and purified from *Chlorella ellipsoidea* (details will be published elsewhere). Since cytochrome *f* of *Chlorella* has not been successfully isolated, the reactivity of the copper protein was tested also, with positive results, with another algal cytochrome of high oxidation-reduction potential, *Porphyra tenera* cytochrome 553[2].

A rapid reduction of the oxidized copper protein with reduced pyridine nucleotide as electron-donor was found to be catalysed by the presence of the cell-free extract of *Chlorella*. This reductase was partially purified by fractional precipitation with ammonium sulphate and column chromatography, using diethylaminoethyl-cellulose as adsorbent. (The preparation thus obtained showed a yellow colour, which disappeared on reduction with sodium hydrosulphite. The absorption spectrum of this substance in the oxidized form showed three peaks with absorption maxima at 275, 380 and 465 mμ suggesting the flavoprotein nature of the enzyme.) As will be seen in Fig. 3, this enzyme catalyses the reduction of the oxidized copper protein with reduced pyridine nucleotide as electron donor. The rate of this reaction was markedly faster with reduced triphosphopyridine nucleotide than with reduced diphosphopyridine nucleotide. It was also found that this preparation had the capacity to catalyse the reduction of oxidized mammalian cytochrome *c* with reduced triphosphopyridine nucleotide (Fig. 3). It is impossible to compare the activity of this enzyme toward the copper protein with that toward cytochrome until the molar extinction coefficient of the former is estimated.

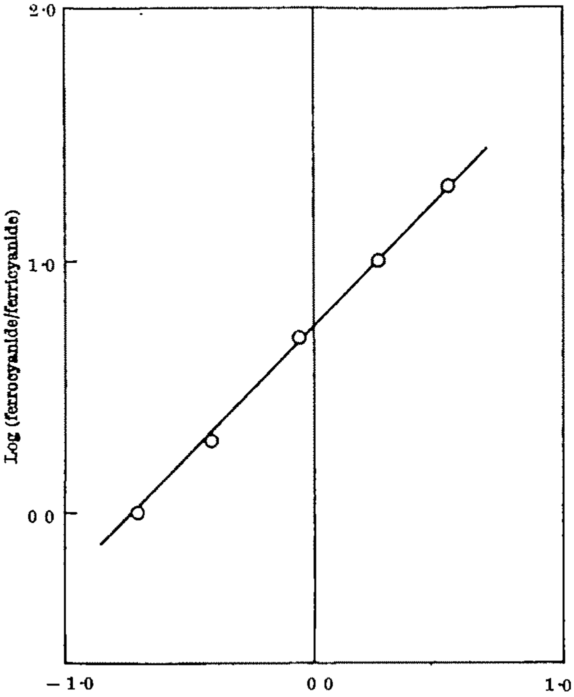

Fig. 2. Oxidation-reduction potential of copper protein from *Chlorella ellipsoidea*. The points refer to the degree of oxidation of copper protein of *Chlorella ellipsoidea* in the presence of varied ratios of ferrocyanide versus ferricyanide in the reaction mixture

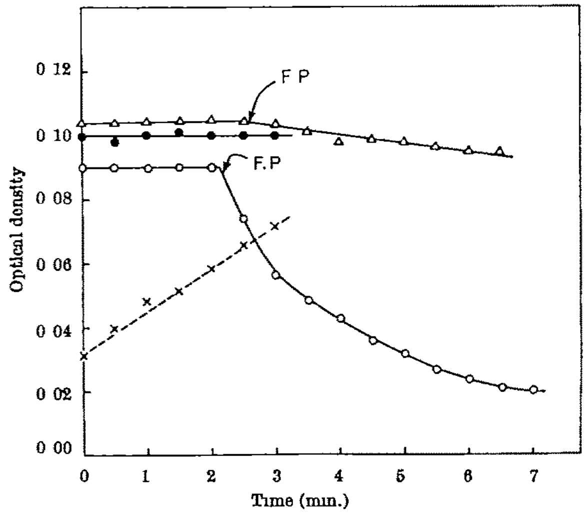

Fig. 3. Reduction of copper protein (and mammalian cytochrome *c*) with reduced pyridine nucleotide as catalysed by *Chlorella* flavoprotein. Reaction mixture, 1·0 ml. of 0·5 *M* phosphate buffer (*p*H 7·0), 0·5 ml. copper protein or horse heart muscle cytochrome *c*, 0·1 ml. reduced pyridine nucleotide, 0·05 ml. flavoprotein and deionized water in 3·0 ml. The reaction was followed spectrophotometrically at 596 mμ and 550 mμ for the reduction of copper protein and cytochrome *c*, respectively. ○, △, reduction of copper protein with reduced triphosphopyridine nucleotide and reduced diphosphopyridine nucleotide, respectively. Flavoprotein was added at the time marked *F.P.* ●, absorption in the presence of copper protein and flavoprotein alone (that is, without addition of reduced pyridine nucleotide); ×, reduction of cytochrome *c* with reduced triphosphopyridine nucleotide. Flavoprotein was added as catalyst at time zero

A substance with similar spectrophotometric and electro-chemical properties has been extracted from chloroplasts of spinach by K. Takamatsu (personal communication) in this laboratory. It has also been discovered by me in the chloroplasts of *Chrysanthemum coronarium*. The wide distribution of this substance in various photosynthetic organisms suggests that it is playing some part in the photosynthesis of these organisms. Further investigations to elucidate the physiological function of this substance are in progress.

I wish to thank Prof. A. Takamiya for his valuable advice and encouragement in this work. Lyophilized algal cells were kindly provided from the Tokugawa Biological Institute.

Gravitational Waves in General Relativity

THE emission of gravitational waves from a finite isolated axially symmetrical material system in otherwise empty space has been investigated by consideration of the metric :

$$ds^2 = \left(\frac{V}{r}e^{2\beta} - r^2e^{2\gamma}U^2\right)du^2 + 2e^{2\beta}du\,dr +$$

$$2r^2Ue^{2\gamma}du\,d\theta - r^2\left(e^{2\gamma}d\theta^2 + \sin^2\theta\, e^{-2\gamma}d\varphi^2\right)$$

Einstein vacuum field equations have been solved by an expansion in negative powers of r which represents radial distance in a well-defined sense. In this expansion it has been assumed that only outgoing waves are present. The expression :

$$\tfrac{1}{4}\lim_{r\to\infty}\int_0^\pi (r - V)\sin\theta d\theta$$

represents mass in the static case, and forms a suitable generalization of this static concept to the dynamical case.

The following results have been found :

(1) If a system is static before some instant, then undergoes motion, and eventually again returns to a static state, then its mass in the final state is less than its mass in the initial state.

(2) There exists a class of possible motions of the source in which the curvature tensor (measured by its physical components) falls off like r^{-3}. In this case no radiation is sent out and no loss of mass occurs. The existence of such a class of motions is related to Infeld's[1] result that a set of freely moving particles does not radiate. This case differs from the stationary one by, among other characteristics, lim $(r - V)$ being a function of θ though not of u.

(3) There exists a class of motions of the source in which the curvature tensor falls off like r^{-2}. In this case the power received by a set of small receivers covering a large sphere surrounding the source tends to zero as the radius of the sphere tends to infinity, since small receivers absorb energy at a rate proportional to the square of the curvature tensor. Nevertheless the source loses mass, because at any distance from the source a suitably constructed large receiver could absorb a finite amount of energy.

(4) For general motions the curvature tensor falls off like r^{-1}, but, because of (2), there is no close relation between the mass loss of the source and the energy that could be absorbed by distant small receivers. This point underlines the non-localizable nature of gravitational energy.

I am much indebted to Dr. F. A. E. Pirani for innumerable discussions that have done much to improve my understanding of the problem.

Full details of the work (carried on partly in collaboration with Dr. M. G. J. van der Berg, Department of Applied Mathematics, University of Liverpool) will be published elsewhere.

PHYSICS

Time-Dependent Tensile Strength of Solids

DURING the course of studying the strain-rate effects of a number of irradiated and non-irradiated polymeric solids as well as some metallic solids (refs. 1 and 2 and unpublished results) a common relationship between stress and strain-rate has been observed. For any given value of strain the stress obtained at different rates of straining is linearly related with the logarithm of the strain-rate. Mathematically, if ε is the total given strain at any given temperature T, then the stress σ is related with the strain-rate $\dot\varepsilon$ in the following manner :

$$\dot\varepsilon = \dot\varepsilon_0 e^{\frac{\sigma - \sigma_0}{m}}\Bigg|_{\varepsilon} \qquad (1)$$

where $\dot\varepsilon_0$ and σ_0 are constants independent of the strain ε, and m, which is also independent of the strain, is the slope of the straight line when the log of strain-rate is plotted against the stress. Or in another form, when the rate of straining is constant :

$$t = \frac{\varepsilon}{\varepsilon_0} e^{\frac{\sigma_0 - \sigma}{m}}\Bigg|_{\dot\varepsilon} \qquad (2)$$

Depending upon the value of ε, which is a measure of molecular configuration of the solid in terms of deformation[3], the time-dependent strength can be evaluated.

As one special case, if we let :

$$\dot\varepsilon = \dot\varepsilon_b = \frac{\varepsilon_b}{t_b}$$

then from (1) :

$$t_b = \frac{\varepsilon_b}{\dot\varepsilon_0} e^{\frac{\sigma_0 - \sigma_b}{m}} \qquad (3)$$

where t_b is the time to fracture, ε_b is the fracture strain and σ_b the stress maintained until fracture occurs. This agrees well with the current theoretical and experimental developments of the subject[4-8].

On the basis of considering the oscillation and breaking of atomic bonds, the time-dependent strength properties of solids has been reported and may be expressed as follows[4] :

$$t_b = \frac{1}{\omega} e^{\frac{E - 2\delta\frac{\delta}{n}\sigma_b}{kT}} \qquad (4)$$

where t_b is the time taken for the sample to break under the tensile stress σ_b, ω corresponds to some bond oscillation frequency, n is the number of bonds per unit area the normal of which is in parallel to these bonds, E is the bond energy, 2δ is approximately the distance the bond will stretch before

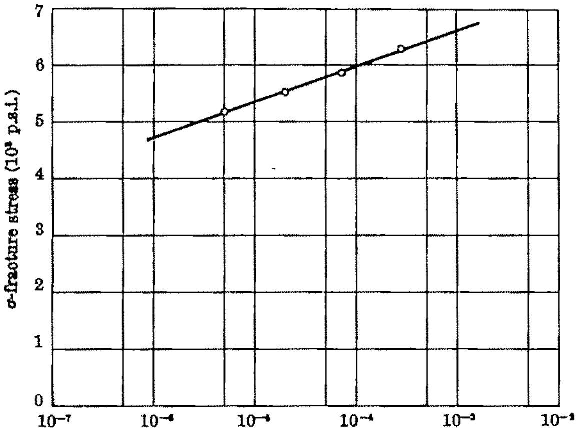

Fig. 1. Effect of strain-rate on breaking stress of polystyrene solid

breaking, k is the Boltzmann constant, and T is the absolute temperature.

According to another theoretical analysis based on the theory of absolute reaction-rates for simple tension[5], the time taken to fracture is related to a constant fracture stress σ_b of a solid body in the following manner:

$$\log t_b = A - B\,\sigma_b \tag{5}$$

where t_b is the time to fracture and A and B are constants.

Experimentally similar results have been obtained[7,8] for various solids. Hsiao and Sauer[7] have reported this linear relationship between breaking stress and logarithm of time for solid polystyrene at room temperature. Zhurkov and his colleagues[8] have made a systematic study of not only time- but also temperature-dependent fracture phenomena for a large number of various solids. The time t_b taken for a solid to fracture under a constant stress σ_b was found to obey a general law that:

$$t_b = t_0 e^{\frac{U_0 - \gamma\sigma_b}{kT}} \tag{6}$$

where t_0, U_0 and γ are constants which define the strength properties of the solid. It is interesting that the quantity U_0 was found to coincide in magnitude with the binding energy of atoms in the crystal lattice of metals and alloys. The quantity t_0 was found to be constant for all the metals investigated and of the same order of magnitude as the period of vibration of atoms in the crystal lattice. A very close resemblance between (6) and (3) is quite evident.

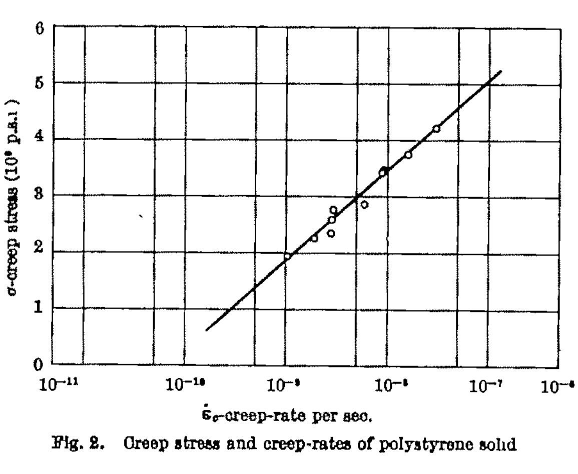

Fig. 2. Creep stress and creep-rates of polystyrene solid

As another special case in the creep process the total strain-rate is equal to the creep-rate, that is, $\dot{\varepsilon} = \dot{\varepsilon}_c$ and $\dot{\varepsilon}_0 = \dot{\varepsilon}_{0c}$, where ε_c and ε_{0c} are creep strains. Using these relations, if σ_c is the creep stress, then (1) can be reduced to the following form:

$$\dot{\varepsilon}_c = \dot{\varepsilon}_{0c}\, e^{-\frac{\sigma_0 - \sigma_c}{m}} \tag{7}$$

indicating that the plots of $\log t_b - \sigma_b$ from (3) and $\log \dot{\varepsilon}_c - \sigma_c$ from (7) have equal but opposite slopes. This is well illustrated by Zhurkov's excellent experimental work for metals and alloys[9].

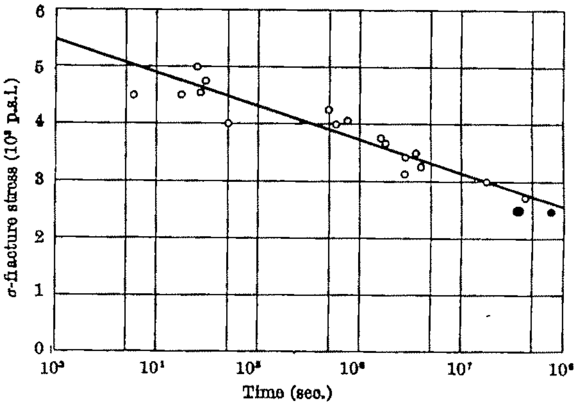

Fig. 3. Effect of time on fracture stress of polystyrene solid

Quite recently, Zhurkov and Sanfirova[9] have obtained the relation between the strength and the constant creep-rate of metals and alloys. They found that:

$$\dot{\varepsilon}_c = \varepsilon_{0c}\, e^{-\frac{Q_0 - \gamma_1\sigma}{kT}} \tag{8}$$

where $\dot{\varepsilon}_c$ is the creep-rate and $\dot{\varepsilon}_{0c}$, Q_0 and γ_1 are constants. They further determined that $Q_0 = U_0$ and $\gamma_1 = \gamma$ for a number of metallic solids. They also claimed that U_0 is dependent on stress, in contrast with the result by Dorn and his co-workers[10] that the activation energy is independent of the stress. But Basinski[11] and others have found that the activation energy is stress-dependent. According to the present analysis the activation energy is not only dependent on stress but also on strain.

However, in order to consider the possibilities of having different mechanisms of creep deformation for different types of solids, it is desirable to use m as the variable parameter.

For metals and alloys, m has one value which reflects one type of mechanism of deformation associated with various dislocations. But for polymer solids m has another value which reflects a different type of deformation mechanism. To give an actual example, consider the time-dependent mechanical properties of solid polystyrene. The effect of log of strain-rate on the fracture stress is shown in Fig. 1. The plot of the log of creep-rate against the creep stress is given in Fig. 2. The slopes of the two curves are evidently not the same. Comparing with the curve plotted in Fig. 3, the log of time against fracture stress, it is seen that the slope of this curve is equal but opposite to that of the curve in Fig. 1.

In conclusion, it seems reasonably safe to consider that in describing the time-dependent tensile strength properties of a large number of solids there exists a basic linear law between the logarithm of strain-rate $\dot{\varepsilon}$ and the applied tensile stress σ :

$$\dot{\varepsilon} = \dot{\varepsilon}_0 e^{\frac{\sigma - \sigma_0}{m}} \Big|_{\varepsilon}$$

where $\dot{\varepsilon}_0$ and σ_0 are constants and m is a material constant proportional to the absolute temperature T.

Size Distribution of Tobacco Smoke Droplets by a Replica Method

HITHERTO it appears that when size distributions of tobacco smoke droplets have been made by light or electron microscopy, the droplets have been caught on glass surfaces or one of the usual kinds of specimen support film, and upon deposition they have spread on the sampling surface (Fig. 1*a* and *c*). As a result, published size distributions obtained by these methods have been of the spread diameter of the droplets instead of their true diameter as they existed in the smoke at the time of sampling.

A replica method for determining the size distribution of non-volatile droplets by electron microscopy[1] makes it possible to relate the diameters of lens impressions, formed by spread-out droplets sampled on a wet gelatine film, to the diameter of the droplets themselves. This method has now been applied successfully to the determination of the size distribution of tobacco smoke droplets.

Comparative size distributions of cigarette smoke droplets have been made on samples obtained simultaneously on collodion support films by means of the thermal precipitator (Fig. 1*a*) and an electrostatic precipitator, and on wet gelatine film by means of the electrostatic precipitator followed by the replica method (Fig. 1*b*). The electrostatic precipitator was of the parallel-plate type with an electrode separation of 1 cm. and employing a potential difference of 5 kV. Droplets from the smoke of an artificially smoked cigarette without filter tip and a normally smoked cigarette also without filter tip have been examined. The artificial smoking was carried out by inserting the lighted cigarette in the inlet of a 1-litre glass sampling cylinder and drawing smoke through by means of a hand sampling pump at the rate of 35 ml./2 sec. To obtain the normally smoked cigarette cloud, the smoker drew smoke into the mouth and filled the sampling cylinder by gently blowing the smoke into it. In both cases the smoke was approximately 10 sec. old when sampling was commenced, and the concentration was such that a satisfactory thermal precipitator sample was obtained in 2 sec. and the electrostatic precipitator samples in 10 sec.

The size distribution of droplets in artificially produced cigarette smoke obtained by the three methods of sampling is shown in Fig. 2. Diameters shown are for the spread droplets and the number median diameters are 2·1μ for the thermal precipitator sample, 2·4μ for the electrostatic precipitator sample on collodion film and 0·38μ for the gelatine replica. Only in the case of the replica sample can these values be related to actual droplet diameters. The spread factor[1] (droplet diameter/replica diameter) for tobacco smoke droplets on gelatine was found to be 0·435, so that the median droplet diameter was actually 0·16μ and the maximum droplet diameter 0·54μ. For droplets in the smoke from a normally smoked cigarette the median values were 1·05μ for the thermal precipitator sample, 1·3μ for the electro-

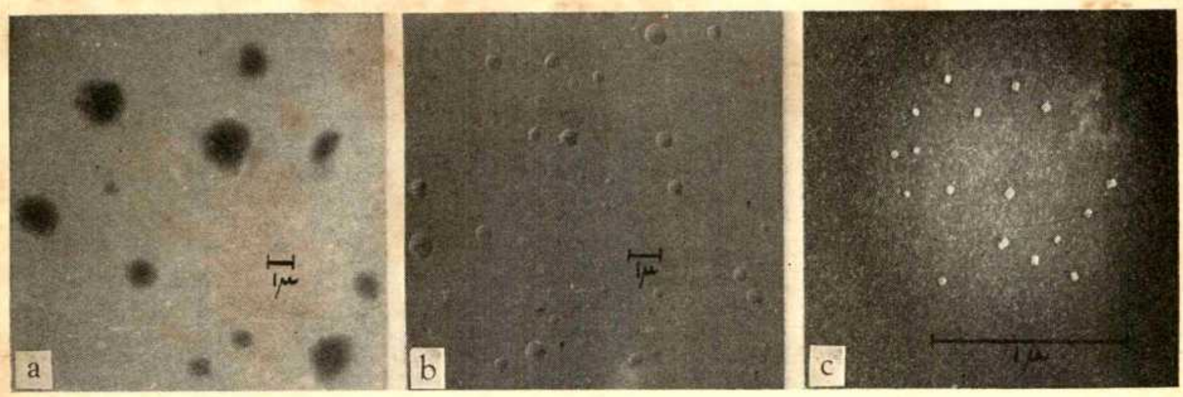

Fig. 1. Electron micrographs of tobacco smoke droplets: (*a*) spread droplets on collodion; (*b*) carbon replica of lens impressions formed by droplets sampled on wet gelatine film; (*c*) spread droplet containing crystals

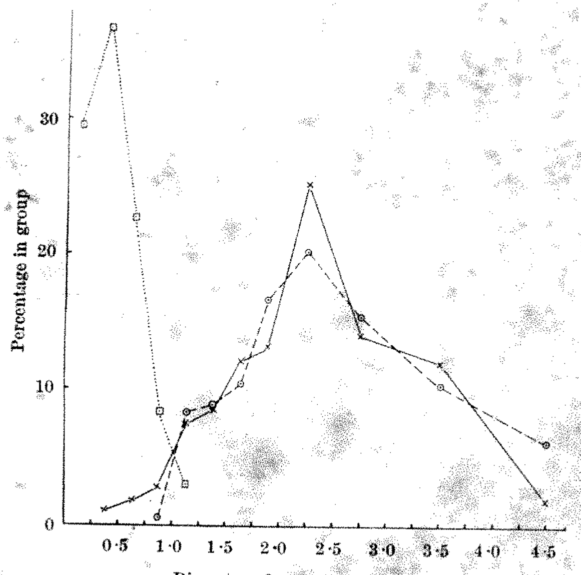

Fig. 2. Size distribution of spread droplets in smoke from an artificially smoked cigarette without filter tip. ×—×, Thermal precipitator and collodion film; ○ – – – ○, electrostatic precipitator and collodion film; □ · · · □, electrostatic precipitator and gelatine film (replica method)

static precipitator sample on collodion film and 0·46μ for the gelatine replica with a true droplet median diameter of 0·2μ.

It is interesting to compare these values with those obtained by other workers. Langer and Fisher[2], sampling on glass and sizing by dark-field microscopy, obtained values for the diameters of 0·6μ (median) and 1·6μ (maximum). For a smoke of similar age, Harris and Kay[3], sampling on 'Formvar' film and sizing by electron microscopy, appear to have obtained a maximum droplet diameter of approximately 5μ, which is the largest size for samples taken on collodion in the present investigation. DallaValle[4], by means of electrostatic separation studies, found a size range of 0·1–0·25μ, and Sinclair[5], using a light-scattering method, a size range up to 0·5μ diameter. It is evident that spreading of the droplets always occurs when they are deposited upon a sampling surface and, unless the spread diameter can be related to the original droplet diameter, size distributions obtained by measuring the diameters of deposited droplets differ considerably from those of the droplets as they exist in the aerosol.

Although the replica method[1] was developed chiefly for electron microscopy, it can conveniently be used for light microscopy; for the examination of tobacco smoke droplets, it virtually increases the resolving power by a factor of 2·3.

The samples taken on collodion film were re-photographed at a higher magnification (×10,000) and crystalline inclusions were observed in many of the spread droplets (Fig. 1c). It is not known whether these crystals (mostly in the size range 0·02–0·04μ) existed in the droplet phase or whether they were the result of some constituent crystallizing out under vacuum in the electron microscope. Kahler and Lloyd[6] found spherical particles of approximately the same size range in cigarette and cigar smoke, and it is possible that the physical form of included particles is some characteristic of the brand of tobacco from which the smoke has been formed.

This application of the replica method was suggested by Mr. H. L. Green, and helpful discussion with him is gratefully acknowledged.

Helium–Butane Gas Mixtures as Fillings for Geiger-Müller Tubes

GAS-FLOW counters are finding an increasing use, especially in automatic methods of counting carbon-14 and tritium in sample-changing devices, and in chromatogram scanners. We have investigated the performance of various mixtures of counting gases in order to determine the factors affecting the choice of an optimum mixture. The gases investigated consisted of helium containing 1·0–2·5 per cent of butane; helium bubbled through ethanol at 0° C. (containing about 1·6 per cent ethanol vapour); and, as standards of reference, 'Tracerlab *G*–1 Geiger Gas' (composition, according to manufacturers, principally helium, *iso*butane, and butadiene, in undisclosed proportions) and 'Nuclear-Chicago *Q*–Gas' (containing nominally 98·7 per cent helium + 1·3 per cent butane).

Curves of counts per minute against voltage (in 50-V. intervals) were recorded to show the usual plateau for each gas in two very different types of gas-flow counter, as described below. Two carbon-14 standard planchettes were used, one for each type of counter. The curves were analysed to give (*a*) the plateau length; (*b*) the operating voltage, taken as one-third of the plateau length above the lower limit of the plateau; (*c*) the slope of the plateau at the operating voltage; and (*d*) the counts per min. of the standard planchette at the operating voltage.

Counter 1 was a Scott-type end-window gas-flow counter[1] used for exploring two-dimensional paper chromatograms and for planchette counting. The end window consisted of I.C.I. 'Melinex 0' (25 gauge), a polyethylene terephthalate film of thickness 0·00625 mm. (0·86 mgm. per cm.^{2}). The diameter of the window and of the cylindrical counting volume was 5·6 cm. The anode was an axial tungsten wire of 0·13 mm. diameter and 1·5 cm. length, supported from the top of the counter tube on a thin brass pillar, and terminating in a glass bead placed about 0·3 cm. behind the window. The carbon-14 planchette was 2·4 cm. in diameter. The counter was used with a 'Nuclear-Chicago Ultrascaler 1924', with the input sensitivity set at 60 mV. This input sensitivity was chosen after a series of 15 runs at different sensitivities between 1 and 800 mV., and has been extensively used in routine operation. Measurements were made at three different gas-flow rates for each gas mixture: 127, 287, and 613 ml. per min., corresponding to a positive pressure inside the counter of 1·2, 2·4, and 4·8 cm. of ethanol, respectively. 1-min. counts were taken.

Counter 2 was a standard 'Nuclear-Chicago *D*–47' counter mounted on a '*C*–110*B*' sample changer, and

Table 1. SUMMARY OF RESULTS IN SCOTT COUNTING TUBE

Gas mixture	Plateau length (V.)	Operating voltage (1/3 from bottom of plateau)	Counts/min. of standard carbon-14 planchette at operating voltage	Plateau slope at operating voltage (per cent/100 V.)
He + 1·0 per cent butane	350	1,600	15,300	4·0
He + 1·1 per cent butane	650	1,825	14,750	3·7
He + 1·5 per cent butane	700	1,900	14,600	1·7
He + 2·0 per cent butane	750	2,100	14,500	0·7
He + 2·5 per cent butane	700	2,200	14,450	0·3
He + ethanol	500	2,050	14,600	2·8
'Nuclear-Chicago *Q*-Gas'	750	2,050	14,350	1·0
'Tracerlab *G*-1 Geiger Gas'	300	1,650	14,400	1·4

connected to the 'Ultrascaler 192*A*'. The tube was used without a window, and the carbon-14 sample occupied an area 1·5 cm. in diameter on a metal planchette. The counting volume was approximately trochoidal in section, with a base diameter of 3·6 cm. The anode was of 0·05-mm. diameter tungsten wire in the form of a horizontal loop 1·5 cm. in diameter placed centrally, and about 1·3 cm. above the planchette. The operating conditions were those recommended by the manufacturers: gas-flow rate 50 ml. per min. after a preliminary flushing period at 200 ml. per min., and the scaler input sensitivity at 250 mV. The counts were each of 3-min. duration.

Tables 1 and 2 give the summarized results from each counter. Of the three flow-rates used in the Scott counter, the lowest was insufficient to sweep out the decomposition products of the discharges, so that the plateau was short and breakdown occurred at relatively low voltages. Increasing the flow-rate gave longer and flatter plateaux, but the difference between the two higher rates of gas flow was not sufficiently great to justify the highest consumption of gas. The results are therefore given for the medium flow-rate of 287 ml. per min. Tables 1 and 2 agree in the comparison of the mixtures investigated with the commercially available gases. Helium + 1·1 per cent butane, and helium + 1·5 per cent butane possessed characteristics closely resembling those of 'Tracerlab *G*-1 Geiger Gas' (except that the 'Tracerlab Gas' showed a smaller plateau slope); the 'Nuclear-Chicago *Q*-Gas' characteristics were in all respects between those of helium + 1·5 per cent butane and helium + 2·0 per cent butane, although the manufacturers stated that this gas consisted of helium + 1·3 per cent butane. The helium + ethanol mixture operated at a relatively high voltage, as did helium + 2·0 per cent butane, but the ethanol plateau was much shorter and steeper (Table 1).

Table 2. SUMMARY OF RESULTS IN *D*-47 GAS-FLOW COUNTER

Gas mixture	Plateau length (V.)	Operating voltage (1/3 from bottom of plateau)	Counts/min. of standard carbon-14 planchette at operating voltage	Plateau slope at operating voltage (per cent/100 V.)
He + 1·0 per cent butane	150	1,000	1,920	4·0
He + 1·1 per cent butane	300	1,250	1,910	4·2
He + 1·5 per cent butane	350	1,300	1,885	3·3
He + 2·0 per cent butane	350	1,500	1,890	2·0
He + 2·5 per cent butane	350	1,550	1,920	1·3
'Nuclear-Chicago *Q*-Gas'	400	1,400	1,900	2·0
'Tracerlab *G*-1 Geiger Gas'	350	1,250	1,900	1·1

These results show that certain helium–butane mixtures from the range investigated are entirely suitable as counting gases. The practical choice is between the 1·5 per cent and the 2·0 per cent proportion of butane. The higher proportion gave a considerably flatter plateau, but also a rather higher operating voltage. Even with a counter tube as large as the Scott-type counter, the helium + 1·5 per cent butane mixture required an operating voltage of less than 2 kV., which is within the range of most commercial high-voltage supplies fitted to scalers. As most counter tubes are smaller than the Scott type, the operating voltage would be well below 2 kV., as was in fact found with the *D*–47 tube.

We wish to thank Dr. A. Bracken of British Oxygen Research and Development, Ltd., for the helium–butane gas mixtures. The Scott-type counter tube was constructed by Mr. L. D. Kitchen and Mr. S. T. Smith of the Physics Department, King's College Hospital. The Nuclear-Chicago counting equipment was a gift from Miles Ames Laboratories to Prof. C. H. Gray.

METALLURGY

The Delta Plutonium Transition Temperature

SINCE the first reports of the allotropes of the element plutonium[1], one aspect of continuing interest has been the existence of the δ'-phase occurring in the temperature-range 450–480° C. Recent determination of the latent heats of transition of the allotropes of plutonium[2] enable the thermodynamic aspect of the effects of alloying elements (at impurity-level concentrations) on the $\delta \rightleftharpoons \delta'$ transition to be considered.

It has been pointed out that the phase rule, commonly applied in the construction of equilibrium diagrams, is but one of a number of rules all of which are based on the same thermodynamic reasoning[3]. One of these rules is that when a polymorphic reaction occurs in one of the pure components, the initial slopes of the phase boundaries meeting at the transition temperature differ by $(L/RT^2)^{-1}$, where L is the latent heat, T the absolute temperature of the transition and R the gas constant. Applying this rule to the $\delta \rightleftharpoons \delta'$ transition for which L is 17 ± 10 cal./gm.–atom and T is 728° A., the difference in slopes of the phase boundaries is 620° C./atomic per cent. This very high value implies that small quantities of added elements may have a marked effect on the observed transition temperature. For the limiting condition that one of the phase boundaries of the

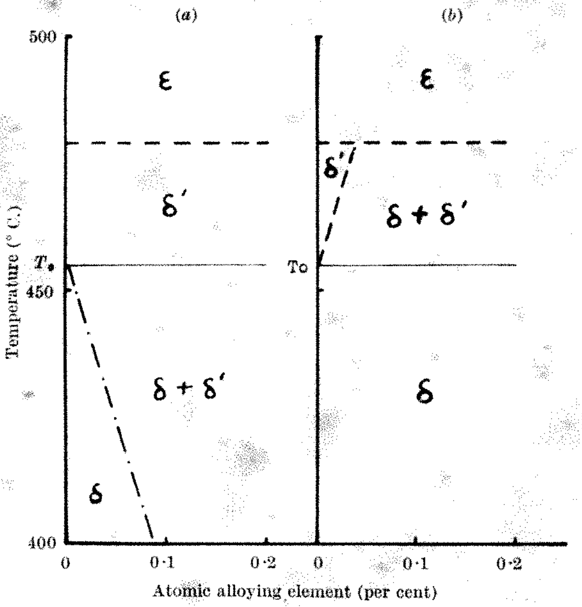

Fig. 1. Limiting cases for the effect of alloying elements on the $\delta \rightleftharpoons \delta'$ transition in plutonium

two-phase region $\delta + \delta'$ has zero slope (thereby minimizing the effect of alloying elements on the transition temperature) the other will have a slope of absolute value 620° C./atomic per cent. In Fig. 1 (*a*), the impurity addition does not affect the lower limit of the pure δ' region, whereas in Fig. 1 (*b*) the region is effectively eliminated by the addition.

The probability of the effect of any specific impurity being one of these limiting cases is thought to be small. Since the slopes of the phase boundaries must both have the same sign, it is probable that in most cases corresponding to Fig. 1 (*a*) the phase boundaries meeting at T (the pure metal transition temperature) will both be tilted downwards. For alloys corresponding to Fig. 1 (*b*), both boundaries will be tilted upwards—making it even less likely that the δ' plutonium structure will be observed. In view of the appreciable concentration of impurities present in nominal 'high purity' plutonium, in those materials where the pure δ'-phase is observed, the situation must be represented by a variation of Fig. 1 (*a*), which is shown diagrammatically in Fig. 2.

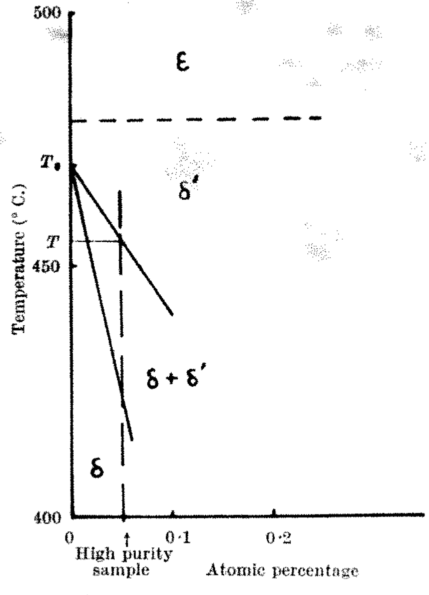

Fig. 2. Possible experimental case

From this figure it is obvious that the transition T observed in 'high-purity' metal may be a low approximation to the true transition temperature T_0. This observation is of particular interest owing to the small temperature-range of existence of δ' (about 25 deg. C.).

CRYSTALLOGRAPHY

Growth of Single Crystals of Copper

In his communication on the growth of single crystals of copper, published in *Nature* of April 2, p. 33, Mr. D. S. Kemsley is good enough to refer to a paper by Andrade and Roscoe[1], in which was described a method suitable for growing single crystals of metals of low melting point.

He makes, however, no reference to a paper published some years later by Andrade and Henderson[2], which specifically states that this method is not suitable for growing crystals of metals of higher melting point and describes a method using a split graphite mould in a high vacuum. This method was used for preparing single crystals of gold, silver and nickel in the first place, and was afterwards used by Andrade and Aboav[3] for preparing single crystals of copper, which proved perfectly satisfactory.

Those who wish to prepare single crystals of copper may possibly find this method simple and well adapted to the purpose.

Crystal Structure of Potassium Trivanadate

When solutions of potassium vanadate are made weakly acid, with pH less than 6·5, the orange polyion $V_{10}O_{28}^{-6}$ is formed. These solutions are unstable, and on long standing or on heating, insoluble light-orange, flaky crystals of potassium trivanadate, KV_3O_8, are precipitated. This compound was evidently first described by Norblad[1].

Buerger precession and Weissenberg X-ray diffraction patterns of crystals of potassium trivanadate show a monoclinic lattice with the dimensions: $a = 7·63$ Å., $b = 8·43$ Å., $c = 4·97$ Å. and $\beta = 96° 45'$. The space group is $P2_1/m$ or $P2_1$, and the unit cell contains 2 formula units. The largest crystals are less than 0·1 mm. in the longest dimension, and grow as irregular stacks of thin platelets parallel to (100), somewhat elongated along the *c* axis. The optical properties were determined as follows (by A. van Valkenburg, U.S. National Bureau of Standards):

$\alpha = 1·78$, $X \sim \perp$ (100), lemon yellow
$\beta = 2·25$, $Y = b$, orange
$\gamma = 2·34$, $Z \sim \parallel c$, orange
$2V = 26°$ (negative)

γ was measured with sulphur-selenium melts, and β was estimated from the other measured results.

The diffraction intensities of the (*hk*0), (0*kl*) and (*h*0*l*) reflexions, which were used for the structure determination, were determined from the multiple photographs by visual comparison with a calibrated strip made with one crystal reflexion. Owing to the imperfect nature of the crystals, these data were not as accurate as one usually expects, so that refinement of the structure was somewhat hampered. The trial structure was obtained from the three Patterson projections and spatial considerations. Refinement of this structure proved to be troublesome by Fourier methods, owing to serious atom overlaps in all three projections. Application of the powerful least-squares programme (which solves the full matrix of the normal equations) written by Busing and Levy of the Oak Ridge National Laboratories for the IBM Type 704 computer, finally brought the agreement between observed and calculated structure factors to a satisfactory state. No evidence has been found to indicate that the structure departs from centrosymmetry, and the accepted space group is $P2_1/m$. At present, the reliability factors are as follows: $R(hk0) = 17·8$ per cent, $R(0kl) = 11·3$ per cent and $R(h0l) = 13·1$ per cent; overall $R = 14·0$ per cent. The corresponding parameters are given in Table 1.

Table 1. PARAMETERS FOR POTASSIUM TRIVANADATE
Space group $P2_1/m$ (Int. Tab. No. 11)

Atoms	*x*	*y*	*z*
2K in (*e*)	0·062	$\frac{1}{4}$	0·945
$2V_1$ in (*e*)	0·577	$\frac{1}{4}$	0·917
$4V_2$ in (*f*)	0·693	0·057	0·441
$2O_1$ in (*e*)	0·415	$\frac{1}{4}$	0·109
$2O_2$ in (*e*)	0·759	$\frac{1}{4}$	0·595
$4O_3$ in (*f*)	0·516	0·101	0·700
$4O_4$ in (*f*)	0·518	0·063	0·441
$4O_5$ in (*f*)	0·744	0·092	0·130

The structure, as illustrated in Fig. 1 projected along the *a* axis, consists of a sheet arrangement of fused VO_6 octahedra, with potassium ions occupying interlayer positions. Two-thirds of these octahedra are linked into zig-zag chains stretched parallel to the *b* axis; the remaining one-third lie on the mirror planes and tie these chains into layers parallel to the *b* and *c* axes. Although the V—O bond-lengths are not accurately known (± 0·1 Å.), it is apparent that the octahedra are highly distorted. For the vanadium atom on the mirror plane, the distances are 1·65, 1·69 (2), 2·01 (2) and 2·24 Å.; for the other vanadium atom they are 1·58, 1·66, 1·85, 2·01, 2·13 and 3·01 Å.

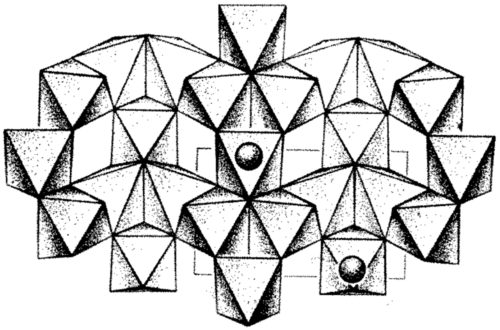

Fig. 1. The layer co-ordination structure of potassium trivanadate projected along the *a* axis. Two of the interlayer potassium ions are shown as shaded circles. (Drawn by H. T. Evans, jun.)

The structure found for KV_3O_8 has been confirmed also for the isostructural CsV_3O_8 by H. T. Evans, jun. (personal communication), and has reached a better degree of refinement, owing to the better quality of crystals formed by the cæsium compound. Details of the analysis of both these structures will be published elsewhere. There is, incidentally, no relation between these structures and that of KCr_3O_8 recently described by Wilhelmi[2].

I wish to express my thanks to J. D. H. Donnay for his encouragement and guidance of the work described; and to H. T. Evans, jun., of the U.S. Geological Survey, who suggested the problem, for his helpful discussions and guidance. Thanks are also due to the latter for providing computer facilities, and to P. O'Hara of the National Bureau of Standards for his assistance with the IBM Type 704 computer.

Electron Microscopy and the Crystal Structure of Indanthrene

IN the course of work on the direct observation of crystal lattices using high-resolution electron microscopy, indanthrene ($C_{28}H_{14}O_4N_2$) has been examined in a manner similar to that used by Menter[1] with phthalocyanine ($C_{32}H_{18}N_8$) and its metal derivatives.

The crystal structure of indanthrene has been ascertained by Bailey[2] using conventional X-ray techniques: he finds the crystal to be monoclinic, space group $P^2{}_1/a$, with two molecules in the unit cell and the following dimensions: $a = 30·83$ Å.; $b = 3·833$ Å.; $c = 7·845$ Å.; $\beta = 91° 55'$ (see Fig. 1).

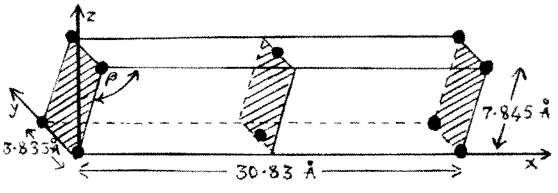

Fig. 1. Indanthrene: the unit cell

The work with the electron microscope bears out those values he obtained for lattice translations *a* and *b*, but, more important, it adds further evidence that images seen in the microscope are in fact images of planes of molecules and are not merely fringes formed by electron diffraction. Labaw and Wyckoff[3], in their study of the derivative indanthrene scarlet *R* ($C_{38}H_{22}N_2O_6$), were unable to use the technique of electron micro-diffraction and left this question unresolved.

Crystals of indanthrene, platy but with very ill-defined terminal faces, were deposited on specimen grids from a suspension in acetone, and examined at high magnification in a Siemens Elmiskop I electron microscope operated at 80 kV. Parallel fringes lying along the length of the crystals were frequently observed (Fig. 2) and comparison of the spacing of these fringes with that of the '$(20\bar{1})$ planes' of platinum phthalocyanine (11·94 Å.) in photographs taken under identical conditions gave a value of 15·2 ± 0·4 Å.

Electron micro-diffraction photographs such as that in Fig. 3 from the circular region of the 'raft' of crystals in Fig. 4 have the characteristic appearance of fibre photographs. Measurements of the distance apart of neighbouring layer lines of the fibre pattern indicate that the maximum period of the lattice structure along the fibre axis is 3·86 ± 0·13 Å., and measurements in a perpendicular direction along the central layer line produce a spacing of 15·51 ± 0·21 Å. Observation of the diffraction pattern in the electron microscope shows that it is only the innermost two spots on the central layer line which are uncovered by the objective aperture in normal microscopy conditions. Thus only the diffracted beams from a structure of period ~ 15·5 Å. are allowed to produce an image on the electron microscope screen after recombination by the later electron lenses.

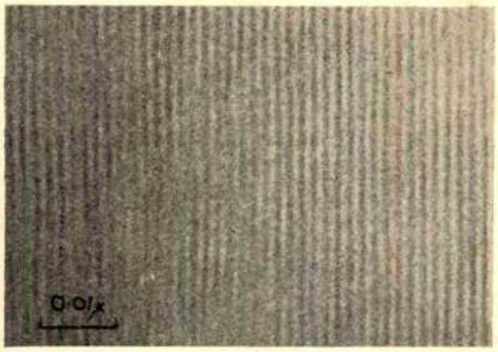

Fig. 2. Electron micrograph of part of a crystal of indanthrene (× 1,000,000)

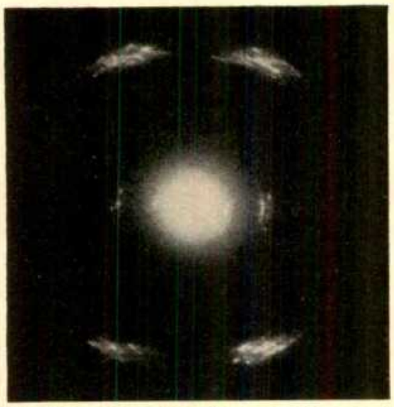

Fig. 3. Micro-diffraction pattern from circular region in Fig. 4

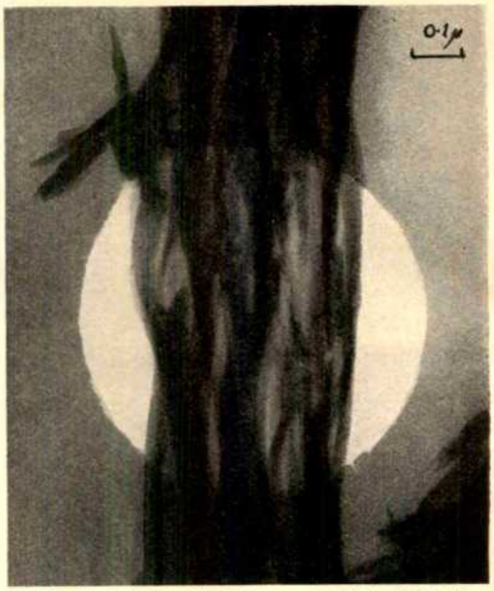

Fig. 4. A 'raft' of indanthrene crystals (× 60,000)

It is compatible with these observations that the crystals examined were platy on {001}, with small {100}, that those planes separated by lattice translations *a*/2 and *b* give rise to the diffraction pattern observed, and that the (200) planes of indanthrene are directly imaged in the electron microscope under normal conditions.

I thank Dr. F. P. Bowden for his help, Dr. J. W. Menter for discussion, the Department of Scientific and Industrial Research for a research grant, and the Imperial Chemical Industries, Ltd., for crystal specimens.

Crystal Structure of Mellitic Acid

IN a recent communication, Bezjak and Grdenić[1] have described the crystal structure of mellitic acid ($C_6(COOH)_6$). I have also recently completed an independent and full refinement of the structure[2]. While there is agreement on the general features of the structure, my conclusions are different, and are that:

(1) The twelve independent C—O bonds are not identical, but have lengths ranging from 1·18 ± 0·03 to 1·34 ± 0·03 Å. (Bezjak and Grdenić quote them all as 1·23 ± 0·01 Å.). The variations of bond-lengths within the carboxyl groups are consistent with the variations in the C—C—O bond angles.

(2) Within each layer there are six inter-molecular contacts of lengths between 2·64 and 2·68 Å. for each molecule. As these are the lengths expected for hydrogen bonds from the infra-red evidence[3,4], and

correspond to the number of hydrogens in the structure, they are assumed to be the hydrogen bonds. The two contacts of 2·68 Å. between oxygens in different layers given by Bezjak and Grdenić are found to be 2·90 and 3·06 Å. by me, and are not considered to be hydrogen bonds.

A further point of more general application may be made concerning the possible ambiguity of structures solved in projection only, when the space group has fairly high symmetry. The present structure serves as an example.

The space group *Pccn* has eight equivalent general positions given by :

$$x,y,z\ ;\ \tfrac{1}{2}-x,\tfrac{1}{2}-y,z\ ;\ \tfrac{1}{2}+x,\bar{y},\tfrac{1}{2}-z\ ;\ \bar{x},\tfrac{1}{2}+y,\tfrac{1}{2}-z\ ;$$
$$\bar{x},\bar{y},\bar{z}\ ;\ \tfrac{1}{2}+x,\tfrac{1}{2}+y,\bar{z}\ ;\ \tfrac{1}{2}-x,y,\tfrac{1}{2}+z\ ;\ x,\tfrac{1}{2}-y,\tfrac{1}{2}+z.$$

If the y co-ordinate is replaced by $\frac{1}{2}-y$, the eight positions become :

$$x,\tfrac{1}{2}-y,z\ ;\ \tfrac{1}{2}-x,y,z\ ;\ \tfrac{1}{2}+x,\tfrac{1}{2}+y,\tfrac{1}{2}-z\ ;\ \bar{x},\bar{y},\tfrac{1}{2}-z\ ;$$
$$\bar{x},\tfrac{1}{2}+y,\bar{z}\ ;\ \tfrac{1}{2}+x,\bar{y},\bar{z}\ ;\ \tfrac{1}{2}-x,\tfrac{1}{2}-y,\tfrac{1}{2}+z\ ;\ x,y,\tfrac{1}{2}+z\ ;$$

which are different in three dimensions, but give the same set of positions in all three axial projections, $0kl$, $h0l$ and $hk0$. This may easily be seen from the two sets of co-ordinates given. Exactly this ambiguity between y and $\frac{1}{2}-y$ exists for each carboxyl group in the crystal structure of mellitic acid, as the carbon framework of each molecule lies approximately in the plane $y = \frac{1}{4}$ or $y = \frac{3}{4}$. Thus whether a carboxyl group is rotated clockwise or anti-clockwise about the C—C bond joining it to the ring depends on whether the oxygens have co-ordinates y or $\frac{1}{2}-y$. With four independent carboxyl groups per molecule and two independent molecules in the structure, there are 2^8 or 256 possible structures which will give identical projections, and they can be distinguished only by using some general reflexions. Between different carboxyl groups within the same molecule, all but four of these possible structures give oxygen–oxygen contacts which are too small. I used $h1l$ and $h3l$ reflexions to distinguish between these four possibilities.

RADIATION CHEMISTRY

Radiation-induced Changes in α-Lead Azide

Using techniques of micro-hardness determination already described[1] and standard methods of X-ray diffraction analysis, preliminary changes in the lattice of X-irradiated α-lead azide have been measured and decomposition products analysed. Specially grown 99·9 per cent pure 1 mm. crystals were used to determine hardness changes and microcrystalline 99·5 per cent pure azide material used in the parameter studies. Nickel-filtered 45-kVp. copper radiation with a half-value layer in aluminium of 0·06 mm. was used to produce and record the parameter changes, whereas somewhat harder radiation with a half-value of 0·09 mm. and from a tungsten tube operated at 50 kVp. was used (*a*) to induce hardness changes and (*b*) to bring about ultimate decomposition of the azide. Approximate dose-rates in each series of experiments were 5·0 × 10² röntgens/min., 2·5 × 10⁴ röntgens/min. and 1·4 × 10⁵ röntgens/min. respectively.

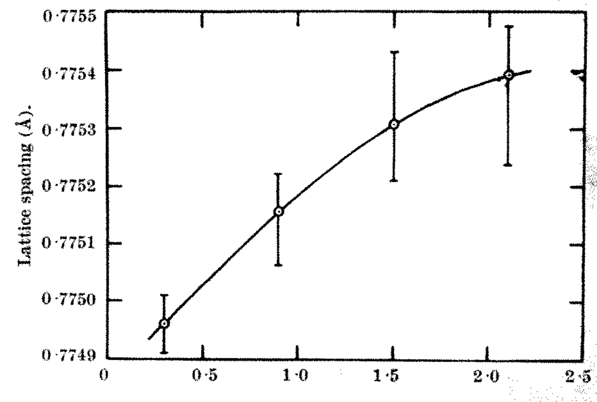

Fig. 1. Mean increase in an unindexed lattice spacing of α-lead azide with X-ray dose, at a dose-rate of 5·0 × 10² röntgens/min. in air. The spread of the results used for each graphical point is indicated

To study parameter changes the highest reflexion recorded with copper $K\alpha_1$ was selected for measurement. This could not be indexed, but was calculated to refer to an uncorrected spacing of $0{\cdot}7749_6$ Å. at 70° F. with a measured temperature coefficient of 0·00002 Å./deg. F. Fig. 1 shows increase in this parameter with increasing X-ray dose. Six trials were carried out and each graphical point is the mean of six determinations with experimental error as shown. Serious loss of line-to-background intensity terminated the series before saturation if any could be effectively observed, and within the scope and experimental accuracy of the work, it was not possible to test critically for any relaxation with time or instability to light. Qualitatively similar results were obtained for other parameters.

Hardness changes for the 013 form ($a<b<c$) of α-lead azide undergoing X-irradiation were measured at 10-gm. load. Five dual trials were carried out, and it was readily apparent that the hardness increases noted were not permanent but

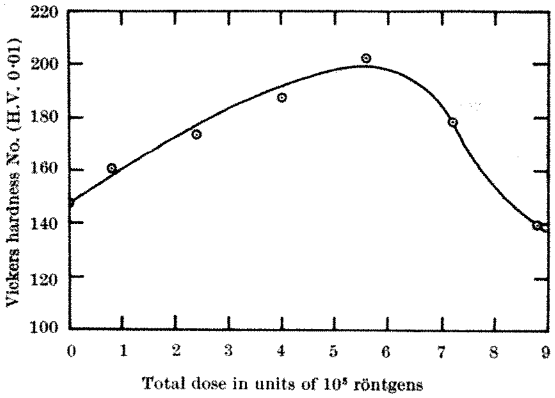

Fig. 2. Showing the increase in Vickers hardness at 10 gm. load for the 013 form of an α-lead azide crystal while receiving X-rays at a dose-rate of 2·5 × 10⁴ röntgens/min. in air

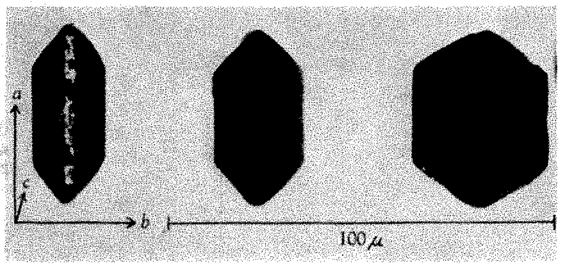

Fig. 3. Showing the anomalous *b*-axis expansion in the habit of a single crystal of α-lead azide receiving X-rays at a dose-rate of $1 \cdot 4 \times 10^5$ röntgens/min. in air

tended to relax with time and even in the dark. Fig. 2 relates hardness to dose for a run in which all operations were carried out with maximum speed. Five indentations were used to derive each graphical point, good consistency being obtained.

Changes in parameter[2] and mechanical properties[3] have already been observed in other irradiated materials and are generally ascribed to vacancy production. If, as is probable, decomposition of α-lead azide proceeds by electron transfer from azide ions to liberate free nitrogen, this would result in vacancy production consistent with the results obtained.

Optical, gravimetric, and X-ray methods were used to study more extensive X-ray damage in the α-lead azide, both in air up to a total dose of $3 \cdot 4 \times 10^8$ röntgens and corresponding to more than 97 per cent destruction of the azide, and in a number of other atmospheres. Although the ultimate X-ray product in vacuum or under an inert atmosphere is necessarily lead, this is not encountered in the presence of carbonic acid or of water. Thus, X-ray studies show that the stable end-product of X-ray decomposition in normal air is basic lead carbonate of the formula $2PbCO_3.Pb(OH)_2$, whereas in severe deficiency of carbon dioxide but excess of water vapour, amounts of basic lead azide of unestablished formula[4] are formed. The latter may be finally converted into basic lead carbonate by X-irradiation in normal air.

X-ray examination of a single crystal of α-lead azide undergoing decomposition to disoriented basic lead carbonate shows that the conversion is complex. After a dose of $6 \cdot 7 \times 10^7$ röntgens there is evidence for partially disoriented residual lead azide together with a disoriented unidentified phase. Higher doses produce a further unidentified phase before stable basic lead carbonate is finally formed.

These features, together with the anomalous *b*-axis habit expansion of the decomposing crystal (Fig. 3), have not yet been satisfactorily explained.

We are indebted to the Ministry of Aviation Explosives Research and Development Establishment for the supply and chemical analysis of the α-lead azide starting material, and to the War Office Armament Research and Development Establishment Chemical Services Branch for miscellaneous analyses.

Modes of Radiation-induced Cross-Linking in Hydrocarbon Polymers

Since the earliest observations[1,2] on the cross-linking of organic polymers by ionizing radiation, much research has been devoted to this phenomenon, but there remains no generally accepted mechanism applicable to all polymers[3]. For polyethylene it has been proposed[4] that linkages between molecules arise from three independent processes:

(*a*) By the direct action of ions according to either an ion–molecule–electron reaction as originally suggested by Dole[1] and represented in (1):

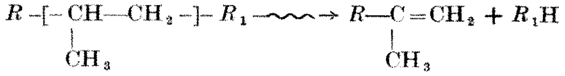
(1)

or by an ion–molecule process followed by subsequent neutralization of the product ion by its cognate electron[5,6].

(*b*) From the interaction of free radicals of low mobility primarily formed in crystalline regions of the polymer[7], as in a post-irradiation fusion of the solid.

(*c*) As a result of the decay of unsaturation initially present and of the unsaturated groups formed during radiolysis[8]; in this case an end- or cross-link would result depending upon the position of the unsaturated group in the polymer. It has been postulated that the mechanism of this process occurs by excitation energy transfer from the main polymer chain[8,9].

A recent paper by Black and Lyons[10] on the radiolytic changes incurred in polypropylene indicates that the formation of vinylidene double bonds corresponds to the occurrence of main-chain fracture according to (2):



$$R\text{-[-}\underset{\displaystyle CH_3}{\underset{|}{CH}}\text{—}CH_2\text{-]-}R_1 \rightsquigarrow R\text{—}\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2 + R_1H \qquad (2)$$

Further, at doses exceeding $5 \cdot 0 \times 10^{21}$ eV. gm.$^{-1}$, it is shown that the sol fraction–dose relationship for this irradiated polymer is in accordance with an expression derived by Charlesby[11] on the assumption that the ratio of cross-linking to chain fracture approaches unity. These results are interpreted[10] in terms of a mechanism whereby an excited intermediate state of the polymer leads either to fracture F or cross-linking C, the latter process depending upon the concentration $[F]$ of stable chain fragments, that is, vinylidene groups, arising from previous fracture processes during irradiation.

If the processes of vinylidene group growth and decay in polypropylene are considered analogous to the kinetics of *trans*-vinylene formation in polyethylene[8], the corresponding relation:

$$\frac{dF}{dD} = \varphi_f - k_f[F] \qquad (3)$$

would be expected to hold where φ_f refers to the initial rate of chain fracture and k_f is the decay constant for vinylidene groups leading to cross-linking. Since the vinylidene groups are located at the ends of fractured chains, that is, *iso*propenyl groups, it is more correct to refer to their disappearance by end-linking. In formulating equation (3) the process leading to fracture as represented by φ_f is considered to be independent of the magnitude of the subsequent decay process governed by $k_f[F]$ and thus differs from the competitive reaction mechanism envisaged by Black and Lyons[10]; studies on polyethylene have shown[8] that the initial rate of *trans*-vinylene formation is not reduced by a higher initial vinyl group concentration in the polymer so there would appear to be no direct competition between unsaturation formation and disappearance in this system. A test of equation (3) is provided by the data of Black and Lyons in Fig. 4 of their paper[10]; neglecting the two points at low-irradiation doses, the remainder of the results conform to a reasonable linear relation between $\frac{dF}{dD}$ and $[F]$ with a k_f value of 0·094 Mrad^{-1} or 1·51 × 10^{-21} gm. eV.$^{-1}$. It is of special interest that this latter value compares closely with the decay constant of 1·49 × 10^{-21} gm. eV.$^{-1}$ previously obtained for initial vinylidene decay in a sample of high-pressure polyethylene[8]. At high doses it follows directly from equation 3 that the rate of cross-linking would equal the rate of fracture at a limiting concentration of vinylidene groups formed by fracture, in agreement with experiment.

The evidence cited suggests that the cross-linking of polypropylene depends mainly on the process (*c*) above; by contrast, the cross-linking of saturated polyethylene chains in the initial stages of irradiation proceeds chiefly according to (*a*) and (*b*), the latter contribution depending upon the crystallinity of the sample and the post-irradiation treatment[7,12]. In general, the importance of (*c*) will depend on the concentration of unsaturation in the polymer, whether initially present or formed during irradiation, and hence on the irradiation dose. The relatively low cross-linking yields reported for highly unsaturated polymers (rubber, polybutadiene, etc.) by comparison with the measured decay of unsaturation[9,13] suggest that in such cases the main reaction is the formation of internal links by process (*c*) within the polymer chains aided by the coiled configuration of the molecule in the amorphous state[14]; in this connexion it is noteworthy that Roberts and Mandelkern[15] have observed that the cross-linking of rubber is much increased if the irradiation is carried out on the highly oriented polymer whereas for polyethylene the cross-linking is greater in the liquid state[4,7].

GEOCHEMISTRY

A New Interpretation of the Mullite Problem

The published phase diagrams for the Al_2O_3–SiO_2 system have been many and varied. Bowen and Grieg[1] maintained that mullite of invariable composition $3Al_2O_3.2SiO_2$ (71·8 weight per cent Al_2O_3) is the only stable alumino-silicate found at high temperatures in this system. Several workers have since found homogeneous mullites containing from 75 to as much as 82·6 per cent Al_2O_3, and it is at present generally accepted that continuous mullite solid solutions exist at least over the range $3Al_2O_3.2SiO_2$–$2Al_2O_3.SiO_2$ (71·8–77·3 per cent Al_2O_3). Some investigators also claim the existence of mullites intermediate in composition between sillimanite ($Al_2O_3.SiO_2$) and $3Al_2O_3.2SiO_2$, although continuous solid solution between these compositions has never been authenticated. More recently, the melting behaviour of mullite has been disputed, some workers adhering to Bowen and Grieg's belief that mullite melts incongruently, whereas others maintain that no decomposition into corundum and liquid occurs during melting, and that therefore mullite melts congruently.

Recently it has become possible to observe the behaviour of melts directly by hot-stage microscopy, instead of having to rely solely on the indirect techniques of quenching or thermal analysis used by previous investigators. The application of this new technique to a study of the Al_2O_3–SiO_2 system appears to have resolved some of the outstanding questions, particularly in regard to the melting behaviour and constitution of mullite. Briefly, direct observations have been made on $3Al_2O_3.2SiO_2$ compositions near the liquidus temperature which show repeatedly that corundum crystals, whether present in the starting material or obtained by appropriate undercooling of the melt, are entirely dissolved by the liquid in the presence of residual mullite. The survival of corundum has been observed only when prolonged heating has caused the melt composition to change through volatilization of silica, or when the temperature of the melt has been increased without regard to the much slower rate at which corundum dissolves as compared with mullite.

These observations therefore support the view that the $3Al_2O_3.2SiO_2$ composition, under conditions of equilibrium, does not form corundum during melting; the corollary, that mullite melts congruently, is also disproved, however, by the following observations. Heated melts of $3Al_2O_3.2SiO_2$ composition tend to lose silica by volatilization. Despite this tendency, such melts contain an appreciable amount of siliceous residual glass after mullite single crystals have been grown from them on the microscope hot-stage. The inference that these mullite single crystals must be more aluminous than the parent composition has been checked by chemical separation and analysis. Such crystals were found to contain 77·2 per cent Al_2O_3 (cf. $2Al_2O_3.SiO_2 \equiv 77·3$ per cent and $3Al_2O_3.2SiO_2 \equiv 71·8$ per cent Al_2O_3). Refractive indices of these crystals measured in sodium light gave $N_\alpha = 1·638$, $N_\gamma = 1·653$. Identical indices were reported by Wright[2] for crystals obtained by fusion of an $Al_2O_3.SiO_2$ composition, and the same figures have been quoted by Larsen and Berman[3] for 'artificial mullite'. Different heat treatments have been used to prepare mullites the analysed Al_2O_3

contents of which have ranged from 79·5 down to 75 per cent, the median being represented approximately by $2Al_2O_3.SiO_2$ (77·3 per cent). The refractive index measurements show an apparently linear relation with composition as shown in Fig. 1. From this diagram the supposedly constant refractive indices of mullite reported by Bowen and Grieg[1] could in fact represent mullites containing some 75–77 per cent Al_2O_3, if allowance is made for the stated accuracy of their measurements ($N_\alpha = 1·642$, $N_\gamma = 1·654$ ($\pm 0·003$)).

The mullite containing the least amount of Al_2O_3 (75 per cent) was crystallized from a $CaO–Al_2O_3–SiO_2$ melt over the temperature-interval 1,550–1,500° C., that is, at a temperature below the reported solidus for the system $Al_2O_3–SiO_2$. It is probable, therefore, that the mullites the optical properties of which have been described by other investigators lie much closer in composition to $2Al_2O_3.SiO_2$ than $3Al_2O_3.2SiO_2$, and that the synthesis of true $3Al_2O_3.2SiO_2$ is only likely to be successful at temperatures well below the $Al_2O_3–SiO_2$ solidus.

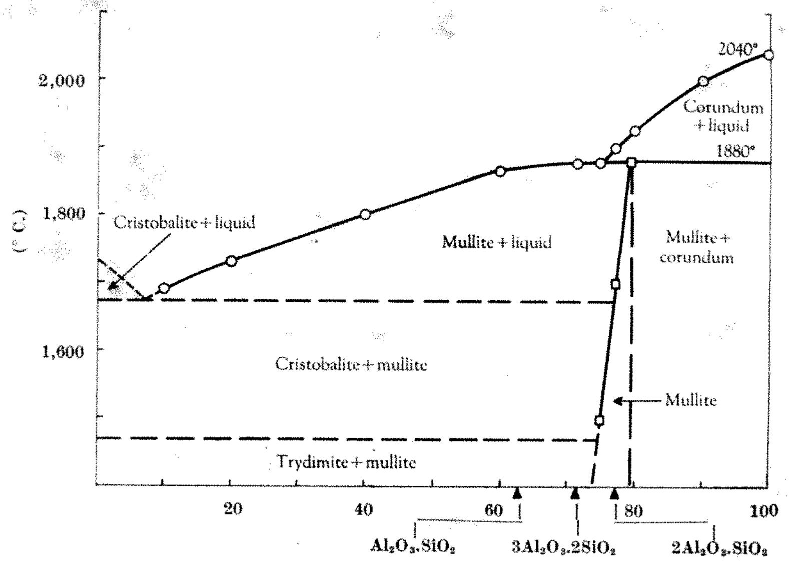

Fig. 2. Redetermined equilibrium diagram for Al_2O_3—SiO_2

During the investigation some unusual forms of mullite were encountered. Seen under the microscope, these appeared to be almost or completely homogeneous, and they were characterized by lowered refractive index, birefringence, and $2V$ as compared with normal mullites. They occurred in rapidly cooled melts of more siliceous composition than $3Al_2O_3.2SiO_2$, and are attributed to the almost or completely sub-microscopic intergrowth of mullite and glass. It is hoped to obtain confirmation of this theory by X-ray examination, because a mixed phase of this type apparently cannot be differentiated by optical or chemical methods.

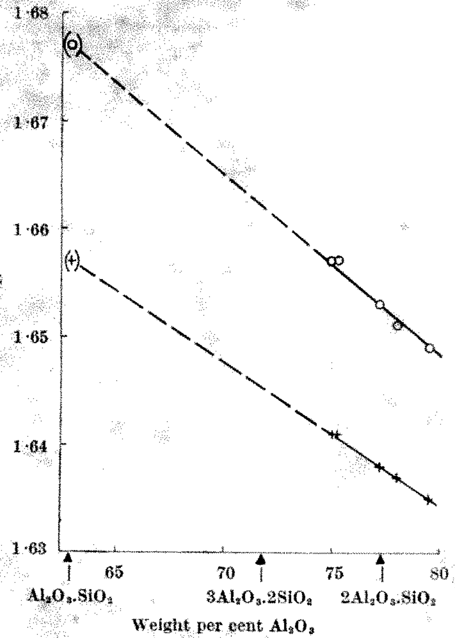

Fig. 1. Variation of refractive index with mullite composition

Liquidus temperatures have been determined by hot-stage microscopy for a major part of the $Al_2O_3–SiO_2$ system, as shown in Fig. 2. The mullite primary phase region, including the composition $3Al_2O_3.2SiO_2$ which has no special significance, ends at about 75 per cent Al_2O_3, where mullite is transformed peritectically to a mixture of corundum and liquid at 1,880° C.

A detailed account of this work is being presented at the Seventh International Ceramic Congress, London, in May.

CHEMISTRY

Reaction of Active Nitrogen with Polyethylene

THE nature of active nitrogen, the mechanism of its afterglow[1], and its gas phase reactions with organic molecules[2] have been discussed. I have now investigated a heterogeneous active nitrogen reaction at a polymer surface.

'Marlex-50' polyethylene was chosen as the polymer because it has a simple, well-defined structure. It is a high-density, unbranched, highly crystalline polyethylene with polymer chains terminating in one methyl and one vinyl group. Thin sheets of this material were exposed in a flow system to active nitrogen, which was produced by a condensed discharge. Reactions proceeded for periods up to 2 hr. at a pressure of 1·9 mm. mercury, and at temperatures between 39° and 120° C. Condensable products were trapped and analysed quantitatively by vapour phase chromatography and infra-red spectroscopy. The latter was also used to determine the concentration of vinyl bonds in the polymer. Solubility tests established the extent of cross-linking. The concentration of active nitrogen was obtained from the intensity of the afterglow, which was calibrated by the titration reaction of active nitrogen with nitric oxide[3]. The results of a typical experiment are given in Table 1. The activation energies of the various experimentally determined processes and their probable errors are listed in Table 2.

Table 1. TYPICAL REACTION OF ACTIVE NITROGEN WITH POLYETHYLENE

	Product formation :
Temperature, 89° C.	Hydrogen cyanide, 84 per cent
Duration, 60 min.	Cyanogen, 16 per cent
Flow of molecular nitrogen, 610 ml./min.	Total nitrogen equivalent, 60·0 μlitre
	Gel formation, 7·1 per cent
Flow of active (atomic) nitrogen, 14·2 ml./min.	Vinyl decrease, 24 per cent
Conversion, $N_2 \rightarrow 2N$, 1·1 per cent	
Conversion $N \rightarrow N$ equivalent, $0·9 \times 10^{-2}$ per cent	

Table 2. ACTIVATION ENERGIES (IN KCAL./MOLE)

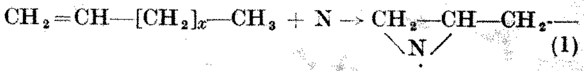
Hydrogen cyanide formation	3·0 ± 0·5
Cyanogen formation	1·9 ± 0·7
Formation of total nitrogen equivalent	2·5 ± 0·6
Vinyl decrease	3·1 ± 1·2
Cross-linking (gel formation)	6·3 ± 1·9

The condensable gas products, the quantity of which varied from 20 to 80 μlitres, contained about 80 per cent hydrogen cyanide, 20 per cent cyanogen, and only traces of ammonia. No derivatives of hydrocarbon fragments were found. Previous reactions of hydrocarbon with active nitrogen in the gas phase gave a maximum formation of 2 per cent cyanogen. In the present less-reactive polyethylene system, the concentrations of hydrocarbon fragments and hydrogen atoms were much smaller than in the comparable gas-phase reaction. The polymer chains were broken but were not fragmented too extensively, and many of the hydrogen atoms were consumed in the process of cross-linking by hydrogen abstraction. Thus, relatively more CN radicals were available for the formation of cyanogen. This also indicated that the CN radical is an important precursor of secondary products in the gas reaction. All C=C double bonds are convenient sites for addition of nitrogen. In 'Marlex-50', 95 per cent of the double bonds are vinyl groups[4], which may initiate a mechanism of chain-unzipping. The remaining 5 per cent of double bonds are vinylene and vinylidene groups, addition to which may lead to scission of the chains. Chain fragments, in turn, will unzip or cross-link.

Up to 10 per cent of the polyethylene was cross-linked by the active-nitrogen reaction. Weight losses amounted to less than 1 per cent. Hence the extent of cross-linking indicated that the reaction was propagated below the surface, either by nitrogen atoms, hydrogen atoms, or free radicals. A mechanism of diffusion would be a reasonable explanation for this observation.

There is a parallelism between reactions due to active nitrogen and those induced by radiation because the physical and chemical properties of a polymer after the nitrogen reaction resemble those after a mild treatment with radiation. Hence, the results of the present investigation can be interpreted by combining the unified mechanism of active nitrogen reactions[2] with established mechanisms of polymer reactions in radiation[5].

(1) *Formation of nitrogen complex.* In the primary process a nitrogen atom can form one of three reaction complexes, at either end of the polyethylene ('Marlex-50') chain or within the chain ; for example :



$$CH_2{=}CH{-}[CH_2]_x{-}CH_3 + N \rightarrow \underbrace{CH_2{-}CH}_{\dot{N}}{-}CH_2{-} \qquad (1)$$

(2) *Formation of nitrogen-containing compound or radical.* Attack on the double bond may be slightly favoured, but all three cases are energetically favourable. The nitrogen atom will attack the C—C bond, rather than the C—H bond and this will lead to splitting-off of either the CN radical, or hydrogen cyanide and hydrogen atoms. The products of reaction 1 may be a new vinyl bond (chain-unzipping) or a chain terminating in a free radical.

$$(1) \rightarrow HCN + H \text{ (or } CN + 2H) + CH_2{=}CH{-} \text{ (chain-unzipping)}$$

or

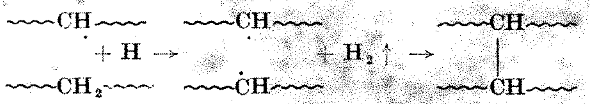
$$(1) \rightarrow HCN \text{ (or } CN + H) + .CH_2{-}CH_2{-} \text{ (free radical chain-termination)}$$

(3) *Hydrogen abstraction from polyethylene chain.* Hydrogen is not directly abstracted by nitrogen atoms. This is made possible, however, by the action of the hydrogen atoms liberated in the formation of free radicals :

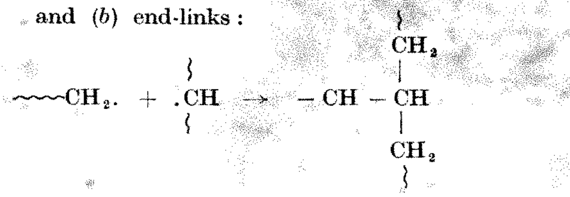
$$-CH_2{-}CH_2{-}CH_2{-} + H \rightarrow -CH_2{-}\underset{\cdot}{CH}{-}CH_2{-} + H_2$$

Cross-linking requires the existence of the radical $-CH_2{-}\underset{\cdot}{CH}{-}CH_2{-}$, because chain ends, such as $.CH_2{-}CH_2{-}$, could only couple or unzip. The evidence of cross-linking in depth as shown by gel tests, together with the larger activation energy of cross-linking, points to diffusion of nitrogen (and hydrogen) atoms into the polymer. With free radical chains of two types present, $-CH_2{-}\underset{\cdot}{CH}{-}CH_2{-}$ and $.CH_2{-}$, two mechanisms of cross-linking are possible :

(*a*) Cross-links of neighbouring chains :



and (*b*) end-links :



I am grateful to my colleagues at the General Electric Research Laboratory for advice and assistance in the course of this work. Special thanks are due to Dr. H. A. Dewhurst for valuable discussions and his continued interest.

Broadening of the Water Proton Line in High-Resolution Nuclear Magnetic Resonance Spectra of Starch Gels

Reports in the literature of measurements of proton magnetic resonance absorption for starch–water systems have been confined to dilute solutions[1], to starch suspensions in water[2] and to native starch granules containing up to 15 per cent water of crystallization[3]. In this communication we are reporting measurements made on suspensions containing 8 per cent–40 per cent starch and on the gels made by heating these suspensions at 80°. These results are the first to be recorded on starch-gels, and from the broadening of the water line on gelation we have postulated that the effect of hydration on the nuclear magnetic resonance band extends considerably beyond the water which is directly hydrogen bonded on to the starch hydroxyls.

At temperatures between 20° and 50° C. water is absorbed into the amorphous regions of the granules, which swell about 30 per cent by volume[4]. The crystallites remain largely intact, but on heating the suspension at a temperature above 60° some of the crystallites are disrupted, and the granules can swell to about 10 times their original volume if there is sufficient water available. Provided the starch concentration is sufficiently high (usually about 12 per cent with wheat starch) the swollen particles adhere together to form a coherent gel. All the mixtures used in these experiments formed a coherent gel at 80°, apart from the 8 per cent suspension which on heating formed an aqueous suspension of swollen granules.

The nuclear magnetic resonance spectra were obtained on the prototype of the Fairey spectrometer. This comprises a permanent magnet with 4-in. diameter pole faces, a gap of 0·72 in. giving a field of approximately 3,800 gauss at which the ^{1}H frequency is 16·1 Mc./s. The samples were contained in soda glass tubes of 5·2 mm. outside diameter and approximately 3 mm. inside diameter. Sample spinning at 3,000 r.p.m. was employed and a resolution of 1 part in 10^7 was attained under these conditions. All measurements were made at 35° C. The gels were made by heating the suspensions in the soda-glass tubes for 10 min. at 80°. The gels were then equilibrated for 15 min. in the nuclear magnetic resonance spectrometer at 35° C. before measurements were made.

Symmetrical gaussian curves were obtained at all concentrations, and their widths were measured at half-peak heights.

In all these suspensions and gels the proton magnetic resonance consists of a narrow line (0·4–1·35 p.p.m. wide) due to protons in the water, superimposed on a very broad band (> 1,000 p.p.m.) due to protons on the starch. The measurements made all refer to the water line.

Table 1

Starch (per cent)	Line width (p.p.m.) Suspension	Gel
0	0·4 (pure water)	
8·2	0·45	0·45
15·0	0·45	0·61
25·8	0·43	1·06
25·8*	0·41	1·31
25·8†	0·45	0·68
40·1	1·35	1·12

* Wheat starch in 1 per cent sodium dodecyl sulphate.
† Waxy maize starch (100 per cent amylopectin) in water.
The remaining samples are wheat starch in water.

The suspensions containing up to 26 per cent starch showed a band of similar width to pure water, confirming the results of Shaw and Elsken[2].

However, on gelling there was a marked broadening which increased with increased starch concentration.

Broadening in this type of system could be due to three possible causes: (*a*) A decrease in the spin lattice relaxation time (T_1) as a result of an increase in the micro-viscosity of the water[5]. In gels this is generally of the same order as the viscosity of pure water, and must of course be distinguished from the bulk viscosity of the gel, which is very much higher than that of water. (*b*) Exchange between protons in liquid water and those in hydrate complexes, as proposed, for example, in octylamine–water mixtures[6] and in aqueous solutions of aluminium chloride[7]. (*c*) Exchange between water protons and starch hydroxyl protons.

In these mixtures the ratio of starch to water hydroxyl groups is too low to have much effect and the broadening is probably due largely to the extra binding of water into a four co-ordinated water lattice. This will increase the water line width due to factors (*a*) and (*b*). Pure water at 35° C. contains scarcely any molecules in this compact state; but there are several examples of hydrated macromolecules increasing the order of the water lattice[8], and in fact this explanation has been proposed to explain the broadening of the nuclear magnetic resonance water band in aqueous solutions of deoxyribonucleic acid[1].

The four co-ordinated water lattice is nucleated from water directly hydrogen bonded on to the starch hydroxyls and extends beyond the immediate neighbourhood of the starch. It is clear that the line width will increase with increased hydration, and hence it is not surprising that a broadening occurs on gelation. The broadening is greater in gels containing sodium dodecyl sulphate, which is known to increase starch swelling[9] at 80°.

The band-width depends partly on the amount of water which is bound into the more highly ordered lattice and also to some extent on the mobility of the macromolecule from which the water lattice is nucleated. In this connexion it is significant that the line width of a gel containing 26 per cent of waxy maize starch (100 per cent amylopectin) is considerably lower than that of the corresponding wheat starch gel. Waxy maize starch has less tendency to crystallize due to the higher proportion of branched-chain molecules. This will affect the line width in two opposing ways. Increased hydration will tend to broaden the water line, but this is more than offset by the increased mobility of the macromolecules.

The 40 per cent suspension, unlike the more dilute suspensions, gave a broader line than pure water. Presumably at this high concentration there are sufficient hydroxyls in the granules available for hydration to increase the structure of most of the water since there was no narrow 'free water' line superimposed on the broader line. On gelation there was actually a decrease in line width. This can be attributed to the increased mobility of the macromolecules in the gel, which is in agreement with results obtained from elasticity measurements[9].

In conclusion we can say that the width of the water line in starch gels and suspensions depends partly on the degree of hydration, which governs the number of molecules in a more highly ordered lattice than normally prevails in pure water, and partly on the mobility of the macromolecules on which the water is solvated. At the lower starch concentrations the most important change on gelling is an increase in hydration due to the swelling of the granules. At the high concentration any effect on gelation due to increased hydration is more than offset by the increased mobility of the macromolecules, which causes a narrowing of the water band.

The 'Irving–Williams' Order in the Metal-ligand Stretching Frequencies of Some Metal Hydrazine Complexes

MANY infra-red spectra of metal complexes have been examined in the 2–15μ region, but until now very few co-ordination compounds have been studied in the cæsium bromide region in which some metal-ligand atom-stretching frequencies are expected[1]. Furthermore, no correlation between the frequency of this vibration and the nature of the metal has been found[2].

We have measured the infra-red absorption spectra in the 15–35μ zone of the hydrazine complexes of the 3*d* sub-group metals of the general formula $M(N_2H_4)_2Cl_2$. The two bands in the 660–518 and 440–343 cm.$^{-1}$ regions have been assigned to the N_2H_4 rocking and to the M—N stretching vibrations, respectively. The sequence of these frequencies agrees closely with the 'Irving–Williams' order of the stability of bivalent metal complexes: manganese < iron < cobalt < nickel < copper > zinc (ref. 3).

In Table 1 the observed infra-red frequencies are recorded.

It is interesting to compare such frequencies with the strengths of the M—N bonds in complexes having four such co-ordinate links. As a measure of the bond energy, the heats of formation in aqueous solution of the *bis*-ethylenediamine metal ions, $M(\mathrm{en})_2^{2+}$ (ref. 4), have been used (Fig. 1). The M—N stretching and the N_2H_4 rocking frequencies plotted against the ΔH_{1-2} values lie on two straight lines.

Table 1. N_2H_4 ROCKING AND M—N STRETCHING FREQUENCIES FOR $M(N_2H_4)_2Cl_2$ COMPLEXES

Mn++	Fe++	Co++	Ni++	Cu++	Zn++		Type of vibration
518	554	582	613	660	580	cm.$^{-1}$	N_2H_4 rocking
343	369	388	409	440	385	cm.$^{-1}$	M—N stretching

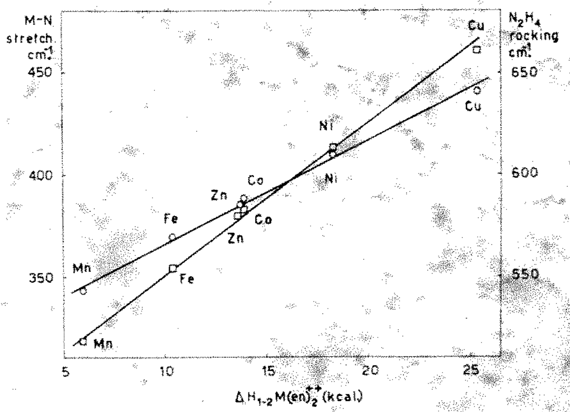

Fig. 1. Graph of the N_2H_4 rocking (□) and M—N stretching (○) frequencies versus the heats of formation of $M(\mathrm{en})_2^{2+}$ complex ions

Analogy to the Kirkendall Effect in the Gas Phase

THE Kirkendall effect[1] was first observed as a movement of fine molybdenum wire markers in a contact plane between brass and copper during interdiffusion. If diffusion occurs by a random walk movement of individual atoms, then, no matter what theory is employed for their detailed motion, it is difficult to see how it could produce movement of markers. Darken[2] considered that diffusion of copper and zinc occurred in opposite directions, at independent rates, and that the difference was compensated by a 'bulk flow'. If it fails to occur, voids are left behind by the more rapidly moving component, and this result of diffusion in metals has in fact been observed[3].

The concepts used by Darken were also developed by Hartley and Crank[4] for liquids, and their consequences have recently been studied in this Laboratory[5]. Lately, however, Adamson[6] failed to observe the Kirkendall effect in liquids, using colloidal particles as markers in sucrose solutions. Now, as Darken's concepts do not depend upon mechanism, they should be equally applicable to solids, liquids and gases[7], and we decided therefore to find if the Kirkendall effect could be demonstrated in gases.

A Loschmitt cell was used consisting of two glass cylinders (4 in. diameter, 7 in. length) which were sealed into two circular plane steel plates. By turning one plate over the other, the gases formed a diffusion boundary of sufficiently large area to make wall effects negligible. The gases used were CF_2Cl_2 and hydrogen, to give widely different diffusion-rates. As marker, ammonium chloride smoke was used, formed by adding about 1 per cent hydrochloric acid to CF_2Cl_2 in the lower cylinder and 1 per cent ammonium to hydrogen. Fig. 1 shows photographs of the movement of the smoke, together with a stopwatch to indicate the elapsed time. It is considered that these provide evidence for the Kirkendall effect in gases. Hydrogen diffuses rapidly into the lower cylinder, and the resulting increase of pressure causes an upward bulk flow of the gas from this cylinder, carrying the smoke particles with it. The cloud does not move as a thin layer, since it consists of particles of various sizes which are settling under gravity. Some even fall almost at once into the lower cylinder and form a faint cloud there. In the following, only the movement of the finest particles at the top boundary of the cloud will be considered. No upward movement of a smoke formed at the boundary was observed when both cylinders contained CF_2Cl_2, with the same concentrations of hydrochloric acid and ammonia as before. A cloud formed in the lower cylinder as before due to larger particles falling rapidly, but the top of the cloud was sharp and settled with a slow, uniform velocity.

Some approximate calculations indicated that the rate of movement of the boundary was of the correct order. If the intrinsic diffusion coefficients of hydrogen and CF_2Cl_2, respectively, are denoted by D_A and D_B, Darken showed that, if N_A is the mole fraction of A in the boundary, and v is the rate at which the boundary is moved by bulk flow :

$$v = (D_A - D_B)\,\frac{\partial N_A}{\partial x}$$

For cylinders of infinite length :

$$\frac{\partial N_A}{\partial x} = \frac{N_{OA}}{2}\,\frac{1}{\sqrt{\pi D_{AB} t}}$$

where N_{OA} = initial value of hydrogen = 1, and D_{AB} = interdiffusion coefficient.

Thus, if x_m equals shift of boundary in time t:

$$x_m = \int_0^t v\,\mathrm{d}t = \frac{(D_A - D_B)}{\sqrt{\pi D_{AB}}}\cdot\sqrt{t}$$

The value of D_{AB} has been shown in this laboratory to be about 0·4 cm.²/sec., and it can readily be proved that, for this value, the assumption of infinite length for the cylinders is approximately valid up to $t = 200$ sec. Assuming that movement of the boundary is given by the surface of the smoke cloud, it can be seen in Fig. 2 that x_m versus $\sqrt{t}$ gives a reasonably straight line. From its gradient, a value of $(D_A - D_B) \simeq 0\cdot43$ was obtained. This is probably low, since the cloud was sedimenting. A correction was attempted by measuring the rate of sedimentation at the end of the experiment and using this to calculate the distance it would fall in time t. The corrected values in Fig. 2 show an upward curvature from a straight line, indicating an over-correction, as would be expected if particles were coarser when sedimentation was measured than when first formed in the early stages of a diffusion experiment. The gradient at the lower part of the corrected curve corresponds to $(D_A - D_B) \simeq 0\cdot63$.

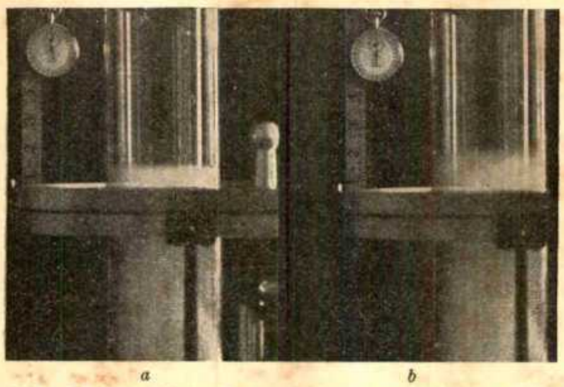

Fig. 1. Position of the smoke stream after 59 sec. (*a*) and 150 sec. (*b*)

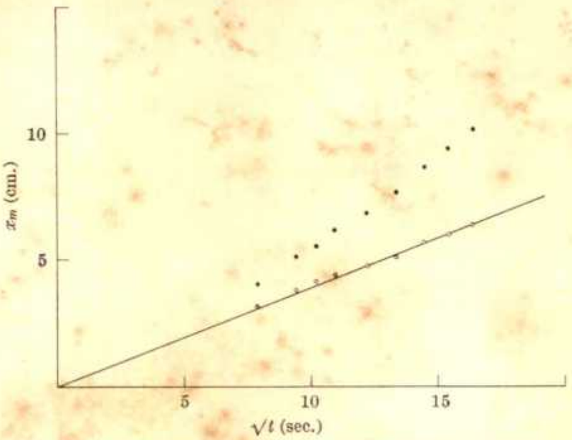

Fig. 2. Upward movement of the smoke boundary. ○, Uncorrected position ; ●, corrected position

Values of D_A and D_B have not been measured, but the self-diffusion coefficient for hydrogen is about 1·3 cm.²/sec. and a value of about 0·04 cm.²/sec. can be calculated for CF_2Cl_2[8]. For gases, the intrinsic diffusion coefficient of a component equals its self-diffusion coefficient[7], and the difference of the self-diffusion coefficients of components in a 50 per cent mixture, corresponding to the diffusion boundary, should be about half the difference for the two pure gases, that is, about 0·7 cm.²/sec. Within the limitations of the experiment, therefore, the agreement is reasonably good.

Though the observed motion of smoke particles supports the concept of a bulk flow as part of an interdiffusion process, Waldmann[9] has put forward a theory for such motion which does not require the assumption of a bulk flow. Parameters to apply his equation quantitatively are not available, but it would seem that his effect should be of a similar order to that given by Darken's equation.

A Model to account for the Production of Vibrationally Hot Molecules in Free-Radical Reactions

THE application of the flash photolysis technique to the study of the photodecomposition of molecules like ozone[1,2], nitrogen dioxide[3] and chlorine dioxide[3], by Norrish and co-workers, has revealed the occurrence of a very unusual series of reactions of the general type:

$$A + BCD \rightarrow (AB)^* + CD + \text{heat}$$

in which a large proportion of the heat of reaction remains concentrated as vibrational energy in the newly formed bond $A—B$. Table 1 summarizes the known reactions of this type, together with two apparently analogous reactions in which no vibrationally excited AB has been detected.

Table 1

Reaction	Excited molecule produced	Maximum energy of vibration (kcal./mole)
$O + ClO_2 \rightarrow O_2 + ClO$	O_2	34
$O + NO_2 \rightarrow O_2 + NO$	O_2	34
$O + O_3 \rightarrow O_2 + O_2$	O_2	63
$Cl + O_3 \rightarrow ClO + O_2$	ClO	12
$Br + O_3 \rightarrow BrO + O_2$	BrO	8
$H + O_3 \rightarrow HO + O_2$	HO	75
$I + Na_2 \rightarrow NaI + Na$	NaI	?
$O + SO_2 \rightarrow SO + O_2$	none	—
$O + Cl_2O \rightarrow O_2 + Cl_2$	none	—

Up to the time of writing no model has been proposed which could be used either to correlate the experimental evidence tabulated above or to rationalize the 'abnormal' behaviour shown in such reactions[4]. This communication describes the development of such a model.

There are three points of similarity in all the reactions which yield vibrationally excited molecules; it is always the newly formed molecule, AB, which is vibrationally excited; the number of vibrational quanta possessed by AB is always far in excess of that 'allowed' by equipartition and Maxwell–Boltzmann energy distribution restrictions, so that clearly the collisions between the atom A and the molecule BCD must be of a specialized type; the bond-strength $B—C$ is moderate or weak.

In order to correlate these observations, a sequence of events may be suggested, as follows.

(1) The atom A approaches the terminal atom B with such a velocity that when A is finally brought to rest relative to B, the internuclear distance $A—B$ is very short compared with the equilibrium distance in the molecule AB. This requires the existence of some attractive force to overcome the repulsion experienced by non-interacting particles in the systems to which the Maxwell–Boltzmann statistics and equipartition principles apply.

(2) The bond $B—C$ must be weak relative to the newly formed bond $A—B$, so that the dissociation of the intermediate complex $(ABCD) \rightarrow AB + CD$ can occur easily, and so that little of the impact of A on B will be transmitted through to the bond $C—D$.

(3) In consequence, the final products of the 'encounter' will be a molecule AB produced initially in a highly compressed state, that is, vibrationally hot, and a molecule CD, produced vibrationally cold. The greater the attraction between A and B, and the weaker the bond strength $B—C$, the greater will be the proportion of the energy of reaction appearing in the new bond $A—B$.

Examination of Table 1 shows that in all the reactions which yield vibrationally hot molecules, the conditions implicit in the above scheme are operative, that is, attraction between A and B and weakness in the bond $B—C$.

In the first two reactions, both the atoms and the reactant molecules are paramagnetic, so that the probability of electron spin coupling will result in an attractive potential field between the atom and the molecule. The ClO—O and NO—O bond-strengths are both moderate, being about 60 and 72 kcal./mole, respectively.

The most striking feature of the next four reactions is the fact that they all involve the ozone molecule: it would be surprising indeed if this were fortuitous. It is at once obvious that ozone satisfies the requirement of a weak $B—C$ bond, since the $O_2—O$ bond dissociation energy is only 24 kcal./mole. However, since the molecule is diamagnetic it is not immediately obvious that there will be an attraction between the approaching atom and the terminal oxygen atom. In order to overcome this difficulty, it is convenient to consider the ozone molecule from a somewhat inverted point of view, that is, not as a strongly bound molecule in a singlet state, but rather as a weakly bound complex of a triplet oxygen molecule and a triplet oxygen atom. Although the complete system will have singlet multiplicity, at large $O_2—O$ separations the terminal oxygen atom will assume in large measure the character of an unbound ^3P atom. This will be particularly favoured in ozone since the $O_2—O$ bond-strength is so small, and, in consequence, the $O_2—O$ vibrations have a large amplitude. Thus the formation of electron pair bonds between an approaching free atom and the terminal oxygen atom in ozone becomes a possibility; as in NO_2 and ClO_2, this possibility will result in an attractive potential field between the approaching atom and the molecule. The well-known addition of ozone to olefins yielding covalently bound ozonides provides confirmation of its ability to form electron pair bonds.

The production of vibrationally excited sodium iodide following a collision between an iodine atom and a sodium molecule in the gas phase would be especially favoured, since not only is the Na—Na bond-strength extremely weak (17·5 kcal./mole), but also the coulombic attraction between the halogen atom and the alkali metal would be very strong indeed. This is consistent with the observation that sodium iodide is produced possessing nearly all the energy liberated in the reaction[5].

In the last two reactions tabulated, no vibrationally excited species are produced[6,7]. Again, this is consistent with the general scheme proposed, since both Cl_2O and SO_2 are diamagnetic, and at the same time the SO—O and $Cl_2—O$ bond-strengths are large, being about 130 and 100 kcal./mole, respectively. (It will be necessary to break two Cl—O bonds in order to obtain the reaction $O + Cl_2O \rightarrow O_2 + Cl_2$, since in Cl_2O oxygen is the central atom.)

Summarizing, it is apparent that all the reactions tabulated can be understood in terms of the simple collisional model which has been proposed. The comparative rarity of reactions in which the products are vibrationally excited is consistent with the strict requirements necessary for such reactions. On the basis of the model, the reaction $O + ClCO \rightarrow ClO +$

CO should yield vibrationally excited ClO radicals, and experiments are being planned to determine whether or not vibrationally hot ClO is formed.

Electrical and Magnetic Properties of β-Carotene Triiodide

Charge–transfer complexes formed between iodine and condensed ring aromatic hydrocarbons have been studied in some detail recently, most extensively by Akamatu, Inokuchi, Matsunaga and their co-workers[1]. We should like here to point out that iodine also reacts with β-carotene, a non-aromatic hydrocarbon containing eleven conjugated double bonds, to form a compound exhibiting electrical and magnetic properties similar to those of iodine-aromatic charge–transfer complexes. The stoichiometric formula of this compound is $C_{40}H_{56}I_3$; that is, it contains three iodine atoms per β-carotene molecule.

This material was prepared first by Arnaud[2] and later by Willstätter and Mieg[3] in the course of their investigations of the structure of carotene. It is formed by adding crystalline iodine to a concentrated solution of β-carotene in benzene or carbon disulphide. The triiodide, which is precipitated immediately, is washed with diethyl ether and dried in vacuum. The resulting powder has the same physical appearance (red by reflexion, green by transmission) and melting point (137° C.) as reported by Arnaud[2]. Iodine analyses were made on two samples, independently prepared, giving 41·1 and 42·9 per cent iodine (cal.: 41·5 per cent).

Evidently, the triiodide can be prepared only in the way outlined above. If one mixes solutions of iodine and β-carotene, only a slow reaction occurs giving a substance of formula $C_{40}H_{56}I_2$, presumably an iodine addition compound[3].

The samples of $C_{40}H_{56}I_3$ we have prepared all exhibit a strong electron spin resonance absorption consisting of a single line of Gaussian shape with $\Delta H_{p\text{-}p} = 11{\cdot}4$ gauss and $g = 2{\cdot}003$. A comparison of the electron spin resonance intensity of a freshly prepared sample with that of Coppinger's radical[4] indicates a spin density of $7\text{–}15 \times 10^{18}$ cm.$^{-3}$, corresponding to 0·01–0·02 spins per molecule of $C_{40}H_{56}I_3$. The electron spin resonance intensity and line shape show no dependence on temperature from −170° C. to +30° C. The signal intensity decays with time with a half-life of several days for a sample exposed to air; the half-life is several weeks for a sample prepared and stored under nitrogen.

The d.c. electrical conductivity of a powder sample was measured in a high-resistance powder press in which the sample could be compressed until its conductivity no longer increased with further compression. The sample and cell were reassembled several times; the conductivity in no case differed by more than 10 per cent. Fig. 1 illustrates the variation of conductivity with temperature for a sample approximately 24 hr. old. A reasonable fit to these data is obtained using the expression $\sigma = \sigma_0 \exp(-E/kT)$, with $E = 0{\cdot}55 \pm 0{\cdot}5$ eV. and $\sigma\,(25°\,\text{C.}) = 5 \times 10^{-9}$ ohm^{-1} cm.$^{-1}$. All the samples measured exhibit the same value of the quantity E, whereas the quantity σ_0 was observed to vary considerably from sample to sample. The conductivity decays slowly with time in a manner similar to the decay of the electron spin resonance signal intensity.

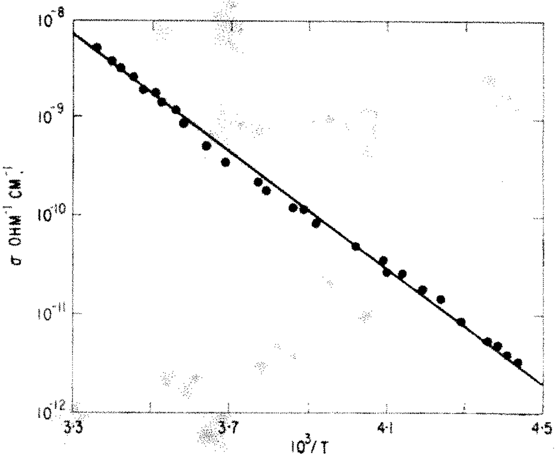

Fig. 1. Variation of electrical conductivity with temperature over the range $T = 225°$ K. to $T = 300°$ K.

Conductivity measurements on powder samples, such as we present here, certainly are open to serious criticism[5]. However, we believe that these measurements have sufficient qualitative significance to establish the complete dissimilarity between the dependence on temperature of the conductivity and that of the electron spin resonance signal intensity in $C_{40}H_{56}I_3$. This result is in marked contrast to that of Singer and Kommandeur for the pyrene–iodine complex[6]. Our observations can be interpreted in two ways: either (1) the electron spin resonance intensity is not a measure of the number of carriers involved in conduction, or (2) the electron spin resonance intensity is a measure of the number of carriers involved in conduction, and since the intensity is independent of temperature, the dependence of the conductivity on temperature arises entirely from the temperature dependence of the carrier mobility.

We have also investigated the visible and ultraviolet spectra of dilute solutions of iodine and β-carotene in chloroform. Intense new bands appear at 2920 and 3600 Å. From a preliminary study of the spectra as a function of solute concentrations, it appears that both bands arise from a chemical species formed in a fairly rapid, reversible reaction between iodine and β-carotene, and that this species is most probably $C_{40}H_{56}I_3$. Unfortunately, this work is complicated by poor stability of the solutions. The bands at 2920 and 3600 Å. disappear in a matter of hours due, presumably, to the competing reaction in which the addition product $C_{40}H_{56}I_2$ is formed.

Dr. Edel Wasserman of the Bell Telephone Laboratories has undertaken a determination of the crystal structure of $C_{40}H_{56}I_3$ by X-ray diffraction[7]. This should clarify considerably the nature of the chemical bonding involved and should determine whether this material can reasonably be described as a charge-transfer complex.

BIOCHEMISTRY

Action of a Bacterial Dextranase on Branched Dextrans

SEVERAL mould species[1,2] and strains of Bacteroides[3] have been shown to secrete dextranases which hydrolyse, to different degrees, dextrans of various branched structures. Although glucose, *iso*maltose and *iso*maltotriose[1–3] have been shown to be among the main products of the hydrolysis, no oligosaccharides containing the glucosidic branch linkages have so far been identified in the enzyme hydrolysates. Recently, several rumen strains of an organism, closely resembling *Lactobacillus bifidus*[4], were found to secrete a dextranase which hydrolysed an unbranched *Streptococcus bovis*[5] dextran to a mixture of *iso*malto-triose, -tetraose, -pentaose and -hexaose[6]. The enzyme also hydrolysed a dextran (produced by *Leuconostoc mesenteroides*, Birmingham strain) containing 12–15 per cent of α-1,3-branch links[7] to a mixture of tri- and higher saccharides, which were not examined further. We have now investigated the oligosaccharide mixture produced by the enzyme from this and other branched dextrans.

Solutions were prepared containing dextranase[6] (10 mgm.), purified[7] dextran (30 mgm.), and citrate buffer (0·2 *M*, *p*H 5·5, 5 ml.). A solution of the above composition, containing unbranched *S. bovis* dextran, was used as a control. The solutions were incubated under toluene at 37° C. for 36 hr., after which time there was no further increase in reducing sugars. The final digests were desalted with 'Biodeminrolite', concentrated under reduced pressure to a small volume, and analysed by paper chromatography using the ethyl acetate, pyridine, acetone, water solvent of Malpress and Hytton[8]. Reducing sugars were located with silver nitrate[9]. Intense spots, corresponding to *iso*malto-triose, -tetraose and -pentaose, were present on chromatograms of all the hydrolysed dextrans. In addition, chromatograms of the *Leuconostoc* branched dextran digest showed two minor reducing components moving just in front of *iso*malto-tetraose and -pentaose respectively. These chromatograms also revealed a mass of unresolvable reducing components, $R_G <$ *iso*maltopentaose, which was absent from the control digest. Portions of the two extra oligosaccharides were eluted and hydrolysed in *N* sulphuric acid for 4 hr. at 100° C. The hydrolysates contained a single component which was chromatographically identical to glucose.

Table 1. POSSIBLE OLIGOSACCHARIDES IN ADDITION TO *iso*MALTOTRIOSE— -PENTAOSE DETECTED IN DEXTRANASE–DEXTRAN DIGESTS

Dextran; organism and type of branch link	Fast-moving tetraose	Fast-moving pentaose	Saccharides of $R_G <$ *iso*maltopentaose
(1) *S. bovis*; unbranched (ref. 5)	absent	absent	*iso*malto-hexaose^{+++}, -heptaose^{++}
(2) *L. mesenteroides* (Birmingham); modified, 2 per cent α-1,3- (ref. 9)	trace	trace	*iso*malto-hexaose^{++}, -heptaose^{+}
(3) *L. mesenteroides* (Birmingham); 12–15 per cent α-1,3- (ref. 7)	++	+++	intense unresolved mixture $R_G <$ *iso*maltopentaose
(4) *L. mesenteroides* (N.R.R.L. *B*512); 5 per cent α-1,3- (ref. 10)	trace	trace	possible hexaose^{+++}, heptaose^{+++}, octaose^{++}
(5) *Betabacterium vermiforme*; 5 per cent α-1,3-, 5 per cent α-1,4- (ref. 11)	trace	trace	possible hexaose^{+++}, heptaose^{+++}, octaose^{++}
(6) *Acetobacter capsulatum*; 10 per cent α-1,4- (ref. 12)	absent	absent	possible hexaose^{+++}, heptaose^{+++}, octaose^{++}, nonaose^{+} and unresolved higher saccharides

Gradings allocated on the basis: trace, just visible; +, clearly visible; + + +, definite black spot. Under the conditions used *iso*maltotriose spot = + + + + + +.

The three main components in the digest have been shown, by movement in five solvent systems and reaction with four spray reagents, to be chromatographically identical with *iso*malto-triose, -tetraose and -pentaose, respectively. It seems likely, therefore, that the two extra saccharides contain, in addition to α-1,6-links, the α-1,3-branch links of the original dextran. Their absence from the control digests seems to rule out the possibility that they were formed by an enzymic transferase action on the *iso*maltodextrins produced in the digests. Attempts are now being made to elucidate the structure of these two sugars. As the dextranase has been shown to hydrolyse *iso*malto-heptaose and -octaose, the mass of higher saccharides present in the branched dextran digest probably also contains α-1,3-branch links which prevented their further hydrolysis. Two acid-degraded specimens of the branched *Leuconostoc* dextran, mol. wt. 300,000 and plasma grade, were also treated with dextranase. The same two extra saccharides were detected on chromatograms of the digests at possibly lower concentrations. The three *iso*maltodextrins and the unresolved mixture of $R_G <$ *iso*maltopentaose were also present.

Several other dextrans, the structures of which have been examined by chemical methods, were treated with the dextranase and the hydrolysates examined by paper chromatography. The results, with those already obtained, are listed in Table 1.

It appears that *L. bifidus* dextranase is unable to cleave branching links in dextrans. This is not surprising as the organism was cultured in a medium containing unbranched *S. bovis* dextran. The mixture of saccharides produced seems to depend not only on the type of branching, but also on the degree of branching; compare dextrans Nos. 3 and 4 in which there appears to be a definite difference in the composition of the saccharide mixture of $R_G <$ *iso*maltopentaose. Another dextran, produced by *L. mesenteroides* (N.R.R.L., *B*742) and containing 36 per cent of α-1,3- and α-1,4-links[11], was also treated with the enzyme. This dextran was not hydrolysed by the dextranase, a result which is in agreement with the markedly different serological properties reported[13] for a similarly branched dextran produced by another strain (N.R.R.L.-*B742-LR*) of this organism. The possibility that dextranases produced by *L. bifidus* and other organisms may be of help in establishing the structures of dextrans is being investigated further.

This work was carried out as part of a programme of research supported by the Department of Scientific and Industrial Research and directed by Prof. E. J. Bourne. Thanks are due to Dr. A. E. James, of Glaxo, Ltd. (Barnard Castle), for the gift of the samples of degraded *Leuconostoc* dextran.

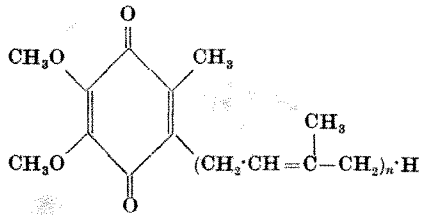
Ubiquinones and Ubichromenols in the Rat

UBIQUINONE, a naturally occurring quinone of considerable biological interest, was first isolated by Morton *et al.*[1], who found it in many kinds of animal tissue. Lester *et al.*[2] have shown that a series of such quinones exist, and have isolated, from different organisms, five compounds of general formula:



differing from each other by single isoprene units ($n = 10$, 9, 8, 7 and 6). Further studies[3] suggested that ubiquinone 50 ($n = 10$) was the normal quinone in higher mammals, but Rüegg *et al.*[4] have recently shown that rat liver contains ubiquinone 45 ($n = 9$).

By the use of analytical procedures described elsewhere[5], we have now found that the ubiquinone fraction of rat tissues may contain up to six substances. These are the isoprenologues, ubiquinones 50, 45, 40 and 35 and two other quinones, one of which has been tentatively identified as dihydroubiquinone 45 (side-chain reduced), whereas the second is an unsaturated substance of greater molecular weight than ubiquinone 50, and possessing a distinctive ultra-violet spectrum with sharp absorption peaks at 252·5, 259, 267·5 and 271·5 mμ.

The six substances do not usually occur together. Rather, two distinct patterns are found. One, in which only ubiquinones 45, 40 and 35 are present, has so far only been found in the tissues of older rats, more than 12 months of age. The second pattern, in which all or some of the other three compounds occur together with ubiquinone 45, is always observed in younger animals and sometimes in the older ones. In most of the 14 tissues so far studied, ubiquinone 45 is the predominant quinone. Although we do not yet understand the significance of the two quinone patterns, it seems that (at least in rats of our Norwegian hooded strain) they only vary in a quantitative manner from organ to organ. Thus we have never observed ubiquinone 50 in the same pattern as ubiquinone 40 in the tissues of our animals. There may, however, be strain differences, since in rats of another strain, we have seen an occasional mixed pattern containing five quinones (including the unidentified quinone referred to above). Our investigations of the quantitative relationships and the influence of dietary and other factors on these quinone patterns will be reported elsewhere.

The discrepancy between the melting points given by Lester *et al.*[2] for ubiquinones 50 and 45 (49·9° and 45·2°, respectively) and those given by Morton *et al.*[1] for specimens isolated from "different sources" is still unresolved, and it has been suggested[6] that the preparations of Morton *et al.* contained artefacts caused by replacement of methoxyl by ethoxyl groups during the preliminary purification with ethanolic alkali. However, in view of our present findings, it seems possible that, since Morton *et al.* used rat liver as one of their sources, their melting-point data may be sufficiently explained by the likelihood that they were dealing with mixtures.

The recent demonstration by Laidman *et al.*[7] that substance *SC* is a cyclic isomer of ubiquinone 50 (which they have called ubichromenol) suggests a biochemical relationship between the two compounds. We have now found that the mixture of ubiquinones in rat tissues is almost invariably accompanied by a similar mixture of ubichromenols, although—because of chromatographic and identification difficulties—it is not always possible to detect the completely corresponding series. So far, we have tentatively identified ubichromenols 50, 45, 40 and 35 and observed that these substances are only normally present if the preparation contains the corresponding isomeric quinone or mixture of quinones. Thus ubichromenol 50 is not found in preparations that contain the 45–40–35 pattern of quinones. Ubichromenol 45 is usually the main chromenol present, but the patterns can be varied under suitable experimental conditions (these are at present under study).

The ubiquinones were identified by their spectra and paper chromatographic behaviour in comparison with known markers. The ubichromenols and dihydroubiquinone 45 were characterized by their spectra and also their chromatographic behaviour, followed by calculation of R_M values from a series of parameters obtained from model compounds. Dihydroubiquinone 45 was also converted to perhydroubiquinone 45 for identification purposes.

These findings suggest that ubiquinones and ubichromenols may be synthetically connected in biological systems, perhaps through intermediary dihydroquinones. Further work (to be published) confirms this concept and has demonstrated that the synthesis of ubiquinone is, contrary to the findings of other workers[8,9], significantly affected by vitamin E.

Identification of Isomeric Chondroitin Sulphates

CHONDROITIN SULPHATE occurs in three isomeric forms, *A*, *B* and *C* (see review by Hoffman *et al.*[1]). Mathews[2] has recently found the *pK* values of the carboxyl groups of chondroitin sulphate *A* and chondroitin sulphate *B* to be 3·1 and 3·5–3·6 respectively. In addition the *A* and *B* isomers have very similar electrophoretic mobilities in free solution at *p*H values of 2, 3 and 7. Results for chondroitin sulphate *C* were not given.

This communication describes the results of experiments on the ionophoretic behaviour of the three compounds on paper. Using buffers of varying compositions and *p*H (*p*H 2·3, 5·5, 6·0, 9·0 and 9·5), chondroitin sulphate *C* was found to have a consistently lower mobility of 0·9 times that of either *A* or *B* isomeric forms. The latter was found to have the same mobilities in all the buffers used. Analyses of the chondroitin sulphate *A* and chondroitin sulphate *C* used in these experiments have been reported previously; they contained negligible amounts of protein (0·5 per cent)[3]. Additional preparations of the *A* form were made from bovine nasal septum and were found to have identical ionophoretic mobilities to that isolated from bovine trachea. The *B* form was kindly supplied by Dr. A. Dorfman. When mixtures of the isomers were subjected to ionophoresis, resolution could not be obtained (Fig. 1). Extension of the path of migration from 20 cm. to 28 cm. did not facilitate the separation of mixtures. Depolymerization of chondroitin sulphate *C* by a very brief treatment with testicular hyaluronidase[3] did not alter its mobility relative to chondroitin sulphate *A*. Similar results were obtained when either the sodium or the calcium salts of the *A* and *C* isomers were used. It seems likely that the difference in ionophoretic mobility between the *A* and *C* isomers is related to the position and conformation of the sulphate group. This group is axial in *A* and equatorial in *C*[4].

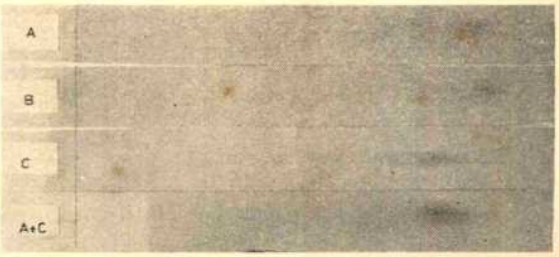

Fig. 1. Paper ionophoresis of chondroitin sulphate *A* (*A*), chondroitin sulphate *B* (*B*), chondroitin sulphate *C* (*C*) and a mixture of isomers *A* and *C* in 0·05 *M* sodium phosphate, *p*H 6·0, at 9·7 V./cm. for 4·5 hr. 2·5 μl. of a 3 per cent w/v solution of each isomer applied to dry paper (Schleicher and Schull 2043*B*). Stained with toluidine blue

It has been shown previously that forms *A* and *C* can be synthesized by a cell-free extract of embryonic chick cartilage[3]. The extract is relatively saturated with chondroitin sulphate *A* and little effect on the incorporation of (sulphur-35) sulphate into chondroitin sulphate resulted when the *A* isomer was added to this extract and the mixture incubated with adenosine triphosphate and (sulphur-35) sulphate. Addition of the *C* isomer, however, caused a marked stimulation of incorporation of sulphate into chondroitin sulphate. A type-specific priming mechanism was evident. By removal of the normal content of acid mucopolysaccharides from the chick cartilage extract by treatment with protamine, the ability to synthesize chondroitin sulphate was lost but was restored by addition of the *A* or *C* forms. Chondroitin sulphate *B*, which does not occur in cartilage[5], could not replace the *A* or *C* isomers but did show some priming power which was perhaps due to small amounts of the *A* or *C* isomers possibly contained in the preparation. Addition of *A* or *C* isomers to the enzyme system treated with protamine should result in synthesis of the corresponding isomer if the type-specific mechanism of priming action is correct[3]. Since the pure isomers *A* and *C* of chondroitin sulphate have different ionophoretic mobilities, it is possible to test this theory. Results of such an experiment are shown in Fig. 2. The (sulphur-35) chond-

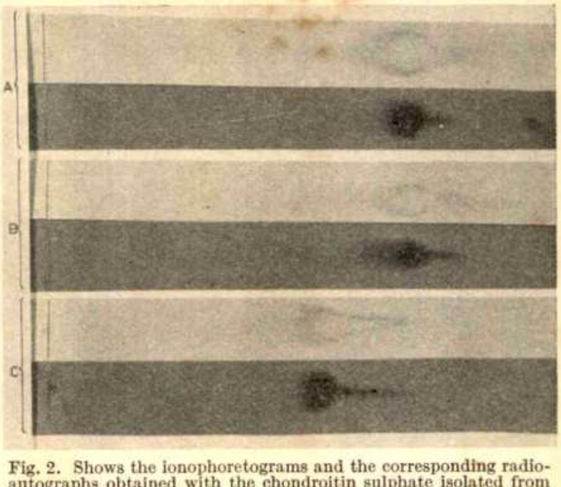

Fig. 2. Shows the ionophoretograms and the corresponding radioautographs obtained with the chondroitin sulphate isolated from normal incubations (ref. 3) in the presence of 10 μc. (sulphur-35) sodium sulphate, 0·4 ml. of protamine-treated chick cartilage extract and 2·1 mgm. of the sodium salts of each chondroitin sulphate isomer. After incubation, the tubes were heated at 100° for 1 min., cooled, centrifuged and the chondroitin sulphate isolated by precipitation with 'Cetavlon' in the presence of sodium sulphate. Each sample was dissolved in 0·5 ml. of 10 per cent w/v sodium chloride and the free chondroitin sulphate precipitated by the addition of alcohol (1·5 vol.). The precipitate was dissolved in 0·1 ml. of water and 10 μl. applied to paper for ionophoresis in 0·025 *M* citrate buffer, *p*H 5·5, at 9·7 V./cm. for 4 hr. The metachromatic zones are more diffuse as compared with Fig. 1, due to the larger amounts of material applied to the paper

roitin sulphate isomer synthesized by the enzyme extract is demonstrated by the radioautographs and these zones correspond to the isomer added to, and isolated from, the incubation mixture as shown by the metachromatic zones. This is conclusive proof for the specificity of the enzyme–substrate relationship.

One consequence of these results is applicable to the study of the types of chondroitin sulphates being actively formed by particular tissues. Rather than attempting to isolate, fractionate and identify the chondroitin sulphates from the relatively large amount of tissue normally required by this procedure, it should be possible to prepare an enzyme extract from small amounts of such tissue, free it of its constituent acid mucopolysaccharides and determine which type or types of chondroitin sulphate are synthesized by observing the effects of addition of the three isomers. Alternatively, to determine whether isomer *A* and/or *C* is synthesized, a crude preparation of the constituent acid mucopolysaccharides can be isolated from the tissue in question and tested with the embryonic chick cartilage extract in the presence and absence of excess amounts of the *A* and *C* isomers. It is intended to apply this type of investigation to the study of stromal elements associated with certain tumours.

Biosynthesis of Colchicine

Of several proposals[1-4] concerning the biogenesis of the alkaloid colchicine (5 ; $R_1 = R_2 =$ Me), only that of Wenkert[4] involves the intervention of an intact tropolone ring prior to formation of ring *B*.

I now wish to suggest that a radical pairing reaction (4→5) involving one-electron oxidation of a tropolone ring might well represent the crucial stage in the elaboration of the tricyclic system. In support of this view I may mention that radical substitution has been observed in the case of diazotized 5-aminotropolone[5]. Also, the occurrence of partially methylated alkaloids[6,7] in *Colchicum* species (for example, 5 ; $R_1 =$ H ; $R_2 =$ Me) and the unlikely intervention of the $C_6{-}C_1 \rightarrow C_7$ change at aromatic level[4,8] would seem to be in accord with the present proposal.

It may also be conceivable that the genesis of purpurogallin from pyrogallol[3] involves a radical-pairing reaction[9]. The conversion of the former compound to the acid (2) takes place under biochemically acceptable conditions[10]. The biosynthesis of (4) has many possibilities of which only one is suggested herein. Experimental confirmation of this concept is being sought.

Swelling of Fresh and Aged Liver Mitochondria as affected by Succinate, Adenine Nucleotides and Thyroxine

It has been observed previously[1] that isolated mitochondria from primary and transplanted hepatocellular hepatomas, in contrast to their normal counterparts from liver, do not swell to any marked extent in the presence of thyroxine. The increasing evidence[2-4] that both the spontaneous and thyroxine-induced swelling of liver mitochondria is actually dependent upon respiration (that is, when no oxidizable substrate is added, upon endogenous substrate and co-enzymes) has led us to re-examine the effect of thyroxine on the swelling of the tumour particles now incubated in the presence of succinate.

Previous investigators[2,5] reported that several oxidizable substrates, including succinate, markedly and instantaneously accelerated the swelling of fresh liver mitochondria from the rat. However, in our control experiments carried out with freshly isolated (0·3 *M* sucrose) mouse and rat liver mitochondria under similar conditions[2,3], the latter effect, as far as succinate (5×10^{-4} *M*) was concerned, has never been observed. On the contrary, in the suspensions (0·3 *M* sucrose containing 0·02 *M tris* (2-amino-2-hydroxymethylpropane-1 : 3-diol chloride), *p*H 7·4, 22 ± 1° C.) in which spontaneous swelling occurred, succinate prevented the latter completely during at least 40 min. Hereafter the protection changed into a sudden acceleration of the swelling so that in a relatively short time (approximately 20 min.) a decrease of 50 or more per cent in the $O.D._{520}$ ($O.D._{520}$, optical density at 520 mμ) took place. In addition to recording the decreases in $O.D._{520}$ as a measure of swelling, mitochondrial samples were examined under the phase contrast microscope and the fall in $O.D._{520}$ was always found to be accompanied by the typical signs of swelling. Obviously, then, in our hands the swelling of the liver mitochondria in the presence of succinate was conditioned by some 'change' occurring during the incubation at room temperature.

Since direct and indirect evidence[6-8] shows that phosphorylating or mitochondria containing adenosine triphosphate do not swell, it was thought likely, in view of the absence of magnesium and adenine nucleotides from the medium, that the above 'change' was related to the abolition (of one of the intermediate reactions[9]) of oxidative phosphorylation, perhaps as a result of the loss of endogenous adenine nucleotides. If this consideration contained an element of truth, the alleged change might be accelerated by subjecting the mitochondria to ageing[10] and, as long as it was not irreversible, counteracted by the addition of adenine nucleotides in a sufficiently low concentration (10^{-5} *M*) as to make any chelating effect of the latter unlikely. Keeping the mitochondria during 3 hr. at 0° C. in 0·3 *M* sucrose reduced the time of protection afforded by succinate against the spontaneous swelling on subsequent incubation in the 0·3 *M* sucrose–0·02 *M tris* medium to about half the value found for the fresh particles. The outburst of swelling which then set in, and also the later one occurring in the fresh preparations, could be prevented (or at least markedly delayed) by the simultaneous presence of adenosine monophosphate and adenosine triphosphate (10^{-5} *M* each). When, following the 3 hr. at 0° C., the mitochondria had in addition been held in 0·3 *M* sucrose at 37° C. during 10–15 min., succinate momentarily accelerated the swelling and the adenine nucleotides showed scarcely, if any, retarding effect on the latter process. The effects of succinate under the various experimental conditions were always abolished by malonate (10^{-3} *M*), pointing to the paramount role of succinate oxidation in the two kinds of effects, that is, the protection against and the acceleration of swelling.

If, as has been suggested[11,12], the induction of swelling by thyroxine *in vitro* represents an acceleration of a process which the particles are already inherently capable of undergoing spontaneously, it must be possible to counteract the thyroxine-induced swelling by addition of succinate and the adenine nucleotides. The onset of the swelling produced by thyroxine (3×10^{-5} *M*) in fresh mitochondria was indeed significantly delayed (10–15 min.) by succinate and still more by succinate and adenosine monophosphate and adenosine triphosphate (at least another 10 min.). Malonate, again, prevented this effect of succinate. The retardation of the onset of the thyroxine-induced swelling produced by succinate alone or together with the nucleotides was somewhat less pronounced in the suspensions which had been previously kept at 0° C. during 3 hr., but was completely missing in those preparations which had received another incubation at 37° C. during 10–15 min. In fact, the swelling produced by thyroxine in the latter preparations was frequently (not always) largely dependent upon the presence of succinate, which might have been due to the limiting amount of endogenous substrate still present[3]. By contrast, in the fresh and mildly aged mitochondria the extent of swelling ultimately reached in the presence of thyroxine (50 per cent decrease in $O.D._{520}$) was independent of the additions made. In view of the present observations it is of interest that Kaufman and Kaplan[13] have recently reported that, in contrast to the finding of previous investigators[3,14], succinate also inhibited the phosphate-induced swelling of the mitochondria.

The rats and mice used in the above experiments were fed *ad libitum* with the standard laboratory diet. Starvation during 24 hr. prior to the preparation of the mitochondria did not change the results. Rats which had been fed polished rice during several months yielded liver mitochondria of which the onset of swelling on incubation with thyroxine was very markedly retarded by succinate and by succinate plus the nucleotides, sometimes even for 40 and 60 min., respectively.

On account of all criteria set out above, freshly isolated liver mitochondria from rats, which had received an intravenous injection of a hepatoxic dose of the hepatocarcinogen dimethylnitrosamine (100 mgm./kgm. body-weight) 20 hr. earlier, have been found to resemble closely liver mitochondria from normal rats previously aged during 3 hr. at 0° C. followed by 15 min. at 37° C.

In view of the 'change' which has been postulated above as conditioning the swelling of mitochondria, it is of interest that the liver mitochondria from the dimethylnitrosamine-treated animals showed a partly uncoupled oxidative phosphorylation and an increase in adenosine triphosphatase activity, the manifestation of which was for the greater part dependent on magnesium. In the swelling experiments with normal liver mitochondria (fresh or after 3 hr. at 0° C.) several cases have been encountered in which adenosine monophosphate and adenosine triphosphate added in the absence of oxidizable substrate had scarcely, if any, effect on the patterns of the spontaneous and thyroxine-induced swelling (especially in suspensions containing mitochondria which had been kept at 0° C. during 3 hr.), or a smaller effect than when added in conjunction with succinate.

It may therefore be concluded that the process which prevented the entry of water into the mitochondria was dependent upon added oxidizable substrate and adenine nucleotides (as distinct from the situation in which a high concentration of adenosine triphosphate added singly may prevent or reverse swelling[9,14]), thus pointing to a role of oxidative phosphorylation[7,8] in the maintenance of mitochondrial structure. As regards the nature of the substrate, it appeared that succinate was (much) more effective than glutamate, α-ketoglutarate, pyruvate or β-hydroxybutyrate in counteracting the spontaneous and thyroxine-induced swelling.

Glutamate may, in fact, cause an immediate swelling of the fresh particles, especially when diphosphopyridine nucleotide was also present; diphosphopyridine nucleotide ($3 \times 10^{-4} M$) alone was sometimes similarly active[4].

The difference in effect of the various substrates might have been due to the fact that the phosphorylation accompanying succinate oxidation, or an intermediate reaction thereof, is especially involved in the contraction of the mitochondrial membranes[7] and/or to the fact that the corresponding processes of the diphosphopyridine nucleotide-linked oxidations are less stable[15], so that in the latter case the postulated 'change' may occur more readily under the conditions of the present experiments, which are certainly unfavourable to the maintenance of these integrated systems. It appears that the 'change' sets the trigger for swelling, while the actual swelling is dependent upon the presence of substrate, that is, on electron transport in (part of) the respiratory chain[2,3].

Presence of Protein in Some Serum Filtrates

In the determination of creatinine in plasma or serum the method of preparation of protein-free filtrates is known[1] to influence the total chromogen content of such fluids. Moreover, varying amounts of non-creatinine chromogen in such filtrates are known[2] to be partly responsible for differences in the total chromogen content.

It is generally assumed that a 1 : 5 'neutral' tungstic acid filtrate ($p\text{H} > 2{\cdot}5$), prepared as follows: 6 ml. distilled water, 2 ml. serum, 1 ml. 10 per cent sodium tungstate, 1 ml. $0{\cdot}66\ N$ sulphuric acid, and filtered through a Whatman No. 1 filter paper, is totally free of protein. Yet, it is well known that the precipitation of proteins by tungstic acid and other 'protein precipitants' consists of a series of changes in the protein molecule, which may, under certain conditions, be reversible. For it often happens that more than one denatured protein is formed by the action of these protein precipitants on a solution containing different amounts of albumins and globulins. Moreover, the isoelectric points of these proteins are different, so that a certain proportion of the metaprotein so formed may remain in solution at any given reaction. Further, these changes often consist in the opening up and extension of the highly organized coiled polypeptide chains of the native proteins which effect their viscosity, particle-size and solubility, etc.

Thus, a 'neutral' tungstate filtrate contains a small amount of protein (3·08 mgm./100 ml. serum) which can be precipitated by 5 per cent phosphotungstic acid in $2\ N$ hydrochloric acid (1 ml. to 5 ml. filtrate). A 1 : 10 tungstate filtrate, prepared as follows: 7 ml. distilled water, 1 ml. serum, 1 ml. 10 per cent sodium tungstate and 1 ml. $0{\cdot}66\ N$ sulphuric acid, contains no such detectable protein. It is evident, therefore, that a 1 : 5 'neutral' filtrate is not entirely 'protein-free' but contains some material which has escaped total precipitation or has been held in solution under the conditions of precipitation. Further, it is possible that other low molecular weight carbohydrate-containing proteins, particularly the mucopolysaccharides, may also be present in plasma or serum filtrates, as some of the acid mucopolysaccharides have a very acid isoelectric point.

The protein precipitated by phosphotungstic acid has a concentration of 0·08 mgm./100 ml. serum (in terms of creatinine) in normal pooled sera. Moreover, since protein is 'chromogenic' to alkaline picrate solution, it is possible that some filtrates may contain small amounts of protein which may be related to the so-called 'interfering material' (non-creatinine chromogen) in the determination of creatinine by the Jaffé reaction in biological fluids. For this figure is in fairly good agreement with that found by Owen, Iggo, Scandrett and Stewart[3] using the *NC*-creatinine destroying bacteria of Miller and Dubos[4] for a 'neutral' tungstate filtrate (1 : 5). Further, Lloyd's reagent, which is used to remove the 'interfering material' from a serum filtrate[3], is also widely used for removing proteins at a $p\text{H}\ 2{\cdot}0$–$3{\cdot}0$ from protein-containing solutions.

Thus, it should be remembered that the various protein precipitants differ in their ability to produce a plasma or serum filtrate which is completely free of protein, and of low molecular weight protein fragments (proteoses and peptones, etc.) which can react and interfere with the Jaffé reaction.

PHYSIOLOGY

Endocrine Control of Sexual Reproduction in *Opalina ranarum* Parasitic in *Rana temporaria*

It is well known that opalinids parasitizing the recta of Amphibia multiply asexually by binary fission during most of the year. During the breeding season, however, the reproductive pattern changes to a sexual one, the preliminary stages of which are marked by an increase in the multiplication-rate and the production of small forms and minute individuals. The latter eventually encyst and are passed out with the fæces of the frog. If ingested by tadpoles, they excyst, form micro- and macro-gametes, and the resulting zygotes give rise to the multinucleated opalinids in the newly metamorphosed frogs.

It has long been suspected that the stimulus for inducing the change in the reproductive pattern of the opalinids was related to the endocrine behaviour of the host. Bieniarz[1] found that when male *Rana esculenta* were given injections of human pregnancy urine, the opalinids changed to a sexual pattern of reproduction resulting in the production of cysts. He suggested that the change might be initiated by the human chorionic gonadotrophin present. Cehovic[2] injected *R. esculenta* and *R. temporaria* with pregnancy urine, chorionic gonadotrophin or frog pituitaries, and obtained cyst formation. He concluded that the correlation between host and parasite life-cycles was due to pituitary activity and probably due to the production of gonadotrophin.

We have recently carried out a series of experiments on normal, hypophysectomized and gonadectomized *R. temporaria* with the following results.

(*a*) Injection of œstrone or gonadotrophic substances (concentrated or untreated pregnancy urine, chorionic gonadotrophin, serum gonadotrophin, suspension of frog hypophyses) to male and female frogs induced the sexual reproduction pattern of development in the opalinids—as evidenced by cyst production—but only in the period just prior to the breeding season (that is, during November–February in Europe) and not at other times of the year.

(*b*) Testosterone propionate and adrenaline injected into male and female frogs induced the sexual cycle of reproduction in the parasites during any time of the year.

(*c*) In gonadectomized animals, only injections of testosterone propionate were effective in inducing the sexual reproductive cycle in the parasites ; adrenalin was ineffective.

(*d*) *In vitro*, gonadotrophic hormones gave negative results in all cases ; but some positive results were obtained with untreated pregnancy urine. Some cultures treated with œstrone or hydrosoluble testis extract produced dividing stages and small forms, but cysts were never produced.

(*e*) In frogs prevented from copulating, the sexual reproductive cycle of the opalinids occurred in female frogs 77 days later than those which had copulated, and in the males, 82 days later.

These results clearly suggest that the induction of a sexual reproductive pattern in the opalinids is related, not to the levels of gonadotrophic hormones, but to the levels of gonadal hormones present in the host. In the male frog, the evidence shows that testosterone is implicated. In the female frog, in which the origin and nature of the gonadal hormone are obscure[3], the situation is not clear, for œstrone has been found only to induce cyst formation during the period just prior to the breeding season.

There is no evidence, as yet, to indicate whether the gonadal hormones exert their effect on these Protozoa directly or whether it is their breakdown products which are involved, or whether either of these exert their effect indirectly through some other aspect of the host's metabolism.

The effects of adrenalin injections in Amphibia are complex[4,5], and its action in inducing sexual reproduction in opalinids during any time of the year cannot be simply explained at the present phase of this work. The fact that it failed to induce cyst formation in gonadectomized frogs suggests that its action in some way induces the release of sex hormones, even when, in the male outside the breeding season, interstitial cells are absent from the testes.

Just prior to the breeding season, keeping the frogs at 8–12° C. induced cyst formation. That this result is attributable to the induction of early sexual maturity in the host and the subsequent release of the gonadal hormones may be shown by the fact that, during the summer, maintaining frogs at 20° C. failed to induce cyst formation, although injections of testosterone propionate induced the sexual cycle in the Protozoa, as at other times of the year.

Dr. Elspeth McConnachie[6] has kindly sent us the text of manuscript (in the press) in which she describes the induction of cyst production in *Opalina* by injection of frogs with chorionic gonadotrophin and frog pituitary extract. Although no experiments were carried out with the gonadal hormones, she concludes on theoretical grounds that the factors provoking encystation are probably the gonadal hormones.

Dipeptidase Activity of Brain

Available knowledge on the dipeptidase activity of brain is limited to the enzymatic hydrolysis of DL-alanyl-glycine[1-3]. Detailed studies by Pope *et al.* have dealt with the intralaminar distribution of dipeptidase activity towards DL-alanyl-glycine in the cerebral cortex of rat[1,2] and man[3]. Our own studies on proteolytic activity of brain led to a systematic inquiry into the existence of any selective or preferential dipeptidase activity of brain towards any particular dipeptidase structure. The present preliminary report deals with the systematic quantitative differences observed in the hydrolysis of the series of N-glycyl-dipeptides by mouse brain.

Freshly removed brains of adult Swiss albino mice were frozen on a glass slide placed on dry-ice, and immediately trimmed with a razor to remove the olfactory pole and the occipital poles (at the superior collicular level) to yield a standard-size block which was then cut into frontal sections of 75μ thickness on a freezing-microtome. Alternate sections were collected for total dry weight. Sections were immediately transferred to a chilled weighing-bottle containing 30 per cent glycerol in 4 per cent phosphate buffer at *p*H 6·97, and extracted overnight at 2° C. with occasional gentle stirring. This extraction procedure, similar to that used by Pope *et al.*[3], yielded a viscous, clear solution after centrifugation and filtration through sintered-glass micro-filters. To 50 μl. of extract in micro test-tubes 50 μl. of peptide solution (1·25–5·0 μmoles in 0·003 *N* sodium hydroxide) was added. After mixing by 'buzzing' on the shaft of a high-speed micro-motor, the tubes were incubated at 34° C. for 2 hr. together with separate tubes containing the same concentrations of the different peptides with only glycerol-phosphate buffer. After the incubation period, all tubes were chilled, 50 μl. of neutralized (phenolphthalein) 37 per cent formaldehyde and 4 μl. of 0·1 per cent phenolphthalein in 50 per cent ethanol were added to each tube. The formol titration was carried out against 0·1 *N* sodium hydroxide in a titration apparatus similar to that described by Linderstrøm-Lang and Holter[4]. The peptide and tissue blanks were subtracted from the enzyme-test values. The results are expressed in Fig. 1 and Table 1. The hydrolysis curve for DL-alanyl-glycine under the same conditions is presented for comparison in Fig. 1. Our observations indicate that the presence of a lipophilic aliphatic or aromatic side-chain is essential for dipeptidase activity in this category of dipeptides. Thus diglycine shows minimal splitting while all other glycyl-L-amino-acid dipeptides are maximally split. In keeping with the systematic difference, glycyl-γ-aminobutyric acid showed no splitting (Fig. 1), while the enzymatic hydrolysis of the glycyl-DL-α-aminobutyric acid was of the same order as the other dipeptides with a C-terminal DL-aliphatic or aromatic α-amino-acid residue. Similarly, glycyl-L-proline showed minimal hydrolysis under these conditions.

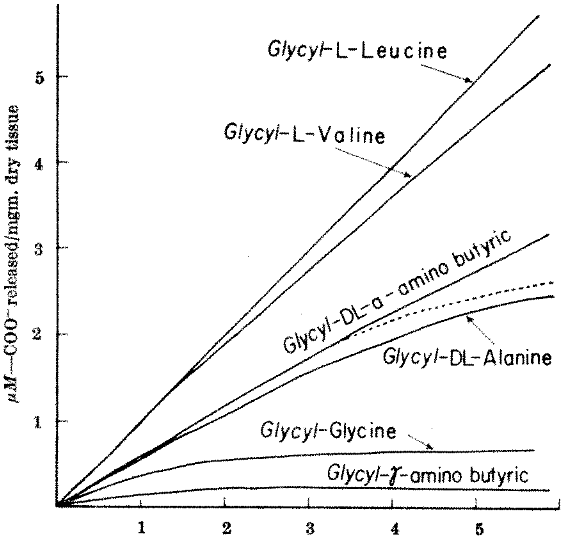

Fig. 1. Differences in peptidase activity of mouse brain dependent on presence of aliphatic side-chain of N-glycyl-dipeptides. The hydrolysis curve of DL-alanyl glycine at different peptide concentrations (dotted line merging with curve for glycyl-DL-α-aminobutyric acid) is included for comparison

Table 1

μM Peptide added/mgm. dry weight of brain	*μM*—COO⁻ released/mgm. dry weight of brain		
	1·5	2·5	5·0
Glycyl-glycine	0·50	0·55	0·72
Glycyl-L-alanine	1·45	2·40	4·47
Glycyl-L-valine	1·48	2·32	4·50
Glycyl-L-*iso*leucine	1·30	2·19	4·32
Glycyl-L-leucine	1·50	2·50	4·95
Glycyl-L-tyrosine	1·50	2·30	4·32*
Glycyl-L-phenylalanine	1·42	2·40	4·82
Glycyl-DL-alanine	0·82	1·34	2·30
Glycyl-DL-α-aminobutyric	0·90	1·45	2·78
Glycyl-DL-valine	1·04	1·60	2·73
Glycyl-DL-phenylalanine	0·80	1·26	2·20
Glycyl-L-proline†	0·40	0·40	0·40

* At this concentration the enzymatically released L-tyrosine precipitates out but redissolves during the formol titration.

† L-Proline in free form gives only 50 per cent of expected molar value in formol titration.

To our knowledge the existence of such structural requirements in the substrate was unsuspected for brain dipeptidase activity.

The same quantitative differences were observed when freeze-dried sections of mouse brain were extracted with 30 per cent glycerol in phosphate buffer, as well as when the peptides were incubated in the presence of fresh brain tissue slices in the glycerol-phosphate buffer solution without centrifuging off the slices to obtain a clear extract. In each instance the hydrolytic cleavage of each dipeptide, or lack of splitting, into component amino-acids was confirmed by paper chromatography. Incubation at 37° C. gave results identical with results of experiments carried out at 34° C.

Studies on a wide spectrum of related di- and tripeptides will be published in detail elsewhere.

Methane Exhalation in Sheep

IN view of the statements by Brody[1], Ritzman and Benedict[2], and Blaxter[3] to the effect that the ruminant exhales methane, it was deemed necessary to investigate the amount of methane which might be accumulated in the oxygen spirometer during indirect calorimetry experiments with sheep on full rations.

Appropriate arrangements were therefore made for gas analyses to be carried out by the Dominion Physical Laboratory at Wellington. On March 3, 1957, seven animals maintained on hay, crushed oats, and peas were chosen at random and each in turn was attached to the oxygen spirometer in the normal manner until it had exhausted one half the reservoir capacity—a period of about 10 min. The gas remaining in the spirometer was then collected and analysed. The results of the analysis of these samples are presented in Table 1.

Table 1. RESULTS OF ANALYSES OF GAS SAMPLES DRAWN AFTER THE SHEEP HAD EXHAUSTED HALF THE RESERVOIR CAPACITY OF A CLOSED CIRCUIT OXYGEN SPIROMETER*

Sheep No.	7	8	10	20	2	5	*X*
Methane	0·30%	0·05%	0·15%	0·20%	0·15%	0·15%	0·05%
Hydrogen	(0·02% or less)		(not found)				

* Hydrogen was included by the Dominion Physical Laboratory and is presented here for general interest.

There was no possible way in which the methane could have entered the spirometer other than from the lungs of the sheep. However, in view of the fact that in tracheotomized sheep some of the eructated gases flow back down the trachea—this was believed to be an original observation—the presence of traces of methane in the pulmonary system may have been due to residues from previous eructations. As the spirometer graphs used cannot be ruled to a greater accuracy than 0·05 l., a possible volume error of at the most 3 ml. of methane per 5 min. is considered to be low enough to be ignored in these experiments.

This work was supported by the Research Committee of the University of New Zealand. Particular thanks are due to the Director of the Dominion Physical Laboratory, Wellington, for offering the necessary laboratory staff and facilities.

Erythropoietine Production in the Dog

AN erythropoiesis-stimulating factor has been reported present in the plasma of numerous animals including the dog[1]. The dog, although readily available and a convenient source of relatively large volumes of plasma, has been utilized sparingly[2]. The present study was made in order that the hæmopoietic factor might be determined in the dog following exposure of the animal to various experimental procedures which are known to affect production of the factor in other species.

Five normal adult mongrel female dogs were placed in each of the following donor groups and subjected to the procedure indicated: group 1, untreated, healthy animals used as controls; group 2, hæmorrhage, 20 ml./kgm./day for 4 days; group 3, phenylhydrazine hydrochloride, 2·5 per cent, adjusted to *p*H 7·0, administered subcutaneously, 7·5 mgm./kgm./day, until the hæmoglobin concentration declined to 3·5–5·0 gm./100 ml.; group 4, the dog maintained in a closed chamber, in which the gases were mixed by a fan, with carbon dioxide being absorbed by soda lime. A mixture of 9 per cent oxygen–91 per cent nitrogen was admitted at a rate of 6 litres/min. for 24 hr.

At the end of the experimental period, each animal was bled, and 'protein-free' plasma prepared by the methods of Borsook[3], and Gordon[4]. This plasma preparation, pooled from each group, was injected intraperitoneally, in doses of 1·0 ml./100 gm./day, for 7–9 days into 200-gm. female Sprague–Dawley rats the hæmatological values of which had been determined. Terminally blood was removed by cardiac puncture from the 20 rats in each recipient group for determination of hæmoglobin, hæmatocrit, erythrocyte and reticulocyte values. The results in Table 1 indicate that the plasma from all donor groups, excepting that of the control animals, produced erythropoietic stimulation in the recipients. Additionally, the plasma of the phenylhydrazine-treated group stimulated erythrocyte production. In no case was reticulocyte percentage increased. The dog, like other animals, responds to appropriate stimuli by increased production of the erythropoietic-stimulating factor.

Table 1. EFFECT OF 'PROTEIN-FREE' PLASMA OF DOG ON RED CELL VALUES IN RATS

(Mean ± *S.E.*)	Hæmoglobin (gm./100 ml.)	Hæmatocrit (per cent)	Red blood count (mill./c.mm.)	Retics. (per cent)
Donors: (1) Control, normal dogs				
Rats: Before	14·9±0·15	45·0±0·30	8·4±0·26	1·1±0·17
After	14·6±0·18	44·4±0·18	8·7±0·13	1·3±0·21
(2) Hæmorrhaged dogs				
Rats: Before	13·8±0·19	40·8±0·88	7·8±0·23	2·2±0·21
After	14·9±0·16*	45·1±0·46*	7·9±0·14	1·7±0·19
(3) Phenylhydrazine-treated dogs				
Rats: Before	14·5±0·19	44·0±0·63	8·1±0·23	1·5±0·27
After	15·7±0·15*	47·3±0·35*	9·5±0·23*	1·4±0·18
(4) Hypoxic dogs				
Rats: Before	13·5±0·17	41·5±0·51	8·0±0·19	2·3±0·21

Ackee Toxin: a Riboflavin Antimetabolite?

THERE has occurred in Jamaica an illness known as 'vomiting sickness', characterized by vomiting, coma and death, which has been attributed to a toxin present in the ackee (*Blighia sapida*)[1-3]. In the course of routine assay for the protein values of human diets, a Jamaican meal containing this fruit was prepared, fed to rats, and the animals lost 26 per cent of their initial body-weight in 10 days. On a dry-weight basis, the meal contained 39 per cent green banana, 26 per cent salted cod-fish, 9 per cent coco-nut oil, 6 per cent salted pork fat, and 20 per cent ackee. Despite the high total protein content (17 per cent) of this mixture, it has a net dietary-protein value[4] of zero.

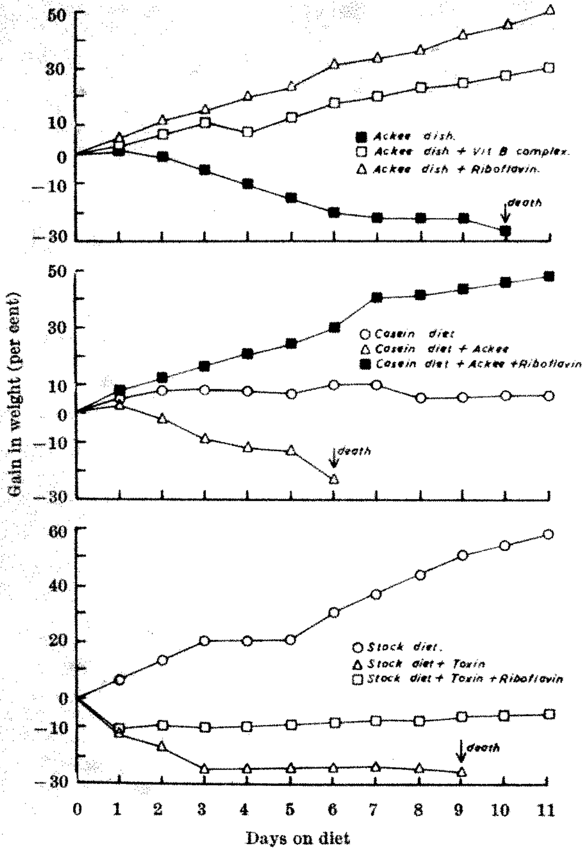

Fig. 1

By feeding each of the components of the meal separately in diets adequate in all nutrients, all were found to be innocuous, and the losses in weight on the complete meal were only prevented by supplementation with B vitamins, or more particularly with riboflavin (see Fig. 1). However, it is evident that simple riboflavin deficiency would not result in such an immediate and severe loss of weight[5] and, furthermore, analysis showed the diet to contain 0·28 mgm. riboflavin per 100 gm., which would supply the daily requirement for the rat[6]. This suggests that the meal contained an antimetabolite of riboflavin.

In another experiment the ackee was added to a synthetic, low-vitamin diet and was shown to produce a severe depression in growth-rate compared with a control. The addition of B-vitamins overcame both the adverse effect of the ackee and the low vitamin content of the diet: this is in agreement with the finding described above, where the toxic effects of the fruit could not be demonstrated with a diet containing 1 mgm. riboflavin per 100 gm.

Feng and Kean[7] have reported a protective action of protein to rats injected with a toxic material extracted from the ackee, but this work does not support their finding; in fact, 17 per cent casein in the absence of riboflavin was unable to prevent severe loss of weight and death when ackee was present in the diet. In addition, animals fed a low-protein diet adequate in B-vitamins lost 20 per cent of their weight in 10 days, whether or not ackee was added to the diet. These authors may have inadvertently added riboflavin concomitantly with protein in raising the level of nitrogen in the diet.

Finally we were able to obtain a sample of hypoglycin *A* extracted from ackees and have demonstrated that, when given subcutaneously (60 μgm./gm. body-weight), its toxic effects may be alleviated by simultaneous injection (120 μgm./gm. body-weight) with riboflavin. De Renzo *et al.*[8] have suggested from their studies with rat liver mitochondria that hypoglycin *A* is metabolized to the true toxic agent, and it is of interest that our sample did not interfere with the microbiological assay of riboflavin.

This work is supported by two clinical observations. Hill[2] has reported that many medical officers in charge of districts and hospitals throughout Jamaica noticed severe signs of riboflavin deficiency in the majority of cases of illness in which the ackee was implicated, and confirmed this view during the epidemic of 1951. Secondly, the incidence of the condition has been less frequent in recent years, during which there has been a rising consumption of wheat flour[9], a relatively good source of riboflavin.

This work formed part of an M.Sc. thesis by one of us[10] and is being continued with the view of establishing the mode of action of the antimetabolite. We are indebted to Prof. C. H. Hassall and Dr. S. J. Patrick for samples of hypoglycin *A*.

RADIOBIOLOGY

Cæsium-137 in Spray-dried Danish Milk

The cæsium-137 content in Danish spray-dried milk has been measured in some fifty samples ranging in production time from 1949 to December 1959.

The measurements are carried out by γ-scintillation spectrometry using a Harshaw sodium iodide (thallium) crystal, 1½ in. diameter by 1½ in. thick, mounted in an electrolytic pure copper housing incorporating a quartz window. The 99-channel analyser used is of the analogue-to-digital conversion type built at this Laboratory and described elsewhere[1]. The resolution at 662 keV. is 8·3 per cent measured with a point source and approximately 10 per cent when a 800-gm. sample is counted. Fig. 1 shows sample container and detector in position inside the lead shield. The dried milk is measured without ashing or chemical treatment.

In Fig. 2 the upper curve shows a typical spectrum after subtraction of background. The potassium-40 peak at 1,460 keV. and cæsium-137 peak at 662 keV. are well resolved. No other peaks are significant. Sugar was used as background medium. The lower curve in Fig. 2 is that obtained with the cæsium-137 standard, while the points with their standard deviations are obtained from the upper curve by

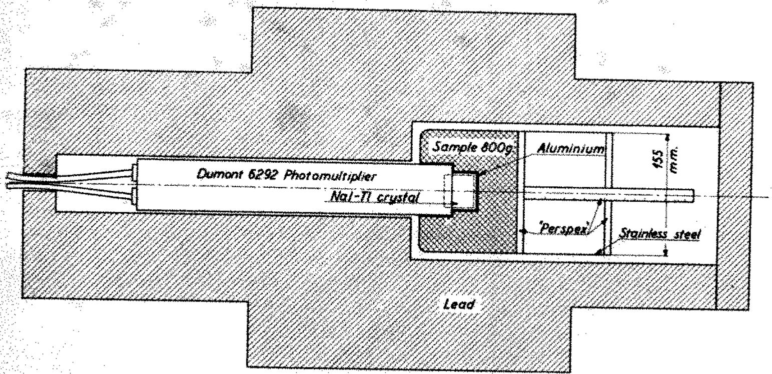

Fig. 1. Sample container and detector

subtracting the potassium-40 contribution. The points are seen to follow the cæsium-137 standard fairly well. 1 count/min. under the potassium-40 photopeak corresponds to 2·1 gm. of potassium in an 800-gm. sample, and 1 count/min. in the cæsium-137 photopeak corresponds to 98·1 μμc. of cæsium-137 in an 800-gm. sample.

The results are shown graphically in Fig. 3.

The peak value up to 1959 is about 20 μμc. cæsium-137/gm. potassium, which is rather low compared to figures given by E. C. Anderson *et al.*[2], who have measured two samples from Denmark and found 52 and 74 μμc. cæsium-137/gm. potassium respectively. Their samples were manufactured in June and September 1958. Our figures seem to correspond fairly well with those given by K. Løw and K. Edwarson[3] for Swedish milk but they are lower than the values quoted by Mayneord *et al.*[4] and by Booker[5].

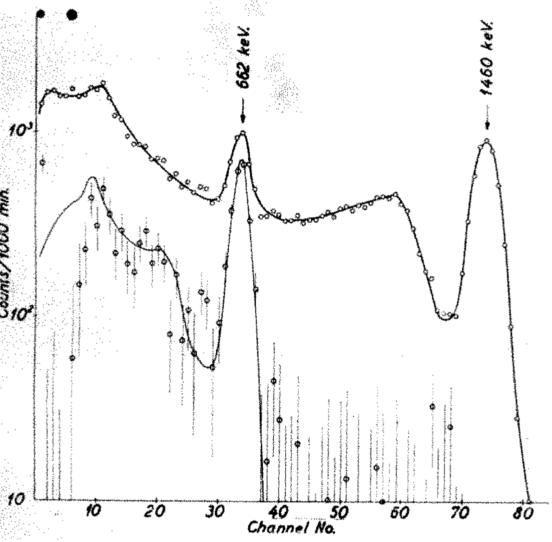

Fig. 2. Upper curve: spectrum of specimen after subtraction of background. Lower curve: spectrum of cæsium-137 standard

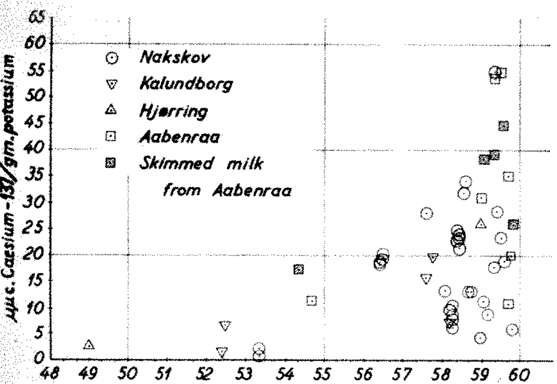

Fig. 3. Ratio of μμc. cæsium-137/gm. potassium in dried milk as a function of date of production

Maybe the relatively low content of cæsium-137 in Danish milk is due partly to the large amount of fertilizer used in Denmark. On the average, 3·2 gm. potassium is used per m.^{2} per annum. The average rainfall is 750 mm. in Aabenraa and 600 mm. in Hjørring per annum. No strontium determinations have so far been carried out on our samples.

Mechanism of the Radiation Effect on the Synthesis of Deoxyribonucleic Acid

WORK on the mechanism of the radiation effect upon the synthesis of deoxyribonucleic acid in human bone marrow cells *in vitro* indicated a biphasic X-ray dose-response curve[1]. To test the applicability of these findings to other mammalian cell systems, similar work has been carried out with mouse Ehrlich ascites tumour cells; this system also has the advantage of being a more homogeneous cell population than bone marrow.

Seven- to ten-day-old tumour was used; the ascitic fluid was immediately aspirated by syringe, suspended in heparinized supplemented Hanks's solution and centrifuged at 1,200 rev./min. for 10 min. The supernatant was discarded and the cells re-suspended in a medium consisting of 50 per cent supplemented Hanks's solution and 50 per cent human serum to a concentration of 10^7 cells/ml. Aliquots of 1 ml. were then placed in 16 screw-cap culture vessels, of which four served as controls and four for each X-ray dose-level. X-rays were produced by a 300 kVp. resonant transformer, 1·9 mm. copper half-value layer at a dose rate of 475 rads/min. Irradiation was so arranged that all the doses were completed simultaneously. ^{14}C–thymidine, 0·5 μc./ml. culture, was added immediately after irradiation and the vessels incubated for 2 hr. at 37° C. Synthesis of deoxyribonucleic acid was measured by counting the total radioactivity of washed cells on planchettes prepared by the method of Lajtha *et al.*[2]; the number of cells per planchette was checked by ultra-violet absorption spectrometry. The results are shown in Fig. 1; each point represents the mean of eight experiments.

As in human bone marrow, the curve is at least biphasic, though less clear-cut. A steep initial depression (S_1) is again followed by a shallower slope at higher doses (S_2). The mechanism by which

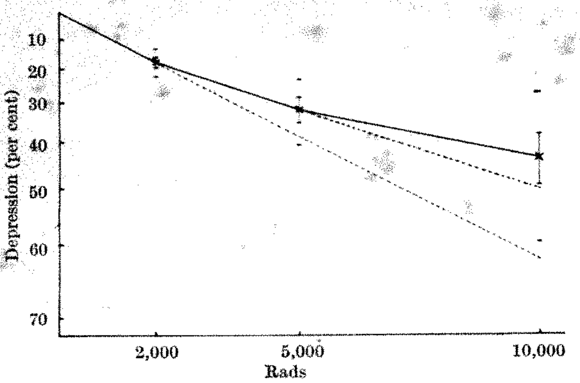

Fig. 1. X-ray dose-response curve, Ehrlich ascites cells *in vitro*. Each point represents the mean of eight experiments. Vertical bars indicate standard error of mean; standard deviation of individual experiments indicated by the short horizontal bars. Interrupted line from 2,000 to 10,000 rads indicates extrapolation of S_1 slope, that between 5,000 and 10,000 rads indicates dubious break in S_2 slope

irradiation inhibits synthesis of deoxyribonucleic acid is still unexplained; possibly S_1 represents some enzymatic inhibition[3] and S_2 the inhibition of the template replication of the deoxyribonucleic acid molecule. Variation in the radiosensitivity of the cells sufficient to explain the curve is unlikely, as autoradiographic work with ^{3}H-thymidine in similar experiments indicates a general shift of the grain counts to lower levels.

The effect of oxygen on the inhibition of synthesis of deoxyribonucleic acid by X-irradiation has been investigated for the initial (S_1) slope of the dose-response curve. Ehrlich ascites cells were suspended as before and placed in flat glass Petri dishes within a pressure vessel. The cell suspensions were equilibrated for 5 min. at room temperature with either 100 per cent oxygen or oxygen-free nitrogen and then rotated for 15 min. on an inclined turntable to ensure full equilibration of all cells with the gas phase. Irradiation was carried out while the cell suspensions were thus being rotated (300 kVp., 0·5 mm. copper + 1 mm. aluminium added filtration, dose-rate 280 r./min.). The cells were then incubated with ^{14}C–thymidine and planchettes were prepared as before. The results are shown in Fig. 2; at doses of both 800 and 2,000 rads (measured by ferrous sulphate), there was a markedly greater inhibition of the incorporation of ^{14}C–thymidine in the oxygenated suspensions. The ratio oxygen/nitrogen averaged 2·9.

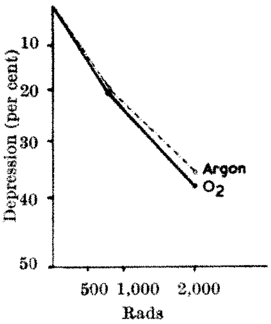

Fig. 3

Fig. 2. 'Oxygen effect', radiosensitivity of S_1 component. Each point at a given X-ray dose-level represents an experiment with quadruplicate controls

Fig. 3. Inability of 37 atm. argon + 1 atm. air to simulate anoxic conditions in modifying radiosensitivity of S_1 component. Each point at a given X-ray dose-level represents an experiment with quadruplicate controls

Ebert, Hornsey and Howard[4] noted that inert gases under pressure in the presence of normal atmospheric concentration of oxygen could simulate anoxic conditions in modifying radiosensitivity of several cell systems, including the production of abnormal anaphases in Ehrlich ascites cells. These cells show an 'oxygen effect' of a factor of 2·7–3·1 as demonstrated by Deschner and Gray[5]. To test an inert gas in this system, argon at 37 atm. + 1 atm. air was introduced over normally aerated cell suspensions in a pressure vessel and the vessel then rotated on the inclined turntable for 15 min. The control (oxygen) suspension was equilibrated for 5 min. with 100 per cent oxygen bubbled through water, then the vessel was rotated as before. The suspensions were irradiated and incubated as above. The results are shown in Fig. 3; the radiosensitivity in air + argon did not differ from that in oxygen at either dose-level.

The difference in the absolute values of the depression of deoxyribonucleic acid synthesis in oxygen between these experiments and those of Fig. 2 may be ascribed partly to the fact that the earlier experiments were performed with dry gas (permitting additional damage to the cells by dehydration and consequent hypertonicity of the medium), whereas in the latter water-saturated gas was used. It is significant, however, that in each experiment where both oxygenated and nitrogenated suspensions of the same tumour received identical treatment with the exception of the gas used, there was a marked difference between radiosensitivity in the two gases. By contrast, in the experiments in which oxygen and air + argon were used, there was no difference in radiosensitivity at either dose-level. The degree of depression shown in the dose-response curve in Fig. 1 suggests that the cell system was 'anoxic', as would be expected from the findings of Deschner and Gray[5], and that due to the closed system (rather than open Petri dishes) the cells were not additionally damaged by dehydration of the medium.

These experiments re-affirm the multiphasic (S_1, S_2) X-ray dose-response curve for the synthesis of deoxyribonucleic acid. They also indicate the dependence on oxygen of the radiosensitivity of the S_1 process; experiments to determine whether the S_2 process is similarly dependent on oxygen are in progress. The failure of inert gases to modify this response suggests that it is not due to effects at an intranuclear lipid interface where the inert gases have been postulated to act[4].

These experiments were supported by a grant from the Medical Research Council; one of us (R. J. B.) is British-American Exchange Fellow of the American Cancer Society.

BIOLOGY

Golgi Bodies and Golgi Zones in Molluscan Oocytes

In the cytoplasm of the oocytes of *Aplysia depilans* L. (Mollusca, Opistobranchia), during the first phases of growth, a large quantity of Golgi bodies or dictyosomes can be found. Such bodies can be observed with the optical microscope with the silver impregnation methods and they are generally arranged along a bent line (Fig. 1). The same bodies can also be observed with the electron microscope (Fig. 2), and in this instance they show a closed system of double parallel membranes (Fig. 5) and not an open system, as generally observed by previous authors. Inside these bodies[1] there are vacuoles with a clear content and vesicles with a dark content, which correspond to similar structures of the open system. In the oocytes of *Aplysia* vitellogenesis takes place following a radical transformation of Golgi bodies into yolk globules, as already observed by Parat[2] in *Aplysia punctata*.

Electron microscope observations showed that the following growth stages of such globules take place by means of peculiar particles which are characterized by a central clear zone and by a peripheral zone, that is, composed of dark granulations with a diameter of about 300 Å. The particles arrange themselves around each globule in the shape of a half-moon (Fig. 4), which is evident also in silver method preparations as observed with the optical microscope (Fig. 3). When the globules have reached their maximum in growth, these particles are no longer present, but a semi-lunar globule can still be observed (Fig. 6). It differs, however, from the previously cited half-moon as it cannot be impregnated by silver methods and it shows different ultrastructural peculiarities (Fig. 6). The further phases of vitellogenesis in *Aplysia* have been reported in earlier communications[3,4].

In the oocytes of *Patella coerulea* L. (Mollusca, Prosobranchia) dictyosomes like those of *Aplysia* cannot be found. The formation of yolk globules takes place from the beginning in direct connexion with the ergastoplasm[4,5]. This is formed by filaments of a thickness of about 200 Å., which carry dark granulations measuring about 300 Å. in diameter. The presence of a semi-lunar formation around growing yolk globules can be observed both with the silver impregnation methods with the optical microscope (Fig. 7) and with the electron microscope. This formation disappears when the globules have attained their full development. Such formation clearly corresponds to that formed by the dark granulations of 300 Å. in diameter, which are attached to the filaments.

The above results demonstrate, with reference to the Golgi apparatus, that it is possible to distinguish two types of elements which are both evidenced through the silver impregnation. The first elements have been found only in *Aplysia*, and they correspond, from the ultrastructural point of view, to typical Golgi bodies; the second elements, which have been found both in *Aplysia* and in *Patella*, show totally different characters. It is therefore highly probable that the semi-lunar zones, which surround the developing yolk globules, are the expression of peculiar physico-chemical conditions, that are connected with intense synthetic processes and favour silver precipitations at their level. When such synthetic processes come to an end, silver is no longer precipitated. This allows the distinction of two different aspects of the Golgi apparatus: one is represented by typical Golgi bodies or dictyosomes according to Grassé, Carasso and Favard[6], and another is represented by Golgi zones, which have a different constitution and are connected with intense synthetic processes.

Contrasting views regarding the different elements of the Golgi apparatus can thus be reconciled. Such solution was already foreshadowed by conclusions reached by a few authors, such as Levi[7] and Dalton[8]. Grassé's[9] contention that the Golgi zone has no reality and that the Golgi apparatus is a definite organelle present in any cell appears thus to be highly restrictive from this point of view.

Structure of the Outer Secondary Wall on Unbleached Spruce Sulphite Fibres

NUMEROUS investigators, in particular Emerton[1], Wardrop[2] and one of us[3], have reported on the structure of the outer secondary wall, S_1, of coniferous fibres. In all cases, these investigations were carried out on fragments which had been freed from the fibres by some form of mechanical action. Although the evidence that these fragments originated from the S_1 wall is excellent, the S_1 wall has never been seen intact on the surface of a fibre.

We are at present carrying out investigations on some properties of unbleached spruce sulphite fibres. The fibres discussed here were mechanically treated in a 2-litre disintegrator for 80 min. at a consistency of 1 per cent. After the disintegration, the fibres were screened thoroughly twice to remove the fine fragments released by stirring. Samples of the screened fibres were dried on to slides and without further treatment examined in a microscope under reflected light. (Zeiss microscope, model *W*, epi-illumination *IIB*.) We found attached to many fibres typical S_1 fragments. In a few cases such as that shown in Fig. 1, the S_1 structure was clearly visible on the surfaces of the fibres. The alternate dark and bright lines between the fibre and the upper fragment are interference fringes (Newton's rings) formed in the wedge-shaped gap between the partially unravelled S_1 fragment and the slide[4] (see cross-sectional view of fibre in Fig. 2). The presence of the interference fringes is strong evidence that the unravelled S_1 fragment is attached to the top surface of the fibre.

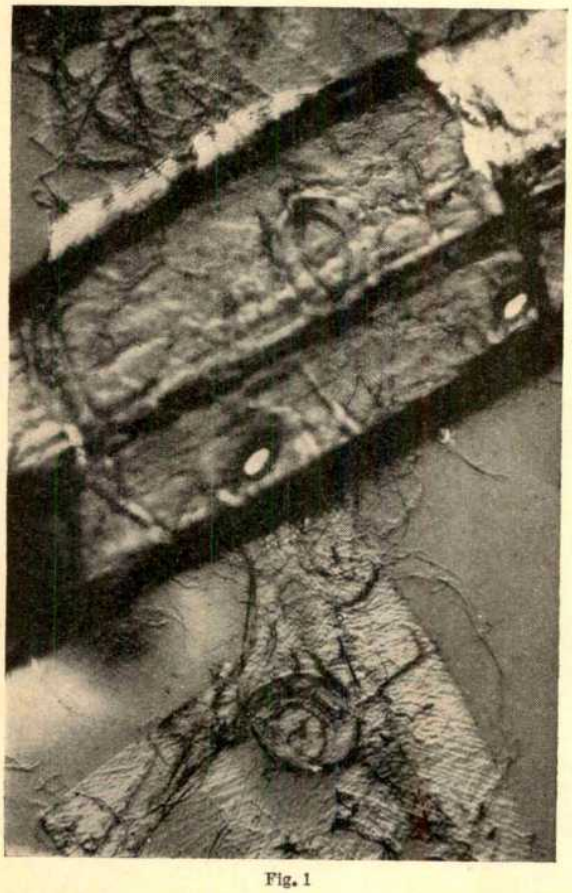

Fig. 1

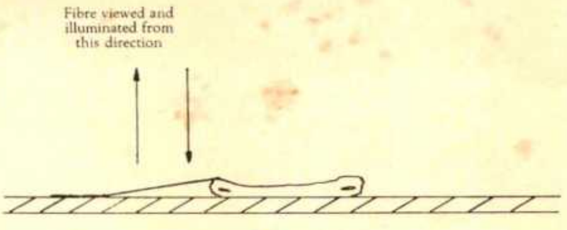

Fig. 2

The angle between each of the two sets of fibrils and the fibre axis (fibrillar angle) is about 50° (five measurements). The same value was obtained for the S_1 fragment in the upper portion of Fig. 1. Assuming that the longitudinal fibre axis of the other fragment is perpendicular to that of the fibre, its fibrillar angle is about 60°. These values agree well with those reported in refs. 1, 2 and 3.

Occurrence of *Falkenbergia rufolanosa* on the West Coast of Scotland

PERIODIC reports during the past twenty years[1-4] have noted the appearance of *Asparagopsis armata* and its associated form, *Falkenbergia rufolanosa*, in a number of localities in western Ireland and the south and south-west coasts of England. Although the southern records reported the two forms appearing almost simultaneously, recent evidence suggests that *Falkenbergia* is spreading round the British coasts more widely than *Asparagopsis*[5-7]; and this would seem to confirm the suggestion of Thomas[8] that the two differ in their ecological requirements.

Further evidence of the spread of *Falkenbergia* is seen in its appearance on the coast of Scotland. During a survey of the inter-tidal zone of the coasts of the Hebridian island of Colonsay at the time of very low tides early in September 1959, filaments of a small polysiphonous alga showing three pericentral cells around each cell of the central filament were found on two shores: (*a*) intermingled with other small drift algae collected from the Strand between Colonsay and Oransay, and (*b*) as quite large, bright pink 'pom-poms' growing on *Cladophora rupestris* in Cable Bay, a small sandy bay at the south-east of Colonsay, where, again, it occurred much intermingled with other small epiphytic algae such as *Ceramium rubrum*, *Sphacelaria bipinnata*, *Lomentaria articulata* and *Achrochaetium* sp. This alga agrees with descriptions given for the vegetative state of *Falkenbergia rufolanosa*[8,9]. The filaments forming the well-marked 'pom-poms' were short and not much branched except towards the tips: they had the appearance of young, developing axes with markedly active apical cells. All the plants examined were sterile. On several filaments, propagules of *Sphacelaria bipinnata* were attached and were developing as epiphytes of the *Falkenbergia*.

It is hoped that other marine ecologists will keep a watch for further appearances of *Falkenbergia* in northern waters: it will be of considerable interest to see if it is followed in the Hebrides by *Asparagopsis*, or if the different distribution pattern of the two forms receives further confirmation.

Perfect Stage of *Sclerotium rolfsii* Sacc.

THE perfect stage of *Sclerotium rolfsii* Sacc. has been reported by several workers[1-6]; however, the conditions under which its development takes place have not been investigated thoroughly. An attempt was therefore made to find out the various nutritional and environmental factors which affect the development of the perfect stage.

The fungus was isolated from rotted potato tubers and grown on different media; also under different conditions of temperature, hydrogen-ion concentrations, and relative humidities. Different sources of carbon and nitrogen, as well as different concentrations of their best sources, were also tried, but no success was met with, until one day a plate of standard Brown's agar medium containing cultures of *S. rolfsii* and lying in the cupboard for 1½ months was seen developing the fruiting body. An experiment was set up with seven agar media, namely, potato-dextrose, oatmeal, maize meal, host extract, Richard's, Czapek's and Brown's. Three plates of each were incubated at 25° C. and at room temperature in the cupboard.

The fruiting body developed only in the three plates containing Brown's agar medium incubated at room temperature during a period of 33–39 days. The mean maximum and minimum room temperatures for the period under observation were 19·9° C. and 14·4° C. respectively. This experiment was again repeated when the mean maximum and minimum room temperatures were 23·5° C. and 17·3° C. respectively, and similar results were obtained.

The descriptions and measurements of the fruiting body, basidium, and basidiospores resembled those reported earlier[2,4]. Basidiospores, when planted on potato dextrose agar, germinated and grew to form a mycelial mat and sclerotia. The mycelial, sclerotial, and growth characters of the basidiosporal cultures resembled those of the parent culture.

Brown's agar medium which developed the perfect stage is poor in nutrients as compared to the rest of the media. The special medium used with success by Mundkur[4] was also poor in nutrient. Curzi[2] also reported that sporulation in *S. rolfsii* took place earlier and was more abundant in media poor in nutrients as compared with media rich in nutrients. Reports of various workers[2,4,5] also indicate wide variation in the temperature requirement for the development of the perfect stage.

The development of perfect stage in *S. rolfsii* thus seems to depend both upon nutrient and temperature, and Brown's agar medium incubated at room temperature ranging between a mean maximum and minimum of 21·7° C. and 15·9° C. for 33–39 days is suitable for the development of the perfect stage.

BACTERIOLOGY

Isolation of Mutants of *Bacillus subtilis* requiring D-Glutamic Acid

ALTHOUGH synthetic pathways of the L series of amino-acids have been studied extensively by the use of biochemical mutants of micro-organisms, there appears to be no published account of the synthesis of the D series of amino-acids using similar experimental techniques. Meanwhile, because D-glutamic acid is known to be an essential component of the cell wall and capsular fractions of a certain kind of bacteria[1,2], an attempt to obtain mutants requiring D-glutamic acid for growth is still valuable. With this idea, induction and isolation of mutants from a wild strain of *Bacillus subtilis K* requiring D-glutamic acid was attempted.

Minimal medium was prepared as prescribed by Gray and Tatum[3] (L-asparagine was eliminated), adding 0·1 per cent glucose for liquid medium and 0·5 per cent for solid medium. To allow the growth of mutants requiring D-glutamic acid, if any existed, a special medium (*DG*) consisting of 100 μgm./ml. of D-glutamic acid and the components in the minimal medium was prepared and used in place of the so-called complete medium. Spores of the wild strain were harvested from a 10-day culture on Burkholder's nutrient agar slant[4], and a suspension

Table 1. Response Pattern of the Five Mutants Isolated

Amino-acids (100 μgm./ml.)	Mutant strains 1*a*	2*a*	3*a*	4*a*	3*d*
D-Glutamic acid	+	+	+	+	+
D-Aspartic acid	+	+	+	+	+
D-Alanine	+	+	−	−	+
L-Glutamic acid	−	−	+	+	−
L-Aspartic acid	−	−	+	+	−
L-Alanine	+	+	−	−	−
DL-Glutamic acid	+	+	+	+	+
DL-Aspartic acid	+	+	+	+	+
DL-Alanine	+	+	−	−	+
Minimal medium	−	−	−	−	−
Casein hydrolysate plus D-glutamic acid	+	+	+	+	−

containing 10^6–10^7 spores in 2 ml. of sterile saline was exposed to X-rays. The survival ratio at a dose of 144,000 röntgens was 20 per cent. After appropriate dilution, the cells were plated on *DG* medium. The replica plating method devised by Lederberg and Lederberg[5] was applied to the colonies that appeared on the plates, and such colonies which showed positive response to the *DG* medium, but not to minimal medium, were selected.

As a result, four out of about ten thousand colonies tested were proved to be mutants requiring D-glutamic acid. These mutants, 1*a*, 2*a*, 3*d* and 4*a*, are fairly stable though 3*d* gave rise to a new mutant, 3*a*, spontaneously. Growth response of these strains to D and L amino-acids was judged by shake culture method using about 10^6 cells/ml. as inocula. As seen in Table 1, all of them require D-glutamic acid for growth, but response to D-aspartic acid, D-alanine, L-glutamic acid, L-aspartic acid and L-alanine is different from strain to strain. For example, strain 3*d* grows on a medium containing either D-glutamic acid, D-aspartic acid or D-alanine, while strains 3*a* and 4*a* grow on either a D-glutamic acid, D-aspartic acid, L-glutamic acid or L-aspartic acid supplemented medium. It is strange that strain 3*d* cannot grow on a medium consisting of casein hydrolysate and D-glutamic acid; but this phenomenon may be due to a mutual effect between D-glutamic acid and other amino-acids.

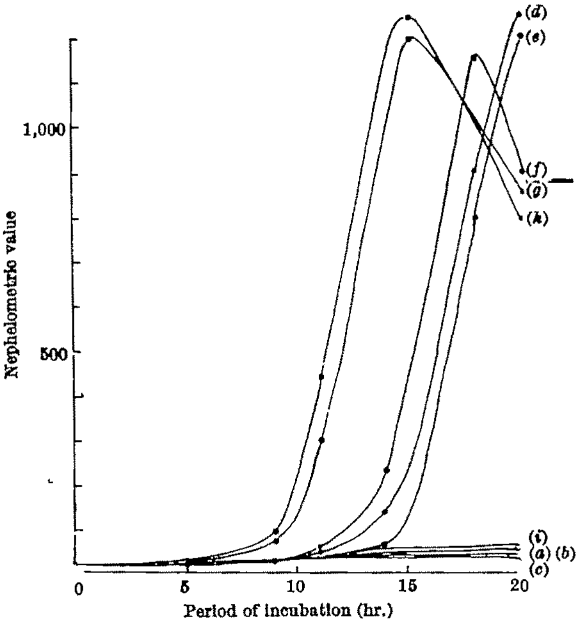

Fig. 1. Growth of strain 3*d* in media supplemented with (*a*) L-glutamic acid, (*b*) L-aspartic acid, (*c*) L-alanine, (*d*) D-glutamic acid, (*e*) D-aspartic acid, (*f*) D-alanine, (*g*) DL-glutamic acid, or (*h*) DL-aspartic acid. (*i*) is minimal medium

Fig. 1 shows growth-curves of strain 3*d* in media supplemented with 100 μgm./ml. of D, L or DL amino-acids, where cultivation was carried out in Monod tubes on a shaking machine at 37° C. Moreover, the minimal amount of D-glutamic acid sufficient to achieve full growth of strain 3*d* was determined to be 5–10 μgm./ml. The number of viable cells decreased rapidly when strain 3*d* was placed in a medium devoid of D-glutamic acid.

T_6 and λ Phage Adsorption on Protoplast-like Bodies of *Escherichia coli*

During the past few years, methods have been developed for preparing spherical units of Gram-negative bacteria such as *E. coli*, which have often been described as 'large bodies' or 'protoplasts'. Unlike the protoplasts of Gram-positive bacteria, these spherical forms are also very sensitive to osmotic change. Whereas it can be shown by various methods that the cell wall is removed in the case of *B. megatherium*, this has not been proved conclusively for the spherical forms of *E. coli*. Since the cell wall of *E. coli*, unlike that of Gram-positive bacteria, contains a lipoprotein component as well as lipopolysaccharide[1] and at least four of five methods of preparation for spherical forms involve only polysaccharides, it is very probable that the spherical forms of *E. coli* are surrounded by cell-wall remains. If this is really the case, we may assume that these forms adsorb at least some of those phages, towards which the rod-shaped, normal cell is sensitive.

We have therefore investigated the adsorption of the T_6 and λ phages on spherical forms of *E. coli* strains.

This communication deals with the adsorption of phages T_2, T_6 and λ_{hc} on spherical forms of *E. coli*[2], strains *B*, 173–25 or *S*, which have been produced either with lysozyme[2a], penicillin[2b], phage enzyme[2c], glycine[2d] or by deprival of diaminopimelic acid[2e].

In general, the standard phage techniques, as described by Adams[3], have been used. Special techniques will be published in detail elsewhere. Normally, *E. coli* cells grown up to 2–5 × 10^8/ml. or dilutions 1 : 3–1 : 50 of overnight cultures were used. The conversion to spherical forms was made in media containing 12 per cent sucrose. Such conditions were chosen that at least 99 per cent of the cells were changed to the spherical form, that is, the survival rate after an osmotic shock (dilution 1 : 100 in phosphate-buffer 0·1 *M*, *p*H 7·0) was never higher than 1 per cent.

The adsorption of phages was studied in sucrose-broth (~100 gm. sucrose, 11 gm. peptone, 5·8 gm. sodium chloride/l.) over a period of 10 min. (phage T_2) or 15 min. (phages T_6 and λ_{hc}) at 37° C. Non-adsorbed phage was recovered after killing of the infected complexes with chloroform. The micro-

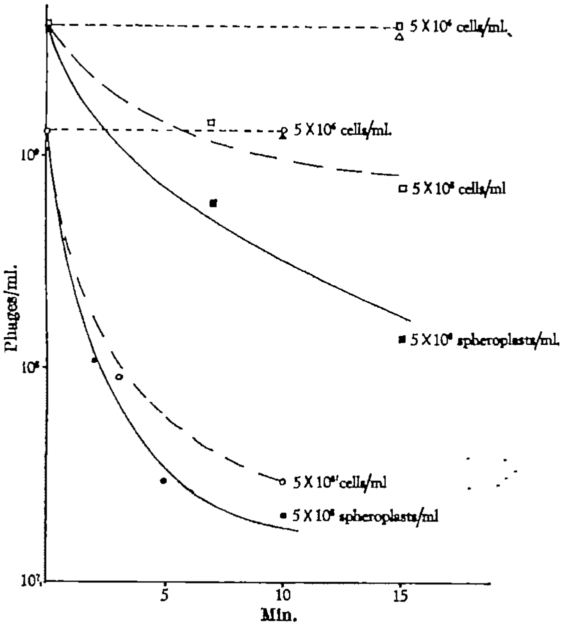

Fig. 1. Adsorption of phages T_2 and T_5 (● and ■) to spheroplasts obtained by treatment with 1,000 U./ml. penicillin in aerated culture at 37° C. during 75 min. (full symbols), to *E. coli* cells (empty symbols) and inactivation by cell-free supernatant of conversion medium (△)

scopically determined titre of the washed spherical forms was $\sim 5 \times 10^8$/ml. in experiments with phages T_2, T_5 and $\sim 10^5$/ml. in experiments with phage λ_{hc}.

Glycine treatment was also carried out in normal broth without addition of sucrose. In this case the conversion was only controlled by phase-contrast microscopy and the adsorption was measured in a sucrose-free medium.

As controls we used the conversion medium from which the cells had been removed by centrifugation, as well as normal *E. coli* cells of the same concentration as the spheroplasts and in a dilution 1 : 100. In this way we were able to take into account a possible adsorption on rod-shaped, non-converted bacteria and the inactivation of phage by soluble cell-wall material.

The comparison of adsorption by normal rod-shaped cells and spherical forms of equal titre should, under certain conditions, allow quantitative conclusions concerning the proportion of receptor substance still remaining.

A typical result is shown in Fig. 1. Phages T_2 and T_5 are adsorbed at the same rate on to *E. coli* cells as on to spherical forms (obtained by treatment with 1,000 U./ml. penicillin in aerated broth–sucrose medium during 75 min. at 37° C.).

The same rate of adsorption of the phages on both normal cells and spherical forms makes the assumption possible that the receptor substances for T_2 and T_5 phages remain quantitatively on the spheroplasts. But this assumption must be verified by further investigations in which a comparison between the highest possible number of adsorbed phages per spheroplast and per rod-shaped bacterium is made.

Similar results were obtained in parallel experiments with *E. coli* converted by phage-enzyme, lysozyme, glycine or by deprival of diaminopimelic acid and phages T_2 or T_5 and λ_{hc}. These results provide strong evidence that *E. coli* cells, after conversion in liquid suspension, are not true protoplasts since these are defined as being the protoplasm completely depleted of the cell wall. Indeed, the receptors for the phage T_2 have been shown to be situated in the cell wall. It seems to be obvious, in general, that the receptors should be at the surface of the wall. In these circumstances the term 'spheroplast' is preferable to protoplast as suggested by S. Brenner and others[4].

We are now studying the adsorption of the other T_i phages. This may be another way to investigate the localization of phage receptors in the cell-wall components.

On the completion of this work we read the paper by G. Dénes and L. Polgár[5] on T_2 phage multiplication in 'protoplasts' obtained by penicillin treatment, and found it in close agreement with our results.

These investigations were started in the Laboratoire de Biophysique, Geneva. We wish to thank Prof. E. Kellenberger and his collaborators for their many suggestions and for the courtesy of providing us with phage and bacterial strains. We also thank Dr. McQuillen, Cambridge, from whom we received *E. coli* strain 17325 and a sample of diaminopimelic acid.

We are also indebted to Prof. A. Butenandt for his encouragement throughout the course of this work, and for making the studies in Geneva possible.

The a–z–z_{35} Group of *Salmonella* Antigens

IN the course of establishing the antigenic formula for a new *Salmonella* serotype, *S.* greenside, its specific-phase flagellar antigen (*z*) was found to differ from the usual type as seen in *S.* poona, but to be identical to that of *S.* bulawayo[1]. Taylor, in describing the antigen z_{34} of *S.* chittagong, mentioned its relationship to both *z* of *S.* poona and *a* of *S.* paratyphi A.[2]. Common factors between *a*, *z*, and the antigen z_{35} of *S.* cairina were also described by Kauffmann[3], although z_{35} in this case was found to be slightly different from that of *S.* chittagong.

In view of these findings, an attempt has been made to clarify the relationships between these antigens by means of a series of agglutinin-absorption tests.

Rabbit antisera preserved with 50 per cent glycerine were used throughout these experiments. Sera prepared from biphasic *Salmonellae* were given an initial absorption with packed bacterial cells containing antigens corresponding to the unwanted flagellar phase.

Absorption tests were done by emulsifying packed cells in 5-ml. volumes of each serum, incubating at 37° C. for 18 hr., and removing the supernatant fluid after centrifugation. This procedure was repeated

Table 1. FLAGELLAR AGGLUTINATION REACTIONS BEFORE AND AFTER ABSORPTION

Agglutinable suspensions	Antisera											
	z (poona)	z (poona) absorbed with		z (bulawayo)	z (bulawayo) absorbed with		z_{35}	z_{35} absorbed with			a	a absorbed with z_{35}
		z (bulawayo)	z_{35}		z (poona)	z_{35}		a	z (poona)	$a + z$ (poona)		
S. poona (z)	2,560	160	1,280	2,560	0	320	640	160	0	0	0	0
S bulawayo (z)	640	0	160	2,560	80	640	320	160	0	0	0	0
S. chittagong (z_{35})	640	0	0	640	0	0	2,560	1,280	1,280	320	40	0
S. paratyphi A. (a)	0	0	0	0	0	0	1,280	0	640	0	2,560	2,560

Note 0 equals negative at 1/10 dilution. Figures indicate reciprocals of titres.

until no more agglutinins against the absorbing antigen could be demonstrated.

Agglutination tests were carried out in a 52° C. water-bath for 2 hr., using dilutions of serum in 0·85 per cent saline, and equal volumes of formalinized antigenic suspensions adjusted to approximately 1×10^9 bacilli per ml. The final serum dilutions ranged from 1/10 to 1/5120.

Comparison of the reactions before and after absorption shows that although a and z bear no direct antigenic relationship to each other, they each contain a fraction in common with z_{35} (Table 1).

The z complex can also be subdivided into two types, each of which has a specific factor and a factor common to both types, which includes the component shared with z_{35}.

Cross-absorption tests with z_{35} of *S.* cairina confirmed that it was not completely identical to z_{35} of *S.* chittagong, but showed that it shared the same factors with a and z.

Cultures of all z-containing *Salmonellae* described in the Kauffmann–White scheme were acquired from the National Collection of Type Cultures in London, or from the International Salmonella Centre in Copenhagen. Each culture was tested against specific factor sera prepared by saturating z (poona) and z (bulawayo) antisera with their heterologous antigens. All the cultures were agglutinated by one or other of the specific sera, thus forming two distinct groups (Table 2). It is of interest that the majority of the z_b group originated in central and southern Africa, including three first described from these laboratories (*S.* alexander, *S.* greenside, and *S.* rand).

Agglutinable suspensions	Antisera			
	(a_2) *S.* miami absorbed with *S.* durban	(a_3) *S.* miami absorbed with *S.* paratyphi A.	(a_4) *S.* paratyphi A absorbed with *S.* miami	*S.* paratyphi A. absorbed with *S.* chittagong
S. paratyphi A. (a_1,a_3,a_4)	160	0	40	2,560
S. durban (a_1,a_3)	0	40	0	640
S. miami (a_1,a_2,a_3)	320	80	0	640
S. chittagong (z_{35})	0	0	0	0

le Minor[4] has shown that the a antigen is a complex one, divisible into four components, of which *S.* paratyphi A. possesses three (a_1, a_3, and a_4). Further tests were now undertaken to see which, if any, of these factors was the one shared with z_{35}.

The results (Table 3) confirm le Minor's findings, and show that the antigen shared with z_{35} is a part of the a_1 fraction. This is proved by the inagglutinability of z_{35} in specific factor sera for a_2, a_3, and a_4, and by the fact that an a antiserum (*S.* paratyphi A.), after absorption with z_{35}, still contains agglutinins for the antigens of *S.* paratyphi A., *S.* miami, and *S.* durban.

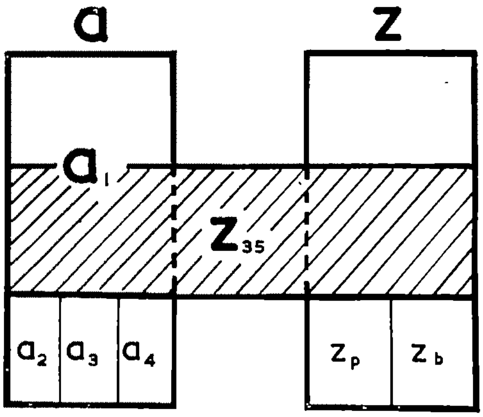

Fig. 1. Diagrammatic illustration of the relationships between the flagellar antigens a, z and z_{35}

The results of this series of experiments are summarized diagrammatically in Fig. 1. It will be seen that both the a and z antigens occur in different forms, each consisting of a common major fraction and one or more specific minor fractions. z_{35} shares one component with part of a_1, and a different component with part of the major fraction of z.

VIROLOGY

Antigenic Structure of Non-Infectious Adenovirus Materials

HeLa cells infected with adenovirus type 5 produce, in addition to virus particles, three non-infectious materials previously named antigens *A*, *B* and *C*[1]. These antigens can be separated by electrophoresis[1] and by chromatography on diethylaminoethyl cellulose columns[2]. Antigen *B* corresponds to the protein factor responsible for the early cytopathic action of adenoviruses in HeLa cell cultures[3,4] and possibly also to the cell-detaching factor described by Rowe *et al.*[5]. Antigens *A* and *C*, but not antigen *B*, contain deoxyribonucleic acid[6]. A comparison of these three antigens by gel-diffusion precipitation tests revealed a partial identity of antigens *B* and *C* and absence of antigenic relationship of either of these two materials with antigen *A* [1].

In the present investigation, an attempt was made to establish more precisely the relationship between antigens *B* and *C*. The virus material used was obtained from HeLa cells infected with the prototype strain of adenovirus type 5. A partially purified antigen was prepared by treatment of the infected cells with the fluorocarbon compound 'Arcton 63' (Imperial Chemical Industries, Ltd., London, S.W.1) as described by Pereira and Valentine[7]. Chromatographic fractionation was carried out on diethylaminoethyl cellulose columns at *p*H 6·5, using stepwise elution with sodium chloride concentrations varying from 0·01 to 0·35 *M* in 0 05 *M* steps. The antiserum used throughout was from a rabbit immunized with the unfractionated virus material.

The complex nature of antigen *B* was first suggested by the fact that digestion of this antigen by 0·1 per cent crystalline trypsin at *p*H 7·4 for 1 hr. at 37° C. resulted in complete abolition of its cytopathic action for HeLa cells while its complement-fixing activity remained practically unchanged. The effect of trypsin on the behaviour of antigen *B* in gel-diffusion precipitation tests was next investigated. The results of a representative test are shown diagrammatically in Fig. 1. The reaction between antiserum and unfractionated antigen gives three precipitation lines corresponding to antigens *A*, *B* and *C* as indicated. Antigen *B* isolated by chromatography gives a single precipitation line continuous with the corresponding line of the original antigen and showing reactions of partial identity with antigen *C* and of non-identity with antigen *A*. After trypsin digestion, the same antigen *B* preparation gives a single precipitation line showing reactions of identity with antigen *C* and non-identity with antigen *A*. This result suggests that antigen *B* is a complex of a trypsin-sensitive protein with the trypsin-resistant antigen *C*.

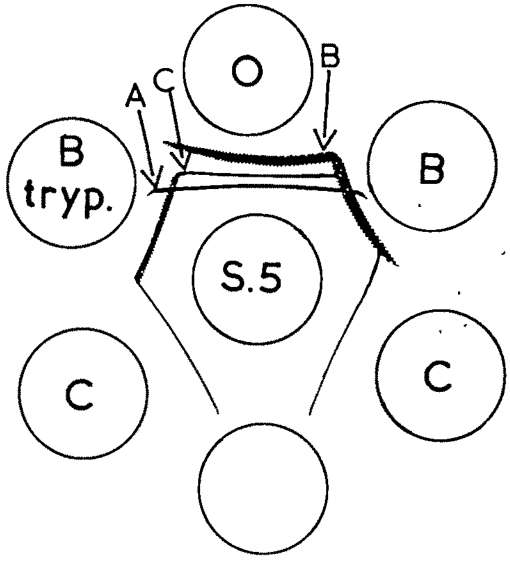

Fig. 1. Gel-diffusion precipitation test between adenovirus type 5 antiserum (*S* 5) and homologous antigens. *O*, Unfractionated antigen; *B*, antigen *B* isolated by chromatography; *B* tryp., the same antigen *B* preparation digested by trypsin; *C*, antigen *C* isolated by chromatography

This suggestion is supported by chromatographic studies shown in Fig. 2. The upper curve in this figure shows the fractionation of the original virus material into three antigenic components previously shown by Klemperer and Pereira[2] to correspond to antigens *A*, *B* and *C* with elution peaks at 0·275, 0·15 and 0·05–0·075 *M* sodium chloride respectively. The two eluates with highest complement-fixing titres in the band corresponding to antigen *B*, namely, the 0·15 and 0·175 *M* eluates, were pooled and divided into two equal parts, one of which was digested by trypsin under the conditions mentioned above. Both parts were dialysed against 0·01 *M* phosphate buffer at *p*H 6·5 and re-chromatographed under the same conditions as those used for the original antigen. Complement-fixation titres of the eluates are shown in the middle and lower curves of Fig. 2 for untreated and trypsinized materials respectively. The untreated antigen was eluted essentially in a single band with a peak at 0·2 *M* sodium chloride. The difference in position of this elution band as compared with that of the corresponding antigen in the original run is difficult to understand; it could be due to displacement effects caused by antigens or other components present in the starting material. The trypsinized antigen, in contrast, was eluted at lower concentrations of sodium chloride, with a peak corresponding closely in position to that of antigen *C* in the original run.

The nature of the antigenic component common to antigens *B* and *C* was further investigated by staining the gel-diffusion precipitation lines with acridine orange following the technique developed by Allison and Armstrong[8]. It had been previously shown by this technique[6] that antigen *C* present in unfractionated virus materials was stained by acridine orange, giving a strong yellow-green fluorescence; this indicates the presence of deoxyribonucleic acid in this antigen. No such staining reaction was, however, obtained with precipitation lines of antigen *B*. Identical results were obtained with antigens fractionated by chromatography, and no deoxyribonucleic acid could be detected by this method either in untreated or in trypsinized antigen *B*. The antigenic component common to antigens *B* and *C* is shown, therefore, to be free of deoxyribonucleic acid.

For convenience, we will designate the trypsin-sensitive component of the *B* complex as antigen β and the trypsin-resistant component common to *B* and *C* as antigen γ. The antigenic factor so far identified in *A* will be designated antigen α. The various components of non-infectious adenovirus type 5 antigens are shown in Table 1. It should be pointed out that the components listed there may account

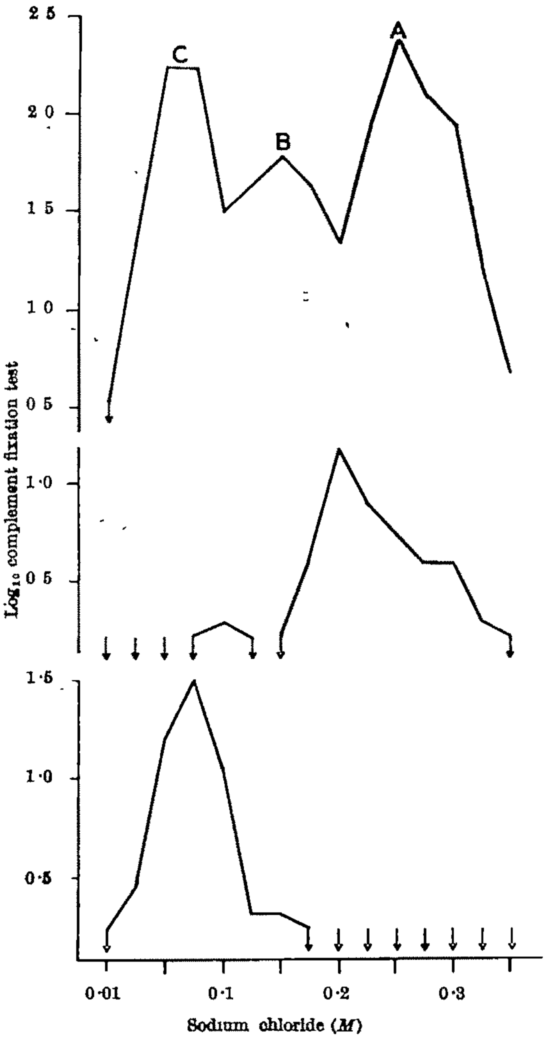

Fig. 2. Chromatography of adenovirus type 5 antigens on '*DEAE*-cellulose' columns. Stepwise elution with increasing concentrations of sodium chloride at constant *p*H (6·5). Eluates tested by complement fixation against adenovirus type 5 antiserum. Top curve, original virus material; middle curve, rechromatography of antigen *B* fractions (0·15 and 0·175 *M* eluates); lower curve, same as above, rechromatographed after trypsin digestion

for only part of the structure of antigens *A*, *B* and *C*. It is possible that the deoxyribonucleic acid components of antigens *A* and *C* may be nucleoproteins rather than pure deoxyribonucleic acid. This or additional factors not detected by the methods used in the present study might explain some anomalies apparent in the chromatographic behaviour of the antigens studied. A complex of antigen γ with deoxyribonucleic acid would be expected to elute from diethylaminoethyl cellulose at higher molarities than a complex of the same γ with another protein. The fact that antigen *C* is eluted from the columns before antigen *B* (Fig. 2) suggests, therefore, a higher complexity of the system.

The present findings might help to explain the possible relations of the antigens under study with virus particles and with the protein crystals free of deoxyribonucleic acid observed by Leuchtenberger and Boyer[9] and by Morgan *et al.*[10] in nuclei of HeLa cells infected with adenovirus type 5. It is tempting to speculate, for example, that complexes of antigen γ with nucleic acid or nucleoprotein would tend to aggregate to form virus particles whereas complexes of the same antigen with protein β would form the protein crystals free of deoxyribonucleic acid.

Table 1. Components Identified in Non-infectious Adenovirus Type 5 Antigens

Antigen	Component
A	α deoxyribonucleic acid
B	γ β
C	γ deoxyribonucleic acid

SOIL SCIENCE

Capillary Movement of Nitrate towards Tropical Soil Surfaces

As in many other parts of the tropics, accumulation of nitrate in the top inch of soil during the dry season has been observed at Katherine, Northern Territory, Australia, on a red sandy clay loam. The accumulation could be caused by a complex of processes of a physico-chemical, photo-chemical, biological or physical nature. Experiments at Katherine have shown that capillary movement has been obscured, rather than overlooked, as the main cause.

During the 1959 dry season, changes in chloride and nitrate content in the top soil of a clean fallow were followed in the 0–1, 1–2, 2–3, 3–6, 6–9 and 9–12 in. layers from April 20 onwards, that is, one day after the last rain in April. Normally, the rains end in April and are followed by a five-months rainless period. However, in 1959, 0·95 in. fell between May 18 and 24.

Chloride was applied to the soil surface on March 2 in the form of sodium chloride at the rate of 2,000 lb./acre. Leaching of this ion by the subsequent 13 in. of rain resulted on April 20 in a chloride distribution over the top 12 in. of soil as is given in Fig. 1. Comparative fallow plots receiving no salt were sampled for nitrate. Its distribution over the top 12 in. on the first sampling date is given in Fig. 2.

The progress of accumulation of chloride and nitrate near the soil surface is shown in Figs. 1 and 2. Chloride content in the top inch increased significantly from 950 p.p.m. on April 20 to 2,977 p.p.m. chloride on June 22, and nitrate significantly from 38 to 229 p.p.m. nitrate over the same period. Chloride content at this level decreased temporarily after the rain in May, but increased again in the following dry weather. Nitrate content in the top inch did not decrease after the May rain, due presumably to a short period of nitrification at adequate moisture content, but showed a concentration pattern similar to that of chloride in the 12 in. profile throughout the sampling period.

More detailed sampling of the top 1¾ in. of the soil, in ¼ in. layers, revealed that the level of maximum accumulation is not at the surface but at a depth determined by the bottom of the soil crust. At this level the soil has an open and loose structure, and below it the soil is hard and compacted. A typical nitrate stratification in the top 1¾ in. of the soil, measured in August at one point, is given in Fig. 3. The level of maximum nitrate accumulation has consistently been found to coincide with the bottom of the soil crust and is not related to actual soil depth. Chloride accumulation shows an exactly similar relationship with the crust.

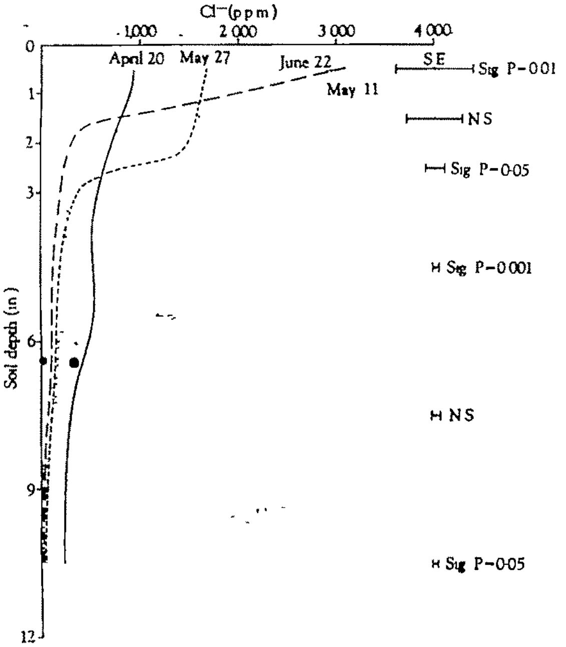

Fig. 1

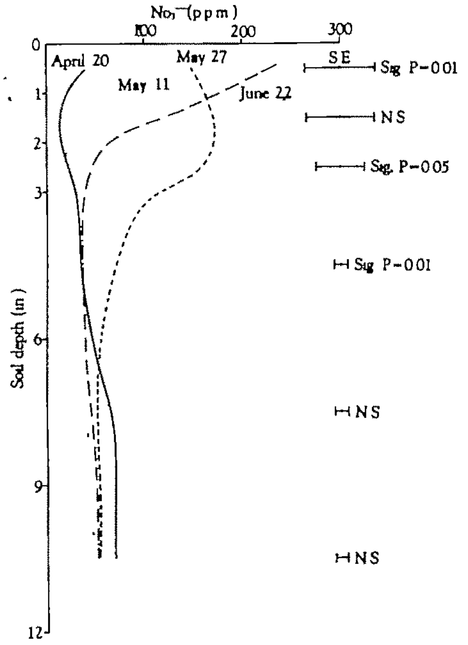

Fig. 2

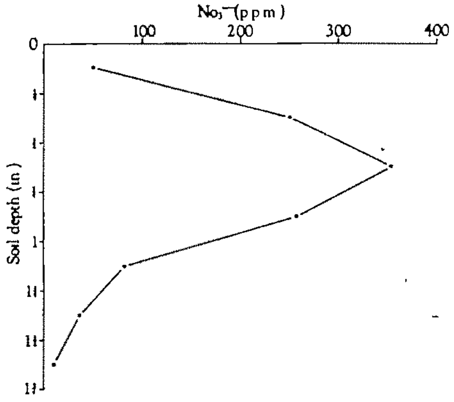

Fig. 3

This relationship and the fact that nitrate and chloride stratifications are affected in similar ways by rain and a following dry period indicate strongly that the main cause of nitrate accumulation near the surface of the soil is a physical one, for which capillary movement is the only acceptable explanation.

Further details will be published elsewhere.

Complexes of Calcium-Montmorillonite with Polymers

Various types of polymers have been used to stabilize soil crumbs[1-5], the polymers linking together the domains of clay crystals within the crumbs[6]. To obtain further information on the nature of clay–polymer bonds, the interaction of calcium-montmorillonite with a wide range of polymers has been studied.

A neutral suspension of calcium-montmorillonite in 2×10^{-3} *M* calcium chloride was prepared from the $< 2\mu$ fraction of Wyoming bentonite (Volclay). To an aliquot of this suspension a known amount of organic material was added as a neutral solution. The calcium chloride present ensured that complexes formed rapidly after mixing, large flocs appearing within a few seconds. The clay was then filtered through a sintered glass funnel and later dried over phosphorus pentoxide to form an orientated disk 0·02 mm. thick.

Flakes about 4 mm. square were cut from the disk and their thickness measured with a travelling microscope reading to 0·002 mm. The swelling of the flake was determined after immersion in *M* calcium chloride and then in progressively more dilute calcium chloride solutions. The effect of adding 1·0 per cent of various materials on the swelling of calcium-montmorillonite is shown in Fig. 1, the ordinate being the ratio of the increase in thickness of the

Table 1. EFFECT OF LEACHING ON THE DISPERSION OF CALCIUM-MONTMORILLONITE COMPLEXES

Leaching treatment	Dispersion medium	Addition			
		None	1·0 per cent		
			Group 1	Group 2	Group 3
			Sodium alginate Sodium pectinate Sodium carboxy-butyl cellulose Sodium humate (from soil)	Sodium polyacrylate Polyacrylamide	Polyvinyl alcohol Polyglucosans Polyfructosans
N sodium chloride	*N*/100 sodium chloride	Dispersed in 2–3 hr.	Dispersed in 2–3 hr.	No dispersion	No dispersion
Neutralized 0·15 *M* sodium pyrophosphate	*N*/10 sodium chloride	Dispersed in 2–3 hr.	Dispersed in 2–3 hr.	Dispersed in 2–3 hr.	No dispersion

flake $(h-h_0)$ to its initial thickness (h_0) over phosphorus pentoxide.

The expansion of the clay in *M* calcium chloride is predominantly intra-crystalline, the d_{001} spacing increasing from 10·0 Å. (over phosphorus pentoxide) to 18·9 Å. In the more dilute calcium chloride solutions the swelling of the untreated clay is due to increasing separation of the clay crystals, as the d_{001} spacing in water is almost unchanged at 19·2 Å. A similar spacing in water has been reported previously[7-9]. As shown in Fig. 1, the inter-crystalline expansion was prevented by the addition of 1 per cent of cetyltrimethyl ammonium bromide or polyvinyl alcohol and largely suppressed by the same quantity of sodium alginate or polyacrylamide. Of these materials, cetyltrimethyl ammonium bromide, an organic cation and polyvinyl alcohol have been found to react with the basal surfaces of montmorillonite, for with increasing concentration they penetrate between the individual silicate sheets forming inter-lamellar complexes[10,11].

The similarity in the swelling pattern of the various complexes suggests that all four materials are reducing the expansion of the clay by linking together the basal surfaces of the clay crystals.

Further information on the nature of the clay–polymer bonds was obtained by trying to replace the exchangeable calcium ions on the clay by sodium ions. Flakes of calcium-montmorillonite with and without 1·0 per cent of polymer added were leached with *N* sodium chloride or 0·15 *M* sodium pyrophosphate adjusted to *p*H 7·0. Afterwards, the behaviour of the flakes was observed in dilute sodium chloride solutions. The results for a range of polymers are given in Table 1. Dispersion of the clay plus polymer flake at the same concentration of sodium chloride as the untreated clay indicates that the polymer has been removed.

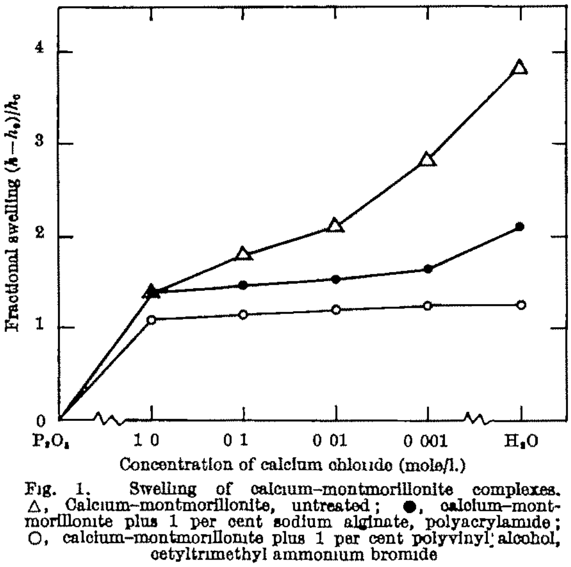

Fig. 1. Swelling of calcium–montmorillonite complexes. △, Calcium–montmorillonite, untreated; ●, calcium–montmorillonite plus 1 per cent sodium alginate, polyacrylamide; ○, calcium–montmorillonite plus 1 per cent polyvinyl alcohol, cetyltrimethyl ammonium bromide

The polymers have been divided into three groups according to their ease of displacement. Polymers of group 1 were readily removed by *N* sodium chloride. This indicates that the complexes were formed by precipitation with the exchangeable calcium ions near the basal surfaces of the clay crystals. The second group was only removed by a strong solution of sodium pyrophosphate. From this, it is inferred that the polymers formed co-ordination compounds with the exchangeable calcium ions, but that these calcium ions could be displaced by a strong sequestering agent. The remaining group of polymers was unaffected by either treatment. Here, the bonding, therefore, is independent of the valency of the exchangeable cation. It is inferred that these polymers are linked by a series of hydrogen bonds between the polymer hydroxyl groups and the surface oxygens of the silicate sheets.

The complex with humic acid extracted from soil is of interest. Previously it has been shown that the clay in soil crumbs from old grassland is still held together after leaching with neutralized sodium pyrophosphate[12]. It follows from the above results that although humic acid can link clay crystals together, it is too easily removed to be the important polymer in soil organic matter for stabilizing soil crumbs.

I wish to thank Dr. K. Norrish for determining the X-ray spacings and Dr. R. Swaby for the sample of humic acid.

Tuesday, May 17

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE (at Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Prof. C. H. Waddington, F.R.S.: "Evolutionary Wisdom and Ethical Value"* (Fourth Auguste Comte Memorial Lecture).

ROYAL AERONAUTICAL SOCIETY, HISTORICAL GROUP (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Sir Thomas Sopwith, C.B.E.: "My First Ten Years" (Inaugural Lecture).

Wednesday, May 18

INSTITUTION OF ELECTRICAL ENGINEERS (at the Institution of Civil Engineers, Great George Street, Westminster, London, S.W.1), at 10 a.m.—Symposium on "Electronic Equipment Reliability—Field Experience and Methods of Assessing and Predicting Reliability".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. F. K. Hare: "The Summer Circulation of the Arctic Stratosphere Below 30 km.", Mr. J. L. P. Jones and Mr. F. Pasquill: "An Experimental System for Directly Recording Statistics of the Intensity of Atmospheric Turbulence"; Mr. J. L. Monteith: "The Reflection of Short-Wave Radiation by Vegetation".

WOMEN'S ENGINEERING SOCIETY (at "Hope House", 45 Great Peter Street, London, S.W.1), at 7 p.m.—Miss R. Winslade: "Electronic Weighing".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. David Lack, F.R.S.: "A Survey of the Conflict Between Evolution Theory and Christian Belief".

Thursday, May 19

INSTITUTION OF MINING AND METALLURGY (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 4 p.m.—Annual General Meeting. Prof. David Williams: "Progress in Mining Geology—Education Research and Employment" (Presidential Address).

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. J. M. Aronson and Prof. R. D. Preston, F.R.S.: "An Electron Microscope and X-ray Analysis of the Walls of Selected Lower Phycomycetes"; Mr. H. G. Callan and Mr. L. Lloyd: "The Lampbrush Chromosomes of Crested Newts *Triturus cristatus* (Laurenti)".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Annual General Meeting, followed by Dr. A. M. Spooner: "Technical Features of a New Television Studio at Wembley".

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Dr. M. J. Lighthill, F.R.S.: "Mathematics and Aeronautics" (48th Wilbur Wright Memorial Lecture).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. G. S. Nelson: "Schistosomes as Zoonoses in Africa".

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 7.30 p.m.—Annual General Meeting. 8 p.m.—Dr. V. E. Cosslett: "X-Ray Microscopy—Retrospect and Prospect" (Thirty-ninth Silvanus Thompson Memorial Lecture).

Friday, May 20

ROYAL SOCIETY OF MEDICINE, EPIDEMIOLOGY AND PREVENTIVE MEDICINE and COMPARATIVE MEDICINE SECTIONS (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Discussion on "Myxomatosis in Britain"., Speakers: Dr. C. H. Andrewes, Mr. H. V. Thompson and the Hon. Miriam Rothschild.

Friday, May 20—Saturday, May 21

BRITISH SOCIETY FOR IMMUNOLOGY (in the Hall of the London Hospital Medical College, Ashfield Street, London, E.1)—Spring Meeting.

Friday, May 20

At 10 a.m.—Symposium on "Immunological Aspects of Diseases of Connective Tissue". Chairman: Dr. L. E. Glynn.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER (with special qualifications in palæontology) IN GEOLOGY—The Secretary, The University, Belfast (May 20).

ASSISTANT LECTURER IN ZOOLOGY—The Registrar, The University, Manchester 13 (May 21).

LECTURER IN THE DEPARTMENT OF NATURAL PHILOSOPHY—The Secretary, The University, Edinburgh (May 21).

EXPERIMENTAL PHYSICIST to work for a D.Phil. degree on high temperature physics, plasma physics, ionization in gases or nuclear gas reactions at very low kinetic energy—T. C. Keeley, Esq., C.B.E., M.A., The Clarendon Laboratory, The University, Parks Road, Oxford (May 21).

READERS IN NUCLEAR PHYSICS; MATHEMATICS (preferably Mathematical Physics); MATHEMATICS (Electronic Digital Computers); and CHEMICAL ENGINEERING—The Bursar, College of Advanced Technology, Gosta Green, Birmingham 4, quoting "D" (May 21).

LECTURER (Grade II) IN STATISTICS within the Department of Mathematics—The Registrar, The University, Bristol (May 23).

READER (with outstanding research ability) IN PHYSICS; a SENIOR LECTURER (with a good honours degree together with research and/or industrial experience, and preferably an interest in nuclear physics) IN PHYSICS; and an ASSISTANT LECTURER, Grade "B" (with a good honours degree) IN PHYSICS—The Registrar, Royal Technical College, Salford 5, Lancs (May 23).

TECHNICAL OFFICER (with a specialized knowledge of optical design and appropriate experience, and preferably mathematics and physics to G.C.E. "O" level) IN OPTICAL DESIGN, at the Weapons Research Establishment, Salisbury, South Australia, to be responsible for the design of optical lenses and systems, under the general guidance of the professional staff—Senior Representative (AV. 60/3), Department of Supply, Australia House, Strand, London, W.C.2 (May 23).

INSTRUMENT TECHNICIAN (Experimental Officer grade, with H.N.C. or equivalent), for the development, adaptation and maintenance of instruments used by research departments—The Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex (May 24).

KEEPER IN BOTANY (with a good honours degree in botany and/or a Museums Diploma, and preferably museum experience)—The Director, Liverpool Public Museums, Carnatic Hall, Elmswood Road, Liverpool 18 (May 24).

LECTURER, Grade II, IN CHEMICAL PHYSIOLOGY—The Registrar and Secretary, The University, Bristol (May 24).

NEMATOLOGIST; and a GENETICIST (Plant Breeder) (Scientific Officer grade, with an honours degree in an appropriate scientific subject, and preferably postgraduate experience)—The Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex (May 24).

ASSISTANT EXPERIMENTAL OFFICER (graduate, with a degree in zoology and/or botany and an interest in biochemistry, also those graduating in 1960 considered) IN THE NEMATOLOGY DEPARTMENT—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (May 28).

ASSISTANT LECTURER IN PHILOSOPHY—The Registrar, University College of Wales, Aberystwyth (May 30).

ASSISTANT LECTURER (preferably with a special interest in inorganic chemistry) IN CHEMISTRY—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (May 30).

ASSISTANT LECTURERS (2) IN PHYSICS—The Principal, Royal Holloway College, Englefield Green, Surrey (May 31).

CHAIR OF BOTANY—Joint Clerk to the University Court, The University, St. Andrews (May 31).

FELLOW, for research on factors influencing flowering and seed production in herbage grasses—The Registrar (Room 22, O.R.B.), The University, Reading (May 31).

LECTURER or SENIOR LECTURER IN GENETICS AND PLANT BREEDING; an ASSISTANT LECTURER IN BOTANY; and a DEMONSTRATOR IN ZOOLOGY in the Department of Biological Sciences—The Registrar, Wye College (University of London), near Ashford, Kent (May 31).

RESEARCH ASSISTANT (preferably candidate with either a degree in geology with good subsidiary zoology or a good degree in zoology with subsidiary geology) IN VERTEBRATE PALÆONTOLOGY IN THE DEPARTMENT OF GEOLOGY—The Registrar, King's College (University of Durham), Newcastle upon Tyne 1 (May 31).

ESSO RESEARCH FELLOW IN PHYSICAL CHEMISTRY, to work in the field of heterogeneous catalysis—The Registrar, The University, Nottingham (June 1).

RESEARCH FELLOW (post-doctoral chemist or biochemist) IN THE DEPARTMENT OF CHEMISTRY of the Faculty of Science, to take part in work on the synthesis of nucleotide analogues and the study of their metabolism—The Registrar, The University, Manchester (June 1).

ASSISTANT DIRECTOR OF GRADUATE STUDIES IN THE DEPARTMENT OF PHYSICAL CHEMISTRY—The Registrar, The University, Leeds 2 (June 7).

ASSISTANT LECTURER or LECTURER (with special qualifications in pure mathematics) IN MATHEMATICS—The Registrar (Room 22, O.R.B.), The University, Reading (June 7).

BOTANIST, Scientific Officer grade (with a good honours degree and preferably postgraduate training or research experience), to study the development and anatomy of apples in relation to storage behaviour—The Secretary, East Malling Research Station, near Maidstone, Kent (June 11).

PLANT PHYSIOLOGIST (honours graduate in science or agricultural science with appropriate postgraduate research experience) IN THE DIVISION OF PLANT INDUSTRY, Commonwealth Scientific and Industrial Research Organization, Canberra, A.C.T., Australia, to initiate studies on the physiology of growth in pastures and pasture plants with the ultimate aim of understanding more fully the determination of pasture yield—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 130/418 (June 11).

Senior Lecturer (with research experience) in Physiology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 11).

Associate Professor in Mathematics; a Senior Lecturer or Lecturer in Mathematics; a Senior Lecturer or Lecturer in Statistics; a Senior Lecturer or Lecturer in Botany; a Senior Lecturer or Lecturer in Chemistry; a Senior Lecturer or Lecturer in Geology; a Senior Lecturer or Lecturer in Physics; and a Senior Lecturer or Lecturer in Zoology at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 15).

Lecturer (graduate in science, preferably with honours in physiology, or with a higher degree, or graduate in medicine or veterinary science, and preferably with experience in research in, or teaching of, physiology) in Physiology at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 15).

Lecturer in the Department of Chemical Engineering, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, June 15).

Senior Lecturer in Physics; Lecturers (2) in Chemistry; a Lecturer in Civil Engineering; and Lecturers (2) in Mathematics at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, June 15).

Lecturer and a Senior Lecturer in Applied Mathematics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 18).

Lecturer (honours graduate in either physics or electrical engineering, and preferably with an interest in audiofrequency acoustics associated with human communication) in Acoustics in the Department of Physics—The Registrar, The University, Liverpool, quoting Ref. No. CV/N (June 18).

Senior Lecturer or Lecturer in Physics at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, June 18).

Lecturer (qualified and interested in any of the following research topics: solid state studies, X-ray spectrography of solids and gases, radio investigations of the upper atmosphere such as meteorite distribution, auroral zone detection and studies of the lower ionosphere); and an Assistant Lecturer (with an honours degree in physics) in the Department of Physics, University of Canterbury, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, June 30).

Senior Technician in the Department of Physiology; and a Scientific Instrument Mechanic, to take charge of the Faculty of Science Workshop, Makerere College, The University College of East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 30).

Mental Health Research Fund Fellows (suitably qualified persons wishing to pursue full-time research work bearing on problems of mental health, whether in clinical psychiatry, or one of its supporting sciences)—The Secretary, Research Committee, Mental Health Research Fund, 39 Queen Anne Street, London, W.1 (October 1).

Biochemist, Basic grade (graduate in chemistry or Associate or Graduate Member of the Royal Institute of Chemistry), in the Department of Pathology—The Group Secretary, Queen Elizabeth Hospital for Children, Hackney Road, London, E.2.

Biochemist, or an Organic or Physical Chemist (university graduate with first- or second-class honours), to work at Millport on organic matter in sea water in its relation to marine organisms—The Director, Scottish Marine Biological Association, Marine Station, Millport, Isle of Cumbrae, Scotland.

Biochemist (Senior or Basic grade), to the Rochdale Group of Hospitals, to work under the Consultant Pathologist and to carry out biochemical work for the hospitals and clinics of the Group—The Group Secretary, Rochdale and District Hospital Management Committee, Central Offices, Birch Hill Hospital, Rochdale, Lancs

Head (medical graduate or science graduate with a higher degree) of the Division of Virology, for duties which will include the supervision of diagnostic services and the carrying out of special investigations on, and research into, virus diseases—The Director, Institute of Medical and Veterinary Science, P.O. Box 14, Rundle Street, Adelaide, South Australia.

Lecturer (male, single, preferably specializing in entomology and/or animal physiology) in Agricultural Zoology and Assistant Warden—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, near Chelmsford.

Lecturer (with a good honours degree in mathematics with teaching and/or industrial and research experience) in Mathematics—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex.

Research Assistant (man or woman) in Zoology, to assist Prof. T. A. Stephenson, F.R.S., with the completion of a book on the seashore ecology of the world—The Registrar, University College of Wales, Aberystwyth.

Senior Lecturer and a Lecturer (with an honours degree in physics, industrial and/or research experience in some branch of applied physics, and teaching experience) in the Department of Physics—The Registrar, College of Science and Technology, Ashley Down, Bristol 7.

Senior Technician or Technician for duty in the Clinical Isotope Laboratory—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

Technical Editor (preferably with a pass degree, H.N.C., or equivalent qualification, and appropriate experience in a related field of work), to be employed on editing, proof-reading, indexing and distribution of scientific reports, technical specifications, etc., and the handling of information inquiries relating thereto—The Senior Recruitment Officer, United Kingdom Atomic Energy Authority, A.W.R.E., Aldermaston, Berks, quoting Ref. No. A.2493/34.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Genetical Research, Vol. 1, No. 1 (February 1960). Pp. 172+5 plates. Published in February, July and November. Subscription rate: 100*s.* net (including postage) for an annual volume of three parts (17.50 dollars, U.S.A.). Separate parts 40*s.* or 7 dollars (plus postage). (London and New York: Cambridge University Press, 1960.) [252

Bulletin of the British Museum (Natural History). Zoology. Vol. 6, No. 2: A Revision of the Platyseiinae (Mesostigmata: Aceosejidae) based on Material in the Collections of the British Museum (Natural History). Pp. 25–101. (London: British Museum (Natural History), 1960.) 24*s.* [252

Liverpool Observatory and Tidal Institute. Annual Report, 1959. Pp. 19. (Liverpool: Liverpool Observatory and Tidal Institute, 1960.) [252

EDUCATION AND THE YOUTH OF GREAT BRITAIN

THE debates on the Crowther Report, in the House of Commons on March 21 and in the House of Lords on March 23, were noteworthy for the statements of Government policy made by the Minister of Education and the Minister for Science, although the Government had already indicated its acceptance in principle of the recommendations both of the Crowther Report and of the Albemarle Report on the youth service in England and Wales. The debates, moreover, brought out the way in which, to some extent, the recommendations of the two reports are interlocked; and, particularly in conjunction with earlier debates in the House of Lords on the problems and opportunities of leisure, on March 2, and on adult education, on March 16, they also helped to clarify a number of the main issues involved and the points at which action is imperative. Moreover, appropriate action is not solely the responsibility of the Government; speaking in the debate of March 2, Lord Hailsham, referring to the acceptance of those recommendations of the Albemarle Report which require Government action, said that the Government would as soon as possible be discussing with the local education authorities the part they should play, and that the Minister of Education desired him to lay great stress on the need for voluntary effort.

So far as leisure is concerned, Lord Hailsham himself believes that the vital role of education is in the inculcation of right standards, and that here the critical battleground is in the home, with the school as an invaluable ally. In this he thinks the technical colleges as well as the schools have an important part to play: full-time education gives the best opportunity of instruction in the art of using leisure, and the key place now occupied by scientists and technologists in modern life makes it imperative to seek to increase their awareness of the economic and social importance of their work. Here Lord Hailsham referred incidentally to the value of educational research—a topic that received a remarkable amount of attention in the later debates on the Crowther Report. For the rest, however, on this occasion Lord Hailsham was concerned to stress the limitations placed on Government initiative in a free society if the use by the individual of his faculties is to be encouraged and not undermined.

While the Crowther Report and its recommendations have already been discussed in these columns, beyond the general acceptance of these recommendations in principle little was known of the Government's intentions. These have been made much clearer by Sir David Eccles's speech on March 21, in asking the House of Commons to welcome the Report. Sir David said at once that the Government accepts its major recommendation that the school-leaving age should be raised to sixteen provided the extra year in full-time education can be spent either in school or in a technical college, but he questioned the desirability of fixing the date now before we have ensured that the necessary conditions can be fulfilled, particularly as there is already a strong tendency for more children voluntarily to stay on after the age of fifteen.

The four pre-conditions specified by Sir David are, first, school buildings adequate to accommodate the extra pupils; competence to hold the interest of the 15–16-year-olds; sufficient teachers; and a public opinion which fully supports this step. As regards the first, he believes that if the resources were made available, we could provide the total building requirement of about £80 million for England and Wales in four years before the date suggested for raising the age. In many secondary schools the teaching staff has not yet had a fair chance to provide satisfying courses for the *C* and *D* streams in their last year, and while the Crowther Council is confident that the schools could be so much improved by the late 1960's that Government need not be afraid to name the date now, Sir David said that the public reaction to the Report indicates great misgivings about doing so now.

Dealing more fully with the question of teachers, which he regards as the heart of the problem, Sir David said that about 18,000 teachers would be needed to raise the school-leaving age; but before we can spare these teachers, we must reduce the number of over-size classes and so give the teachers in them the chance of doing their job really well. No other single reform, in his opinion, would so raise the standard of education in Britain. Four factors have postponed the removal of this handicap to good teaching: the unexpected increases in the birth-rate; the very welcome increase in numbers of those voluntarily staying at school beyond the age of fifteen; a considerably greater wastage of teachers than was expected; and the introduction of the three-year training course for teachers in place of the two-year course. This last reform, the only factor under Government control, involves the loss in 1962 of more than 10,000 new teachers coming from the training colleges, and because of it, while agreeing with the Crowther Committee that one or at most two leaving dates during the year would be sound educationally, Sir David said that because of the employment implications, he would be discussing that aspect with the Minister of Labour and others concerned before reporting to the House the Government's conclusions.

As regards the actual supply of teachers, Sir David Eccles said that the output of teachers from the 39,000 places in the training colleges could not exceed 13,000 a year if over-crowding is to be avoided and reasonable provision reserved for overseas students. The Government has accepted in principle the recommendation in the Crowther Report to add a further 8,000 places, but Sir David could not say how soon this could be achieved; if all went well, he thought by 1970 that over-size classes could be eliminated and at the same time the school-leaving age raised. Dealing next with the introduction of county colleges, he said that the Government agrees with the Crowther Committee that the raising of the school-leaving age should come first for three basic reasons stated in its Report. Nevertheless, the Government intends to press on with the voluntary further education of the sixteen- and seventeen-year-olds, and he believes that the technical college programme, which has progressed so much in the past three or four years, provides the opportunities for a big advance. First, the 300 local colleges, well spaced in England and Wales, a few of which are already running courses of the county college type, form a natural focus for the development of county college work. Secondly, as the Parliamentary Secretary to the Ministry, Mr. K. Thompson, said in replying on the debate, the Ministry has plans for much-improved arrangements for courses in technical colleges to expand further education on a voluntary basis. Some 400 projects have been authorized for the establishment of new colleges or the improvement of existing colleges.

Sir David did not refer to one important point made in the Crowther Report regarding the staff of the sixth form in schools—the fact that the schools have not yet experienced anything like the full effects of the decline in the quality of recruitment in recent years, nor did other speakers in the debate refer to the serious risk of a still worse crisis in science-teaching as the older men and women retire. Besides, however, touching on the question of finance, Sir David concluded by emphasizing two other important matters, both of which were also stressed by Lord Hailsham. As regards finance, Sir David estimates that, making no allowance for any of the Crowther recommendations, the annual cost of education for England and Wales would have risen from the present £700 million by one half by the end of the decade, and by four-fifths in the middle 1970's. Nevertheless, the Government believes it right to find this £1,400 or £1,500 million a year for education, even if it means sacrifices in other directions.

The first of Sir David's two points is that of educational research. The Crowther Committee commented that the present expenditure on educational research, in view of the large annual expenditure on education, can only be regarded as pitiable, and that if there is to be a consistent programme of educational development, almost the first step should be to review the provision for statistics and research. Sir David had referred to some specific examples where more information is needed before stating that action is already being taken to increase the amount of such research undertaken by the Ministry and to strengthen its statistical services; this action was warmly welcomed by several speakers in the debate, notably Mr. I. J. Pitman, Mr. F. Blackburn and Sir Hubert Ashton.

Lord Hailsham did not touch on this question of research in his speech in the House of Lords on March 23, but generally he followed the line taken by Sir David Eccles. Even more explicitly, he gave first priority to the elimination of over-size classes, which he thought should be possible by the end of the present decade; and in referring to the plans for more teachers, he urged that the number of graduates among teachers should be substantially increased. He also referred particularly to the provision of graduate teachers of science and mathematics. To maintain 1959 staffing standards in 1970, we shall need to increase the present 12,800 graduates in science by about 400 a year net, and ideally we should at least double the average net annual increase; though Lord Hailsham does not think we are likely to achieve this even with the proposed expansion of the universities and a significant contribution from the training colleges, where a number of specialist science wings have been attached to general colleges with a capacity of about 1,200 places. The four hundred science specialists expected from these wings should provide an invaluable supply of teachers to the schools, especially those with General Certificate of Education 'Ordinary' Level courses which at present employ 3,250 non-graduate science teachers. In March 1959 there were 5,100 mathematics graduates and 7,700 science graduates teaching senior pupils in maintained schools; but at the end of 1958 there were 505 such posts vacant and another 509 were said to be unsatisfactorily filled.

On finance, Lord Hailsham reiterated his view that we should spend at least 5 per cent of the gross national product on education. He also pointed out that even without the 8,000 additional places in teacher-training colleges, the cost of education in Britain will rise to £1,000 million by 1964, and with university education will then be more than 5 per cent of the estimated gross national product. He reminded the House that education will be in competition with claims on the national income from roads, railways, pensions and National Health Service, for example, and that it is imperative that investment in factories, transport, machinery and laboratories should keep pace with educational advance. He admitted that it is a great weakness in the educational system of Britain that so many children go out of full-time education at fifteen, but he emphasized the importance of first making sure that the curriculum is suitable to the needs of those who are thus compelled to remain at school.

Apart from a passing reference at this point to the county colleges and the experiment proceeding in some local colleges of further education, the most important remaining passages in Lord Hailsham's speech were those which took up the comment in the Crowther Report on the absence of any single body within the United Kingdom which looks at school and university education as a whole, and in which he urged that the schools and universities should come closer together. Sir David Eccles had already touched on this in referring to university entrance and to the helpful response he had had from the Committee of Vice-Chancellors and Principals, who, he said, are fully alive to the need for more university places to be available and the conditions of entrance to be modified to enable sixth-form teachers to find time to teach English thoroughly, and to provide more science for the arts specialists and more of the arts to the scientists.

On the question of university places, Sir David said that the University Grants Committee has already been authorized to discuss with the universities a further expansion of 35,000 to 40,000 places by about 1970 over and above the present target of 135,000 to be available by the late 1960's. Lord Hailsham commented that not long ago strong exception would have been taken to the Minister of Education showing such interest in the universities. He welcomed the change, and what Sir David had affirmed that these problems of university entrance, over-specialization and reform of the curriculum are now being vigorously attacked in concert by the universities, the schools and the Ministry. During the debate, Lord James of Rusholme urged that the raising of the school age is not so much a question of an extra school year as of an opportunity to provide a genuine course of secondary education, and has also both the importance of sixth-form work and the danger of over-emphasizing the gulf between science and human knowledge. In replying on the debate, Lord Hailsham dealt with what is probably the most vital issue in regard to the fixing of a date for raising the school-leaving age. He did not dispute the value of this step or deny the plea for timing which Lord James had reiterated. Conceding, however, the Crowther Committee's conclusion that the necessary measures should be worked out and adopted as a coherent, properly phased development programme, extending over as much as twenty years, it remains true, as Lord Hailsham pointed out, that we are dealing with parents and children who do not share that view as to the value of education after the age of fifteen. It is not simply a question of buildings and the supply of teachers or the development of appropriate curriculum, but of at what stage and in what circumstances we are to apply the principle of compulsion not only to laggards but also to a minority of children whose formal education might well have ceased at fourteen or even earlier.

There is, of course, a further point implicit in a speech of Mr. C. Curran in the House of Commons debate, in which he urged the raising of the school-leaving age to sixteen on the grounds of the social value of taking children of fifteen off the labour market as soon as we can, so as to deny the purchasing power largely responsible for many juvenile problems. From both aspects this question of an additional school year is related to the problem of leisure and to the development of youth services, and it should be clear that any phased programme of educational development in Britain must take account in its timing and other aspects of what is being done to meet the needs of youth generally and to deal with the problems of leisure. That much was indeed recognized by the Albemarle Committee itself; but Sir Geoffrey Crowther, in a speech in Manchester on March 22, challenged the idea of absolute priorities, and with regard to county colleges pressed the need for considerable experience before we commit ourselves to compulsory attendance. It may well be that ultimately the broad advance for which the Albemarle Report calls, and a generous return for the money expended on the youth service, will result from the effect of educational progress generally; it will also depend on the creation of an appropriate public opinion and the impetus given to the supply of teachers and youth leaders of high quality and clear vision and the professional ability to use to the full the opportunities which are now opening to them.

MANAGEMENT OF RESEARCH PERSONNEL

The Human Element In Research Management
By Dr. B. E. Noltingk. Pp. vii+91. (Amsterdam: Elsevier Publishing Company; London: D. Van Nostrand Company, Ltd., 1959.) 9*s*. 6*d*.

I FOUND the title of this book somewhat misleading. It is really a book about research personnel management, rather than about the more restricted conception of the use of the word 'human'. It has chapters on scientists themselves, anatomy of a laboratory, physiology of a laboratory, seniors, juniors, strategy, output and ethics, but does not, for example, deal at any great length with the hopes and aspirations of research scientists, and does not attempt to analyse their motivations.

Despite the author's rather disarming statement in his preface of what "prompts me to the conceit of writing a book without many years' opportunities to put all its precepts into practice", I was left with the feeling that some greater experience on the part of the author and a deeper study of the existing literature on his subject might, when coupled with his own views, have produced a book of deeper significance. For example, the author gives some reasons for not having made himself familiar with all the published work in his field before venturing into print, but the works to which he does refer are, in the main, articles in journals the main interests of which lie in somewhat different directions, and which are summaries rather than the results of systematic observation and investigation.

I am, perhaps, somewhat biased on this matter because I am writing this review in the United States, where there is a considerable literature on Dr. Noltingk's subject. Much that has been written in the United States on this subject might never have achieved publication in Great Britain, but for all that the subject has received considerable systematic study, and the author should, I think, have shown that he was aware of this. This does not mean that on the whole I disagree with the author's views, but they are rather naive, and because his experience would appear to have been rather limited, he has not produced anything particularly novel.

The book is well written, and the biblical quotations at the chapter headings are apt. Dr. Noltingk does well, in my view, to stress greatly the importance of asking the right questions concerning research. Most of his generalized conclusions would be agreed by many research scientists who have had to give at least part of their attention to the organization and control of the work of others.

Some of the author's statements are, however, not in accord with past experience. For example, in dealing with the problem of the older scientist he states that if such an individual's project has perforce to be stopped, moving him outside the laboratory may well be the soundest policy. He then makes the common error of suggesting that perhaps laboratory administration is a good outlet for him. He goes on to say that "it is doubtful whether a deficiency of several years' experience could ever be remedied to fit him for the role of a senior scientist in a different field". For many scientists this may be true, but certainly for many more it is true that they can enter entirely new fields effectively and successfully, and experience during the Second World War showed that scientists could do first-class research in disciplines entirely different from those in which all their previous experience lay. I am one of those who believe that very few scientists are dedicated, in the sense that they can do effective work only in one field. I know from experience that some people with first-class paper qualifications will probably never do any effective original work in any field, but for the great majority of scientists I believe that a good man will be good in whatever he tackles.

In dealing with salaries, the author suggests that a time might arrive when "the man in authority could sometimes actually be paid less than those under him". This position has existed for many years in many large research organizations, if one accepts 'under' as meaning 'organizationally under'. In many research organizations in Great Britain and in the United States there are two avenues of promotion, one organizational and the other depending purely on scientific ability with no significant organizational responsibilities. The 'special merit' promotions in the Scientific Civil Service in Britain and the wide use of 'consultants' in the United States are examples of this.

In dealing with periodical reviews of staff for promotion, the author comes to the conclusion that "the simple solution of leaving him to be assessed by the boss, who will apportion accordingly the money he has available, is the best". This is a system which may work in a small organization, but concerning which there are very great difficulties where large numbers of staff have to be considered. Various bosses have various standards, and in any organization, if good staff relations are to be maintained, there must be reasonably common standards throughout it. Some systemization must therefore be attempted unless all the staff can be judged by one individual, and even then my experience is that the majority of junior staff dislike such a system. They feel that their careers depend too much on the whim of an individual, and that whether they get promotion or not may be almost fortuitous. The larger the organization the more this appears to be felt, and it is often not realized that in large organizations, such as the Civil Service, much of the apparent 'red tape', and even much of the apparent inflexibility, derives not from the wishes of the top people, but from the pressures from below. The era of 'the boss can't be wrong' has passed, and although all matters of advancement must to a great extent be the result of subjective assessment by others, modern systems can reduce considerably the element of chance.

In dealing with what he calls the physiology of the laboratory, Dr. Noltingk comes to the conclusion that it should not have a larger staff than about 300 if it is truly to be directed by one man. He thinks that if it is larger than this, then the divisional heads will become virtually directors of separate units. This is probably true, although there are many examples of larger organizations being directed by one man if the organization has grown up under him. On the other hand, it is a little doubtful whether one man can become director of an existing laboratory, even of the 300 size, and be effectively the director of the science as well as the director of the institution, but here much will depend on the nature—not the discipline—of the work. Very much larger organizations can be directed by one man if they are what the Americans call 'uni-purpose', that is to say if they have a convergent structure, and this is particularly the case when the scientific work is applied rather than fundamental. The size of the organization which can be directed by one man becomes much less when the organization is multi-purpose or divergent, that is to say where there is no close relationship between the objectives of the various subjects studied.

In one matter I cannot agree with Dr. Noltingk. In several chapters in the book he mentions the need for a laboratory to advertize its existence: for example, in one chapter he says, ". . . for research laboratories in the modern world, like detergents or beer, need to keep themselves in the public eye not so much by reasoned argument of their excellence as by frequent reminders of their existence". In a further chapter on output he again says about a laboratory, "A proportion of its activities should quite openly and admittedly be devoted to blowing its own trumpet, and betterment of the regard in which it is held should be recognized as part of its desired output".

Something of this sort may be necessary in the organization of which a laboratory is part, but I would have thought that the general principle of 'good wine needs no bush' applies very much to scientific research establishments. If they do good work they will become well known, and however large they are and whatever their publicity policy, unless they do good work their reputation will suffer. I particularly, therefore, disagree with the author when he says of a laboratory director, ". . . the need to approach problems scientifically should be, with the praises of his own laboratory, the twin stanzas of his signature tune". E. S. Hiscocks

MAYA HIEROGLYPHICS

Maya Hieroglyphic Writing

An introduction. By J. Eric S. Thompson. Second edition. Pp. xxii+347+64 figures. (Norman, Oklahoma: University of Oklahoma Press, 1960.) 10 dollars.

When this book first appeared in 1950 as one of the publications of the Carnegie Institution of Washington it was thought that it was only for specialists, but it was written with such a background of knowledge of the Maya, both those who survive and those long dead, that it has had a far wider appeal. It has been out of print for some time and the demand for it has proved so great that this new edition has been issued by the University of Oklahoma Press. Apart from a short preface reviewing progress since 1950, it is a facsimile reproduction of the first edition, with the welcome addition of a substantial binding. Experience has shown that a word of explanation about the title of this massive work will not come amiss; far from being a mere introduction to Maya hieroglyphics, it is a very profound study of this difficult subject, but it was also designed to introduce a dictionary of non-calendrical glyphs, a work which the author has only just finished. Eric Thompson has studied the Maya for the past thirty years or so, and has long been known as one of the foremost authorities on their hieroglyphic writing. This book has added greatly to his reputation.

It contains a wealth of detailed information about the various types of Maya inscription, those cut in wood and stone, and those painted in the manuscripts and to a lesser extent on wall or pot. Each of the great synchronized cycles which make up the calendar is considered, and new light is thrown on divinatory inscriptions. All this reveals the staggering complexity of the subject; but the treatment is lightened by the author's constant insistence on human and spiritual factors and by the happiness of his style. He says in effect that mathematics and astronomy have an essential part in this study, but that an understanding of Maya religion and mythology is as important, and he goes so far as to say that "Mysticism, religion and poetry completely dominate their hieroglyphic writing." It is emphasized that the whole of Maya religion revolved around the majestic conception of the eternal march of time, in which the periods into which the calendar is divided are borne along by the gods, who pause only to change their burdens over like relay runners at the appropriate period endings. This is graphically shown on the most elaborate form of inscription, the full-figure glyphs exemplified by Stela *D* at Copan, of which a free modern version forms the frontispiece.

The brevity of this notice is not a measure of the importance of the book, which is unsurpassed in its own field, but of the small number of those who concern themselves with the study of the Maya in Great Britain. It is pleasant to record that the author himself has returned to swell their number after living for many years in the New World, and it is to be hoped that his new Glyphic Dictionary will soon be published. G. H. S. BUSHNELL

WORLD DISTRIBUTION OF ABO BLOOD GROUPS

The ABO Blood Groups

Comprehensive Tables and Maps of World Distribution. By Dr. A. E. Mourant, Ada C. Kopeć and Kazimiera Domaniewska-Sobczak. (Occasional Publication No. 13 of the Royal Anthropological Institute.) Pp. viii+276. (Oxford: Blackwell Scientific Publications; Springfield, Ill.: Charles C. Thomas, Publisher, 1958.) 42*s*. net.

DR. MOURANT and his colleagues have brought together all the results published up to the end of 1957 on the frequency of the ABO blood groups in the human population; the figures are given for the majority of areas in the world. The result is a most comprehensive book on the distribution of these groups incorporating 1,056 references and 6 maps.

After a short introduction, the information is given in the form of tables. These show place, population, authors and numbers of samples examined, the frequencies of each of the groups, the calculated gene-frequency and, in the last column, the figure D/σ. The vast bulk of the material has been published in the form of the groups O, A, B, and AB, but there are sections where the sub-groups of A have been wholly, or partially, classified. The authors say that "the classification adopted for the data is primarily topographical"; both place and population are well covered, and the population column includes racial or tribal names where appropriate.

In the largest section of the work, the gene-frequencies have been calculated according to Bernstein's formula, but in the section where the sub-groups of A are completely classified the maximum likelihood method is used. The figure D/σ in the last column is given in preference to the usual χ^2; it is a measure of the deficiency or excess of the group AB in the results as compared with the calculated frequency. The authors consider that this value allows the reader to make his own estimate of the reliability of the results with respect to genetical homogeneity or accuracy of testing. It is unfortunate that the authors did not write a more comprehensive introduction, giving details of the statistical calculations and more details of the factors which affect the value of D/σ, with a discourse upon the interpretation of the results; for the average reader this would have been most helpful. The claim of the authors that this single figure gives a general indication of the reliability of the results is probably valid, but others might well have need to consult the original paper to obtain an accurate estimate of a particular work.

The book is an excellent reference book, with good typography. It is easy to read and the tables are set out (and the book opened) in the long way, which makes them easy to see; but the book is not so easy to fit into a bookcase. To have all this information available in such a small compass is, indeed, valuable for all who are concerned with blood groups, whether they are hæmatologists, anthropologists or geneticists. Dr. Mourant and his colleagues are to be congratulated on the production of this extremely comprehensive and unique work. F. STRATTON

FACTORS AND CAUSES OF INFECTIVE DISEASES

The Aetiology of Infective Diseases

With Special Reference to the Subsidiary and Important Non-specific Factors. By Prof. Reginald Lovell. Pp. viii+136. (London: Angus and Robertson, Ltd., 1958.) 27*s*. 6*d*.

IN this book Prof. Lovell, whose experience and authority are well known, gives us the substance of lectures which he delivered in the Department of Microbiology and Public Health at Michigan State University in 1955. He intends the book to stimulate rather than to instruct, and hopes it will awaken interest in the philosophy of epidemiology; both of the aims are certainly achieved. Much knowledge of fact is also added in the author's clear and persuasive style. Though the text refers largely to diseases of domesticated and other animals, the relationship between these and the diseases of man is well brought out.

The book begins by pointing out that the nature of disease is always changing and that this constant change is part of our social history. An infective disease, once it is established, Prof. Lovell reminds us, may stay with us for good and he gives us evidence of this. Discussing next the normal bacterial flora of man and other animals, and the phenomena of resistance (immunity) to disease, he goes on to discuss the host-parasite relationship, which, like disease, is never stable, a fact which is, in spite of Lovell's view to the contrary, very well realized nowadays.

In Part 2 of the book the author discusses various subsidiary factors which play a part in infective disease. Thus the influence of age is illustrated by reference to white scours of calves, infantile diarrhœa, lamb dysentery, Johne's disease of cattle, meningitis in children, diphtheria, scarlet fever, leptospiral infections and various viral diseases, including poliomyelitis. The significance of sex is illustrated by reference to mastitis and pyelonephritis of cattle, trichomoniasis, tuberculosis, brucellosis and other infections. The effects of changes in the host's diet are illustrated by reference to botulism, food poisoning by *Salmonella*, enterotoxæmia of lambs and protein deficiencies and those due to changes in husbandry and environment, by tuberculosis, the slow pneumonia of sheep in Iceland called 'maedi' and by Johne's disease of cattle and braxy of sheep. Fungal infections are considered under the heading of the effects of the general health of the host. In an interesting section on the effects of trauma the author discusses tetanus, gas gangrene and infections with various species of *Clostridium* and those due to the bites of animals, such as rabies. The effects of stress and fatigue and the use of properdin and adrenocorticoids for the treatment of them are then considered, and a final section discusses infections which involve a living vector as well as a pathogen, the diseases here discussed including rickettsial and viral infections, influenza of man and swine, louping ill, foot and mouth disease, yellow fever, psittacosis, *Q* fever, distemper of dogs and the different distemper of cats and other infections. A brief bibliography gives references to standard works.

Both the veterinarian and the student of human disease will learn much from this book, and it will, as its author commendably intends, make him discard any tendency he may have to think of each disease as a separate entity. G. LAPAGE

A TREATISE ON STATICALLY INDETERMINATE STRUCTURES

Hyperstatic Structures

An Introduction to the Theory of Statically Indeterminate Structures, Vol. 1. By Prof. J. A. L. Matheson. With chapters by Dr. N. W. Murray and Dr. R. K. Livesley. Pp. xv+474. (London: Butterworths Scientific Publications, 1959.) 90*s*.

THE student of that branch of elasticity which deals with structural mechanics too often finds himself confused by the numerous 'theorems' and 'principles' which so liberally ornament the literature of the subject. This confusion is worse confounded by the use of various names for the same result, and even, on occasion, the appropriation of a well-established designation for something quite different.

In fact the number of independent principles which are of value to the engineer are surprisingly small, and even if the subject is approached from a purely academic point of view rather than from a more practical one, that number is not greatly increased. Many of the results which are so frequently stated as principles are in fact variations, often obvious ones, of fundamental theorems. These variations may, indeed, prove very useful in particular applications, but their isolation from the fundamentals on which they are based makes for an artificial elaboration of the subject and the consequent bedevilment of the student.

One of the avowed objects of the author of this book is to clarify this position and to show the inter-relationship of the many theorems and methods commonly quoted. The result will be of considerable interest to the reader who already has a working knowledge of the subject; but the word 'introduction' in the title may prove somewhat misleading and even disheartening to the real beginner.

In the preface the author says that the book is an attempt to produce the treatise (incidentally a much better description of the work than is indicated by the title) which his friends hoped that the late Prof. Cyril Batho would write. Batho had an extensive knowledge of German literature on theory of structures and a great admiration for the work of Mueller-Breslau in particular, and his friends will be in no doubt that he would have been pleased by Prof. Matheson's treatment. This comment, however, does only partial justice to Matheson; in addition to the careful presentation of the classical work of Clerk Maxwell, Mohr, Castigliano, Williot and Mueller-Breslau there is much which could not have been found in a book by Batho, for even in the few years since his death considerable advances have been made. References to the work of David Williams, E. H. Brown and others in clarifying the relationship between the different energy theorems, and the specialized chapters on the stability of struts and frameworks, and on matrix methods of analysis, by N. W. Murray and R. K. Livesley respectively, indicate the up-to-date character of the book.

In this connexion, too, the inclusion of a short account of the work of Prof. J. F. Baker and his colleagues at Cambridge is to be welcomed as an outline of the latest trends in steel structural design based on collapse loads; the possibility suggested by the author that this reference may be out of place in a work dealing with elastic structures surely need not be considered seriously. Elastic and plastic behaviour are both phenomena with which the engineer has to deal, and any attempt at a complete separation of their study can only lead to an unbalanced outlook.

A suggestion for future editions which might be offered is that the section of Chapter 1 which deals with intuitive methods for the approximate solution of statically indeterminate problems should be relegated to an appendix. It is undoubtedly true that a visualization of displacements can materially assist the analysis of a structure, but it is equally true that intuition can come only as a result of experience and knowledge, and to suggest some of the ideas contained in this section at such an early stage may prove a disservice to the student rather than a help.

The book is excellently produced, and with its companion volume of examples which is promised for a later date will add something distinctive to British literature in theory of structures. One wishes it the success which it merits. A. J. S. PIPPARD

A Guide-Book to Biochemistry

By Kenneth Harrison. Pp. viii+150. (Cambridge: At the University Press, 1959.) Cloth edition, 17*s*. 6*d*. net; Paper edition, 10*s*. 6*d*. net.

THERE are several good modern biochemistry books in the thousand-page category, but there is a real need for the introductory type of book of a hundred pages or so. Biochemistry has grown into such a vast subject that an author who is courageous enough to write a small book about it is sure to be criticized for what he decides to leave out, if not for what he puts in. The decision will, of course, depend on the type of reader the author has in mind. According to the dust cover (for which the author may not be responsible), this book is aimed not only at science students at the university, but also at boys and girls at school who may be thinking of taking up biochemistry later on. What will these potential biochemists find in the book? After a short introduction they will find chapters on energy, oxidation (including several pages on the *r*H scale), photosynthesis, metabolism of carbohydrates, fats and proteins, and a final chapter on control of metabolism. For good measure they will be able, in an appendix, to study the full structural formulæ of complex molecules such as coenzyme *A* or uroporphyrin-III. But they will find nothing about, say, hæmoglobin and its functions, and, as the author himself says, it is a far cry from the contents of this book to a dog or a cat or even a cabbage. One wonders whether the cry need have been quite so far as it is. No, the value of this book is not so much as an introductory guide to biochemistry for school children or for university students, but as a means of helping students to consolidate and summarize biochemical knowledge which they have gained from their lectures and text-books. Here it will fulfil a most useful purpose. The information, though so highly condensed, is clearly set out and is up to date. The book is well produced, and few misprints were noticed. The price is very moderate, and it was a good idea to make available a paper-backed edition at an even lower price.

D. C. HARRISON

Nuclear Electronics

Proceedings of the International Symposium on Nuclear Electronics organized by the French Society of Radioelectricians. (Sessions 1–5.) Pp. xii+452. (Vienna: International Atomic Energy Agency, 1959.) 84 schillings; 24*s*.; 4 dollars.

THIS volume contains the texts of fifty papers presented by delegates from the European countries and the United States at sessions 1–5 of the symposium on nuclear radiation detectors, associated pulse techniques and reactor control measurements and instrumentation. About a half of the papers are printed in English and the rest in French. A brief record of the discussion periods is given at the end of each of the five sections.

Session 1, on scintillation radiation detectors, includes a general review paper on the characteristics of phosphors and photo-multipliers developed during the past ten years and summarizes the important problems for future investigation. Separate papers deal with fast photo-multiplier tubes and with scintillation processes in phosphors, including variation of phosphor decay-time with specific ionization, and its application in differentiation of particle types. Session 2 is devoted to other types of radiation detectors used mainly in nuclear physics measurements, and includes short papers on ionization counters, scintillation in gases, a gas Cerenkov counter and semi-conductor radiation detectors. Three papers describe developments in gamma-ray spectrometry.

Session 3, on fast pulse techniques, includes a brief review of fast electronics in high-energy physics, and separate papers on trigger circuits, coincidence circuits, timing circuits and pulse generators for use in the nano-second time region. Session 4 on pulse techniques is devoted mainly to pulse-height analysers while Session 5 contains a short review on philosophy of reactor safety control in the United States, and several contributions on control systems and measurements in French reactors.

Much of the information has been published elsewhere in greater detail, but the collected papers will serve as a useful reference book on recent developments to designers and users of nuclear electronic equipment.

W. ABSON

Electromagnetic Radiation from Cylindrical Structures

By James R. Wait. Pp. ix+200. (London and New York: Pergamon Press, 1959.) 50*s*. net.

THE designer of aerials for aircraft and missiles must co-operate with the aerodynamicist and is therefore led to types of aerial which can be mounted on wings or fins without disturbing their aerodynamic properties. A satisfactory form of aerial is the slot, for which the behaviour in an ideal infinite conducting plane is well known. On an aircraft, however, the slot must be mounted on a relatively small conducting surface, which inevitably has an appreciable curvature. There is therefore a need to have information on the influence of curved surfaces on the radiation from slots and also from small dipoles mounted at right angles to the surface. The author of the present book has tackled this problem for those surfaces which admit the possibility of a formal electromagnetic solution. The surfaces include circular and elliptic cylinders, wedges and corner reflectors. In each case a detailed mathematical solution, usually in series form, is derived and comprehensive numerical results are given for the parameters likely to be of practical interest. These numerical results, which are given graphically, can be readily used by the practical designer even if he is not interested in the details of the theory.

The material is clearly presented and should be intelligible to the physics or electrical engineering graduate with a reasonable knowledge of electromagnetic theory. A useful appendix on the classical theory of radiation from current distributions serves as a revision of the fundamental results from which the main text is developed. An excellent feature is the frequent reference by the author to the similarity between radiation and scattering problems, and the reciprocity theorem is used to illustrate this. The volume is thus also of value to those interested in the theory of electromagnetic wave scattering. In particular, the short account of the work of Fock in this field provides an admirable introduction to the many original papers which use Fock's methods.

This book fills a gap in the existing literature and is strongly recommended to those with theoretical interests in aerials and electromagnetic scattering problems.

J. BROWN

USE OF LONG-LIVED NATURAL RADIOACTIVITY AS AN ATMOSPHERIC TRACER

By W. M. BURTON
Atomic Energy Research Establishment, Harwell
AND
N. G. STEWART
Dounreay Experimental Reactor Establishment

THE fission product activity in the atmosphere and in rain-water due to nuclear test explosions has been sampled in the United Kingdom and elsewhere for several years[1-3]. Studies of the distribution of some of the long-lived components of this activity, in particular, strontium-90 and cæsium-137, have revealed interesting seasonal variations and latitude distributions which have been interpreted as supporting the Dobson–Brewer model of atmospheric circulation deduced from measurements of ozone and water vapour[2]. Elements produced by cosmic rays have been proposed as possibly fruitful tracers for further studies of atmospheric movements[4].

A common feature of all such tracers, fission products, ozone and isotopes produced by cosmic rays is that their effective source lies in the stratosphere. They can consequently be used directly to study the mechanism of transport of air from stratosphere to troposphere, but not the complementary transport in the opposite direction. It seemed that a useful group of radioactive isotopes for this purpose would be the longer-lived, daughter products of radon—radium-D, -E and -F—which are naturally present in the atmosphere as a result of the leakage of radon from soils and rocks on the Earth's surface.

This article gives the results of an exploratory survey of the distribution of these isotopes in air and in rain-water, derives certain conclusions from these and points to the value of a more comprehensive programme.

Radon Decay Products

Radon is one of the elements formed by the radioactive decay of uranium which is present in greater or lesser degree in rocks and soils all over the world. Being a gas, radon can escape from the Earth's crust into the atmosphere, where it disintegrates radioactively to form a chain of solid daughter products, each of which is produced by the disintegration of the preceding one, the final element being lead, which is stable. The half-lives and radiation characteristics of the decay products are shown in Table 1, where for clarity minor branches of the decay series have been omitted.

Table 1. RADON AND ITS DECAY CHAIN

Chain member	Isotope	Half-life	Radiation
Radon	Radon-222	3·8 day	α
Radium-A	Polonium-218	3·1 min.	α
Radium-B	Lead-214	26·8 min.	$\beta\gamma$
Radium-C	Bismuth-214	19·7 min.	$\beta\gamma$
Radium-C′	Polonium-214	160 μsec.	α
Radium-D	Lead-210	19·4 yr.	$\beta\gamma$
Radium-E	Bismuth-210	5·0 day	β
Radium-F	Polonium-210	138·4 day	α
Radium-G	Lead-206	Stable	—

The daughter products are ultimately washed out of the atmosphere in rain after a mean period of residence in the troposphere of about 20 days (par. 2 of Discussion). The half-lives of the radium-A, -B, -C and -C′ are short compared with this mean residence time, and these isotopes are generally found to be in secular equilibrium with each other and with the parent radon[5]. Since radium-D takes some 80 years to reach equilibrium with radon, it is removed from the atmosphere by rain long before this state can be reached. Thus, typical values of the concentration of radon over land and sea are 200 d.p.m./kgm. (disintegrations per min. per kilogram of air) and 4 d.p.m./kgm., respectively[6], but the mean value of the radium-D concentration at ground-level reported by Blifford is only 0·03 d.p.m./kgm.[7]. For the same reason it is to be expected that the radium-E concentration will be less than that of radium-D, and radium-F less than radium-E. The low concentration of all these isotopes makes it necessary to pass large volumes of air through filters in order to obtain samples large enough for analysis, and complications can result from the collection of soot and other airborne dusts which may interfere with subsequent chemical separations.

Sampling Procedures

Air sampling programme. Ground-level air samples were collected at a height of 1 m. above the grass airfield at Harwell using cylindrical filters of esparto grass paper through which about 6,000 kgm. of air were passed at a mean linear speed of 140 cm./sec. during a normal 24-hr. period[1]. Above ground-level the samples were collected on filters attached to aircraft which were flown, primarily to collect fission products, at various fixed altitudes up to 48,000 ft. Some of these samples were obtained on disk filters fitted in a tube which carried an orifice plate for measuring airflow during flight. In general, the amount of air sampled in each such flight was too small for analysis; but by combining and analysing a batch of several filters from the same altitude it was possible to determine mean values of the specific activity at that altitude. On other occasions, a cylindrical filter was flown together with the disk, and the much larger amount of air thus sampled was determined from the ratio of the fission product activities of the two filters and the airflow through the disk. Typical linear sampling velocities were 460 cm./sec. at 18,000 ft. and 350 cm./sec. at 48,000 ft. The filters analysed were collected at various times between 1951 and 1957.

The efficiency of filtration is subject to uncertainty; but this is not considered to be serious. The radon daughter products are created as individual atoms in the decay process, and filtration efficiency is known to be high for such particles[8]. However, it has been demonstrated that the atoms can become attached to condensation nuclei in the atmosphere[9], and in this form filtration efficiency may be lower. Recent measurements made at Harwell[10] have shown that at sampling velocities in the region of 400 cm./sec. the sampling efficiency of esparto paper has a minimum value of 40 per cent for condensation nuclei of diameter 0·06 μ. The efficiency increases rapidly with diameter and has a value of about 70 per cent at 0·08μ. Mobility studies have shown that, when first formed, condensation nuclei have diameters in the region of 0·001μ, but they coagulate rapidly and reach 0·01μ in about 1 hr. and have increased to 0·08μ in about 30 hr. The atmospheric residence-time of daughter product atoms will be shown to be about 20 days, and during this period it is probable that the nuclei to which they are attached are larger than 0 08μ, and that the sampling efficiency is relatively high. A value of 100 per cent has been assumed in this article.

Rain-water sampling programme. Samples of rain-water were collected at Harwell in polythene bottles using two identical polythene funnels each with a 5-cm. rim and a collecting area of 2,000 cm.². Each funnel and storage bottle was cleaned and rinsed with distilled water before sampling began. To eliminate the possible effect of dry deposition on the funnel, the apparatus was only set up when a period of steady rain was beginning and it was taken in as soon as the rain stopped. The samples were acidified with nitric acid, carriers (lead and bismuth) added, and the volume measured before returning the samples to polythene bottles to await evaporation and chemical analysis. By independent analysis of the samples collected in the two units a check could be made on the reproducibility of the subsequent processing of two similar samples. Typical collections provided 2–6 litres of rain-water during a sampling period of a few days.

Chemical Separation Methods

The measurement of small quantities of radium-D, -E and -F in air and rain-water samples is complicated by the presence in the atmosphere of fission products from nuclear test explosions. During the course of the present experiments, the fission product concentration in air was very variable and generally exceeded the radium-D concentration by a factor of 100 at least. Trace-level experiments were carried out with solutions of radium-D, -E, -F and fission products and a complete separation procedure was worked out, based on solvent extraction of the dithizone complexes of lead and bismuth. Full details are given elsewhere[11]. The extracted isotopes were measured using standard low-background Geiger and scintillation counters.

The analytical method extracted at least 80 per cent of the radium-D, -E and -F from the samples and the limit of significant measurement was 2 d.p.m. The radiochemical purity of the separated isotopes was satisfactory, and in test extractions less than 0·01 per cent of the fission product activity initially present remained in the final radium-D fraction. In some cases, radium-D, -E and -F were measured on the same sample, but in most samples the analysis was limited to radium-D and radium-E or to radium-D and radium-F.

Results

Atmospheric concentration of radium-D. The concentration of radium-D in the airborne dust collected on air filters was estimated by two independent methods. In the first method, radium-F analyses were carried out on air filters which had been stored for several years after the dust samples had been collected. During this period the radium-F collected during sampling had almost completely decayed, while fresh radium-F had grown into equilibrium with the radium-D originally collected on the filter. Consequently, the radium-F content of the filters could be used to estimate the amount of radium-D collected by the filter at the time of sampling. In most cases, more than two years had elapsed between sampling and the chemical separation, so that the radium-F was at least 95 per cent of its final equilibrium concentration. In a few cases, the theoretical build-up was only 85 per cent, and a correction was added to the derived radium-D concentration. The results of these measurements are given in Table 2. Where more than one filter is specified in column 3, these were collected at different times during the stated periods but were combined for analysis. The standard deviation (*S.D.*) of each of the values in column 6, due to errors in air flow measurement, chemical analysis and counting, is estimated to be less than ± 15 per cent.

In the second method the samples were stored for about twenty days to allow the radium-E to come into equilibrium with the radium-D, and separate analysis of the two isotopes was carried out. The measured amounts generally agreed to within 20 per cent,

which is consistent with the estimated *S.D.* of ± 10 per cent on each individual determination. The results of these analyses are given in Table 3.

The averaged concentrations of radium-D determined by both methods are plotted against the altitude of sampling in Fig. 1 to give the vertical distribution of radium-D. The numbers in parentheses adjacent to each point refer to the number of separate samples used. It is clear that the two methods of measurement are in good agreement and that it is possible to draw a smooth curve through the experimental points. This agreement provides a measure of confidence in the sampling, separation and averaging procedures and suggests that the number of samples, although small, is adequate. There is, however, a systematic error inherent in the sampling procedure for radium-D arising from the fact that the filter paper collects the short-lived radon daughter products from the air, and these afterwards decay to form more radium-D on the paper after collection. This error is likely to be greatest at ground-level, where the concentration of radon is highest, but it can be shown to be small. Gale[5] has found that the mean concentration of radium-A, -B and -C in ground-level air at Harwell is 115 d.p.m./kgm. Collected on a filter paper, this would give rise to an apparent concentration of radium-D of $1 \cdot 2 \times 10^{-4}$ d.p.m./kgm., which is less than 2 per cent of the observed mean value of $7 \cdot 1 \times 10^{-3}$ d.p.m./kgm.

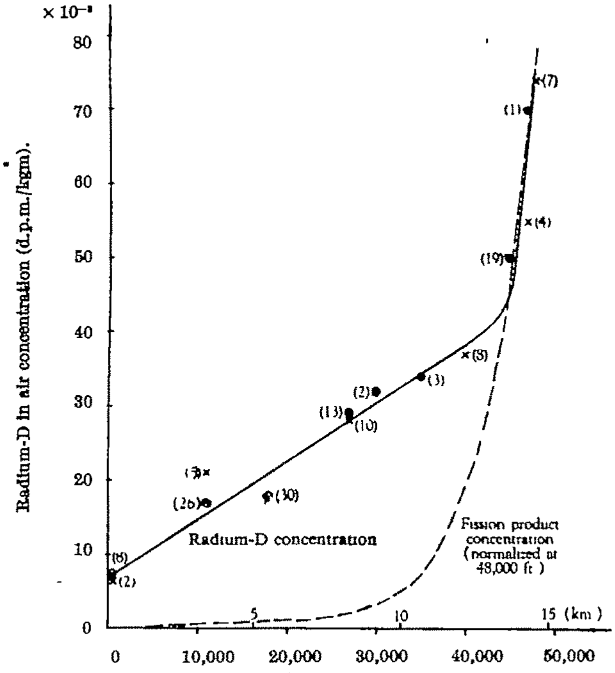

Fig. 1 Vertical concentration gradient of radium-D and fission products in the atmosphere above the United Kingdom. ○, radium-D from radium-D analysis; ×, radium-D from radium-F analysis. Numbers in brackets denote number of filters analysed

Atmospheric concentration of radium-F. Some analyses of radium-F were carried out on recently flown filters in which the measured radium-F concentration was practically the same as existed in the air during the sampling period. In a few cases the time-interval between sampling and analysis was long enough for the radium-F concentration to be affected, and in these cases a small correction was applied. The results of these measurements are shown in Table 4. The samples are grouped so as to average the radium-F concentration at three mean heights: ground-level, 27,000 ft. and 45,000 ft. The lack of data makes the form of the radium-F concentration curve uncertain, but it is clear that the concentration varies from a low value at ground-level to a high value in the lower stratosphere. The actual weighted mean values are $0 \cdot 9 \times 10^{-3}$ d.p.m./kgm. at ground-level and 30×10^{-3} d.p.m./kgm. at a weighted mean height of 45,000 ft. By comparing these values with those for radium-D in Fig. 1 it will be seen that the ratio of radium-F to radium-D is 0·13 at ground-level, increasing to 0·65 at 45,000 ft. This ratio in the lower stratosphere was also measured using a filter through which a large but unmeasured amount of air had been passed. The observed ratio of radium-F to radium-D in this case was 0·60, which is in good

agreement with the mean value of 0·65 determined above.

Concentration of radium-D and -F in rain-water. Each rain-water sample was analysed for both radium-D and -F and the results are given in Table 5. On two occasions duplicate chemical analyses were carried out on samples obtained from adjacent collectors In one case the results agreed to within ± 10 per cent and in the second case to ± 20 per cent, but the radium-F to radium-D ratios in each pair were in excellent agreement. The specific radium-D activity is seen to vary substantially from day to day, but the mean value of 5 d.p.m./litre over the period September–December 1956 is in good agreement with Blifford's value of 5·3 d.p.m./litre observed in Washington, D.C.[7]. The mean radium-F : radium-D ratio of 0·10 in the same period agrees with the ratio of 0·13 found in air at ground-level. This is to be expected since rain collects its dust from the lowest layers of the atmosphere.

Discussion

Radium-D in the stratosphere. The first striking feature of the results is that the concentration of radium-D in the atmosphere above the United Kingdom increases with height above ground and that the gradient increases sharply in the vicinity of the tropopause (Fig. 1). A similar discontinuity has been observed in the gradient of fission product dust from the thermonuclear explosions in Eniwetok in 1954 in which the dust clouds were injected high into the stratosphere[1]. A feature of the distribution of these fission products was that the stratospheric gradient had, within experimental error, the same value some 6 months, 12 months and 18 months after the explosions and this appeared to be a characteristic of the descending cloud. A normalized version of the fission product distribution curve is shown in Fig. 1. It will be noted that the stratospheric gradient of radium-D is very similar to the characteristic fission product gradient. This suggests that in the middle latitudes, where sampling was carried out, radium-D is descending from the stratosphere in a manner similar to the fission products. One possible source of this radium-D is in meteoric and volcanic dusts, which are known to diffuse into the troposphere from high altitudes. However, an approximate calculation indicates that the maximum contribution from these sources cannot account for more than about one millionth of the observed radium-D. We conclude that the radium-D has its origin in the tropopause and has entered the stratosphere at some earlier stage of its history.

Important features of the exchange processes between the stratosphere and the troposphere have been revealed by the work of Dobson and Brewer on the ozone and water vapour content of the atmosphere and a model of the general circulation based on their deductions is shown in Fig. 2. Dobson[12] explained the observed seasonal variations in total ozone by suggesting that the cold pool of air which forms above the winter pole when it is in shadow ultimately sinks and carries ozone-rich air to the lower levels of the stratosphere. In order to explain the form of the water-vapour curve in the stratosphere, Brewer[13] has suggested the circulation system shown in the model in which tropospheric air enters the stratosphere near the equator, travels to temperate and high latitudes and then sinks into the troposphere again. Fission product studies have supported this model. Thus, it has been shown that the rate at which fission products re-enter the troposphere from the stratosphere varies in the same seasonal manner as the total ozone[2]. Again, the concentration of fission products in air and in rain-water has a pronounced minimum in equatorial regions and a peak in the middle latitudes of the northern hemisphere, suggesting that this is where

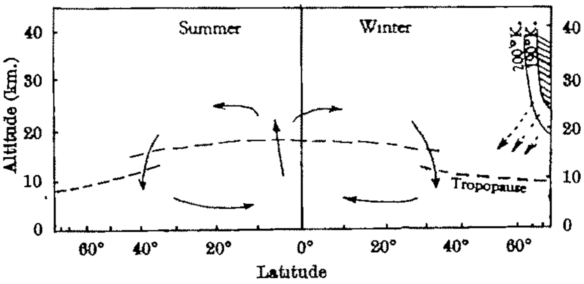

Fig. 2. Atmospheric circulation model (Dobson and Brewer)

the descending fission products re-enter the troposphere.

If this model is accepted, then the source of the radium-D in the stratosphere is the ascending air at the equator, which carries with it not only radium-D but also radon and its daughter products from which more radium-D will be formed.

Radium-D in the troposphere. The radium-D in the troposphere is a combination of two components, one of which is the radium-D descending from the stratosphere while the other is radium-D which was created and has remained in the troposphere. If we assume that the stratospheric component behaves similarly to fission products, then Fig. 1 shows that the tropospheric component predominates and that this component increases with height. At first sight this is surprising since the parent radon is known to originate at ground-level. The explanation is that the radium-D in the troposphere above the United Kingdom is characteristic of Atlantic air and is largely independent of any radium-D formed locally. In its passage across the Atlantic, the parent radon can diffuse above the rain-producing layer in the troposphere into a region where the radium-D formed is not subjected to washout. Radium-D at lower levels is subject to washout and the overall effect is to produce a positive concentration gradient in the troposphere.

It is possible from the results obtained to derive two independent estimates of the mean life of a radium-D atom in the troposphere. First, we can compare the radium-D content of a vertical column of air with the mean rate at which radium-D is deposited by rain. From Fig. 1 the radium-D content of 1 $m.^2$ column reaching from ground-level to the tropopause at 40,000 ft. is 167 d.p.m. The mean radium-D content of rainwater is 5 d.p.m./litre, so that an average rainfall of 2 mm./day (characteristic of the middle latitudes of the northern hemisphere[14]) deposits 10 d.p.m./$m.^2$/day. This points to a mean life of 17 days, a figure which would be proportionately higher if the efficiency of air sampling were less than the 100 per cent assumed.

A second rough estimate can be obtained from the ratio of radium-F to -D in the activity deposited in rain-water. If we make the reasonable assumption that the radium-D, -E and -F particles are washed out with equal efficiency by rain, then it can be shown that the radium-F to -D activity ratio is given by the expression:

$$\frac{\text{radium-F}}{\text{radium-D}} = \frac{T^2}{(Te + T)\,(Tf + T)} \qquad (1)$$

where Te = radioactive mean life of radium-E = 7·2 days; Tf = radioactive mean life of radium-F = 200 days; T = mean residence time of an individual atom in the atmosphere.

The mean ratio in the bulked rain-water collected was 0·10 and substitution in equation (1) gives T = 29 days. This figure, however, represents the mean residence time of the combined tropospheric and stratospheric components, and since the latter has been airborne for a longer time, it is high for the tropospheric component alone. Thus, if we assume that rain-water removes the activity from a mean height of 6,000 ft., then using Fig. 1 and the observed value of the radium-F/radium-D ratio in the stratospheric component, it can be calculated that the radium-F/radium-D ratio in the tropospheric component of rain-water is 0·075. This gives a value of T = 22 days for the mean residence time of those atoms the whole airborne life of which is spent in the troposphere.

Since each radon atom ultimately produces a radium-D atom, a final check on the consistency of the results can be made by comparing the amount of radon exhaled from the ground into the atmosphere with the amount of radium-D deposited by rain. Israel[9] has summarized the radon measurements made in many parts of the world and has shown that the mean rate of exhalation of radon from the Earth's surface, measured directly, is 7·7 × 10^4 d.p.m./$m.^2$/day, while the value derived from the measured concentration of radon in the atmosphere is 7 2 × 10^4 d.p.m./$m.^2$/day. Since land occupies 39·3 per cent of the surface of the northern hemisphere, we may take a mean radon exhalation-rate of 2·8 × 10^4 d.p.m./$m.^2$/day. This is equivalent to a production-rate of 15 d.p.m./$m.^2$/day of radium-D, which is in reasonable agreement with the measured deposition-rate of 10 d.p.m./$m.^2$/day computed above for a mean rainfall of 2 mm./day.

Circulation time of air entering the stratosphere from the troposphere. The ascending equatorial air shown in the model in Fig. 2 will carry with it radon, radium-D and -F together with the other less-important radon daughter products. Since the mean rainfall-rate is higher at low latitudes than in the middle latitudes it is possible that the radium-F will be even more deficient with respect to radium-D than it was in the troposphere above the United Kingdom. When the air enters the stratosphere, it becomes insulated from washout processes, and the radium-F can begin to build up towards its 'equilibrium' value with respect to radium-D, and consequently the radium-F : radium-D ratio in any mass of stratospheric air can be used as a measure of the length of time the air has been in the stratosphere. In particular, by comparing the ratio in equatorial air with that in air in the lower stratosphere above the United Kingdom the period of the circulation process depicted in Fig. 2 can be determined.

One unknown is the composition of equatorial air, but this does not have a major influence on the estimate. If the ascending air contained radium-D alone, then the observed radium-F : radium-D ratio of 0·65 at 45,000 ft. above the United Kingdom would correspond to a circulation time of 212 days. If pure radon was the original constituent, the time would be a little longer. These are upper-limit estimates and are highly unlikely in practice. Another assumption to make is that the ascending air has the same isotopic composition as the air near ground-level in the United Kingdom. This leads to an estimated circulation time of 177 days, which would be low if the radium-F : radium-D ratio in the equatorial troposphere were less than that in the middle latitudes. The true figure should be between these extremes and the best estimate is therefore of the order of six months.

Suggestions for Further Work

The radium-D, -E, -F measurements have been interpreted in terms of an atmospheric circulation model which appears to fit the facts. Other interpretations are possible, however, and future studies might be directed towards discriminating between the possibilities. L. Machta[15] has pointed out that the steep gradient in the stratosphere could be explained by an extension of the argument in par. 2 of the Discussion, which accounted for the positive gradient in the troposphere. In this 'diffusion' model, the source of the radium-D in the stratosphere is the radon and its daughters which diffuse through the tropopause into the stratosphere and afterwards decay into radium-D. The difference in gradient is due to differences in the diffusion constants appropriate to troposphere and stratosphere. This explanation would appear to require a greater value of the stratospheric diffusion constant than has hitherto been considered reasonable, but the matter might be settled by measuring the radon content of the lower stratosphere to establish if there was enough there to support this hypothesis. It would also be instructive to investigate the concentration of radium-D in the stratosphere in more detail than was possible here, to determine if it was subject to the seasonal variations observed with ozone and with fission products.

Conclusion

The development of a radiochemical separation procedure has enabled a preliminary study to be made of the distribution of radium-D and radium-F in the atmosphere. Systematic results have been obtained which suggest that radium-D is a valuable natural tracer for the further study of atmospheric processes.

The work described in this article was carried out in the Health Physics Division at the Atomic Energy Research Establishment, Harwell; we thank the Director of the Establishment for permission to publish this communication, and also the Royal Air Force for the collection of the airborne dust samples.

FUEL CELLS: WILL THEY SOON BECOME A MAJOR SOURCE OF ELECTRICAL ENERGY?*

By F. T. BACON

Marshalls Flying School, Cambridge

THE efficiency of all heat engines, that is to say, engines in which heat is converted into mechanical work, is governed by Carnot's cycle; this means that the efficiency is limited in practice by the difference in the temperature at which the heat is taken in by the working fluid and the temperature at which it is rejected. It is the possibility of avoiding the Carnot limitation which constitutes the main, but not the only, reason for interest in fuel cells.

Present-day Fuel Cells

A fuel cell can be defined as an electrochemical cell in which the free energy of combustion of a fuel is converted directly into electrical energy. Gaseous fuels are very convenient for use in electrochemical cells, and either oxygen or air is used as the oxidant. There are various ways of classifying the different types of fuel cell that are now being tried, but it is convenient to divide them up into those working at atmospheric temperature up to, say, 100° C.; those working at a medium temperature, around 200° C.; and those working at a high temperature, say 550° C., and upwards, with electrolytes of fused salts.

Those which work at a low temperature must, as a general rule, have electrodes with a very large internal surface if reasonably large current densities are to be attained; this is usually achieved by using highly porous materials, either porous carbon or porous metals. Porous carbon is peculiarily suitable for the purpose, and surfaces as large as 200 sq. m. per gm. are commonly used. The activity of the electrodes is often further increased by impregnation with catalytically active materials. The electrolyte in low-temperature cells usually consists of a strong aqueous solution of an alkali such as potassium hydroxide, which has a good conductivity. Work is proceeding in the United States on a rather different type of cell which has an ion-exchange membrane as electrolyte; the internal resistance of this type of cell is liable to be rather high, and the figures for performance which have been published so far are rather low; but, on the other hand, if the electrolyte is of the acidic type, ordinary untreated air containing carbon dioxide can be employed without any danger of carbonating the electrolyte. It can be safely said that the best results in low-temperature cells have so far been obtained with pure hydrogen and oxygen, as might be expected.

Cells which work at a high temperature use a mixture of fused salts, usually carbonates, as electro-

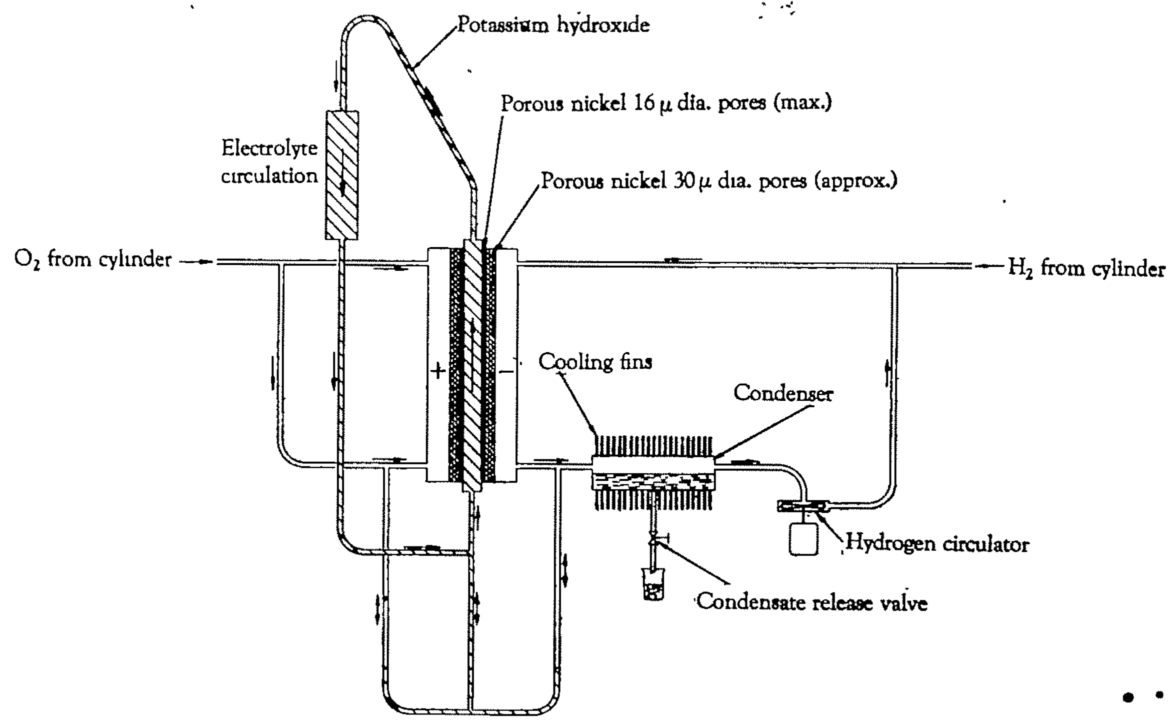

Fig. 1. Hydrogen – oxygen cell

lyte, and this is often contained in a porous diaphragm of sintered magnesium oxide. The electrodes may be of some metal or metal oxide, which must, of course, be kept in close contact with the porous diaphragm. This kind of cell may operate from about 550° up to, say, 800° C., but difficulties with corrosion become greater as the temperature is raised; the pressure is atmospheric. The great advantage of high-temperature cells is that they will consume impure industrial gases, or vaporized hydrocarbons such as kerosene, and air; this is, of course, a fundamental advantage in a genuine fuel cell—it uses cheap and readily available fuels.

The reacting gases in medium-temperature cells are usually hydrogen and oxygen; the theoretical efficiency at atmospheric temperature and pressure is about 83 per cent (based on the total heat of the reaction), and practical efficiencies of about 55 per cent have been obtained at 200° C. and a pressure of 400 lb./sq. in. Work on the high-pressure hydrogen/oxygen cell is now being financed by the National Research Development Corporation.

The electrodes of porous sintered nickel are about one-sixteenth of an inch thick, or less, and the electrolyte is strong potassium hydroxide solution. Fig. 1 shows the arrangement adopted in 1949 and which is still virtually unchanged.

The electrodes are made with a pore size of about 30 microns on the gas side and with a thin layer of much smaller pores on the liquid side; a small pressure difference is set up in the apparatus across each electrode, so that the liquid is expelled from the large pores on the gas side, but the gas cannot bubble through the small pores on the liquid side owing to the surface tension of the liquid. The interior of the 30-micron pores presents a large surface for absorption of gas.

Thus, in a porous metal electrode of this kind, the current density is kept low by the large internal surface of the large pores, and the gas side of the electrode is kept substantially dry, an essential condition for good performance.

The oxygen electrodes are first impregnated with mixed nitrates of nickel and lithium; they are then dried and roasted in air at about 700° C.; in this way they are coated with a conducting oxide layer which is very resistant to corrosion in the cell. Oxygen electrodes treated in this way have lasted for 1,500 hr. in the cell at 200° C. with a drop in output of less than 4 per cent.

The present 10-in. diameter electrodes are not strong enough to be self-supporting against the pressure difference, so they are sintered directly on to solid plates of nickel or nickel-plated steel, which have a large number of holes drilled or punched through them so that gas can readily get through from the other side. Fig. 2 shows the best cell characteristic so far obtained with this size of electrode, and

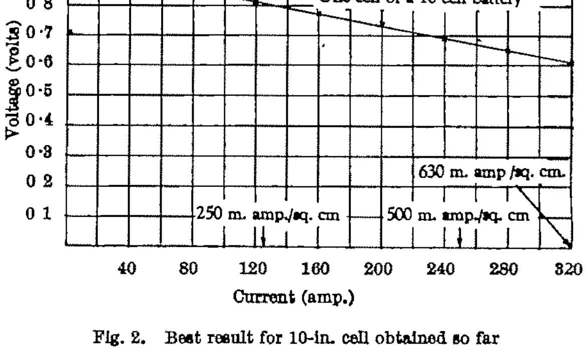

Fig. 2. Best result for 10-in. cell obtained so far

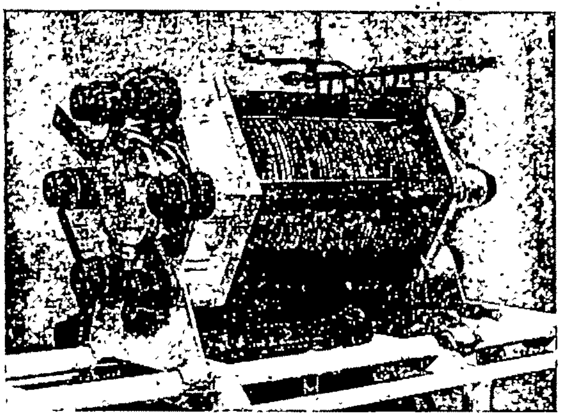

Fig. 3

it will be seen that currents as large as 320 amp. have been achieved.

Longitudinal ports are provided for feeding the two gases and the electrolyte to each individual cell. If bipolar electrodes can be made, a great saving in space and weight will be obtained.

Fig. 3 shows the largest battery built up so far; it has 40 cells, giving an open-circuit voltage of about 40; this gave a performance of 100 amp. at 32 V., or 3·2 kW., and 240 amp. at 24 V., 5¾ kW.

Advantages and Disadvantages of Fuel Cells

It is quite plain that if a fuel cell can be produced which will accept ordinary fuels such as coal, oil or gas, and atmospheric air, a vast field of application is open to it, on both a large and a small scale. Unfortunately, coal must be ruled out, as there is no sign of any cell which can make direct use of it; so we are left with oil in its various forms which can easily be vaporized if necessary, and gas which may be made from coal. Both oil and gas could be considered for large- and medium-scale generation, especially where natural gas is available; and the piping of natural gas over really long distances is now being considered. For large-scale generation, oxygen would probably be too expensive, so air would have to be used. A pressure cell would seem out of the question, owing to the cost of compression, so it seems fairly certain that a high-temperature cell with a fused salt as electrolyte is the answer in this case. Direct current is, of course, generated, so large-scale inversion would have to be considered, unless the device is used for, say, a locomotive, where direct current is desirable.

But the cell on which there is a great deal of controversy at present is the hydrogen/oxygen cell. If it can be brought to the stage of practical application, is it going to be any use in practice? The objections raised are mainly that pure hydrogen is an expensive fuel and is difficult to store; and the oxygen must be carried, too, and this is more expensive than air, which is free. Further, there is no highly developed distribution system, equivalent to that for petrol or diesel fuel. These are important arguments and must be faced.

It is usually agreed that the hydrogen/oxygen cell is essentially a storage device, rather than a genuine fuel cell using a primary fuel, and furthermore, it will be used mainly for road and rail traction. This means that the two gases will be produced by the electrolysis of water, probably in a separate apparatus. Thus the existing electricity grid would provide the distribution system for the fuel, electricity; and the gases would be generated locally. The battery would, of course, produce direct current, which is convenient for driving a vehicle. Considerable developments have taken place in recent years in the field of high-pressure electrolysers, and this should have the effect of reducing the cost of production of compressed hydrogen and oxygen in course of time.

Then there is the further interesting possibility that this particular cell could be made reversible, although it is not fully reversible yet; this should be a great advantage on any vehicle which has to start and stop repeatedly.

It must be admitted that gases are intrinsically difficult to store because they require heavy and bulky gas cylinders; it is tempting to consider storing them as liquids at a low temperature, and in this respect oxygen does not present much difficulty. But hydrogen is much more difficult, and although liquid hydrogen is made in quantities as great as 7 tons per day in the United States for use in rockets, it is still rather expensive. So, in the meantime, we are driven back to gas cylinders.

But the advantages of silence, freedom from fumes and vibration, and very few moving parts, should not be overlooked, and in certain special applications could be important. Further, it is well known that the torque characteristics of a direct-current motor are far better than those of an internal combustion engine which has to rely on a clutch and gearbox for starting. It seems that the hydrogen/oxygen cell is essentially a high-performance device, and therefore inherently suitable for traction.

One further point is that, as more nuclear power stations are built, it will become even more important to look for some method of storing electricity; it is well known that the main proportion of the cost of electricity produced in this way is due to the capital cost of the plant rather than the amount of nuclear fuel used, so that little is saved by shutting them down during time of light load. The present suggestion is that the electrolysers should be kept running at all times, except during the peak-load period, and that the gas produced should be used for driving some of our road and rail vehicles as and when required.

Practical Demonstrations

It is scarcely necessary to discuss applications for fuel cells, as these are fairly obvious if all the technical difficulties can be overcome, and the cost is not too great. The applications for a cell consuming either natural gas or liquid hydrocarbons and air would be enormous, both for static and mobile plant, and the great oil companies have started research work on the problem.

Practical demonstrations have already been given of fuel cells in use. A battery of hydrogen/oxygen cells developing 1 kW. was demonstrated in the United States about two years ago, as a power unit for a mobile radar set used by the U.S. army; it is known as the *Silent Sentry*, and in this case silence was its great virtue.

A demonstration took place at Cambridge in August 1959 of the high-pressure hydrogen/oxygen cell, in which a 40-cell battery was shown operating a small circular saw, providing power for arc-welding, and operating a fork-lift truck. The maximum power was about 6 kW.

A demonstration was given in the United States in October 1959 of a farm tractor driven by a battery of fuel cells supplied with propane and other gases (probably hydrogen) and oxygen. It has 1,008 cells in series and works at quite a low temperature; no details were given of the construction of the cells, but the electrodes must be very active catalytically to be able to make use of propane at a low temperature. 15 kW. is developed. This is the first time that a vehicle has been demonstrated propelled by a fuel cell-battery mounted on the vehicle. This is a great achievement, though the makers are careful to add that it is still a research vehicle.

Conclusion

Why is it that there is so much interest in the United States, and more recently in Germany, in fuel cells, and there is still so little in Britain, though this was where most of the original work was done? Part of the great effort in the United States is no doubt sponsored by the Federal Government, as there are certain military applications where fuel cells would be very valuable; and there is the vast satellite and space vehicle programme, where batteries are used extensively for providing auxiliary power. This is not the whole story, however, as some large companies are putting their own money too into research on fuel cells. It seems that the explanation is that the idea has 'caught on' in the United States, whereas in Britain it has not, as yet; and in any event, American firms are prepared to set aside enormous sums of money for research and development, even on comparatively speculative devices such as fuel cells.

It is, of course, known that the world reserves of coal, oil and natural gas are very great, but we are using them up faster now than ever before; the fuel reserves in Great Britain are not great, in comparison, and practically all oil has to be imported. Surely attention should be given to any device which might show an economy in the use of fuel. Part of the purpose of the vast atomic energy scheme in Britain was to help to conserve dwindling coal supplies; if a small part of the effort devoted to atomic energy could be given to a study of fuel cells in all their possible forms, an answer would probably be obtained within a very few years.

PRELIMINARY FLIGHT TESTS OF AN ATOMIC CLOCK IN PREPARATION OF LONG-RANGE CLOCK SYNCHRONIZATION EXPERIMENTS

By FRIEDRICH H. REDER and GERNOT M. R. WINKLER
U.S. Army Signal Research and Development Laboratory, Fort Monmouth, New Jersey

THE performance of atomic and molecular frequency standards has been the subject of intense studies for several years[1-3]. In particular, tests have been made with a commercial cæsium beam frequency standard[4] ('Atomichron') under various environmental conditions. The 'Atomichron' employs a crystal oscillator which is continuously servo-controlled with respect to a microwave resonance of cæsium atoms. Usually the 'Atomichron' is employed to calibrate and check, at regular intervals, the rate of precision crystal clocks. It can, however, also be operated to drive a clock directly (within the life-time of the cæsium beam tube, which may be better than 6,000 hr.). Irregularities in time as small as one µsec. after 100 hr. have been achieved[5] during laboratory operation of the clocks in a controlled-temperature environment and with a stabilized power source. As an extension of these tests, flight experiments have been carried out with an operating atomic clock of the type mentioned above in preparation for a large-scale clock-synchronization project[6] aiming at an error of less than 1 µsec. between clocks separated by more than 1,000 miles. It is the purpose of this article to describe briefly the preliminary flight experiment and its results.

One atomic clock was operated from a voltage regulator in an air-conditioned laboratory room. The other clock was mounted in a *DC*-3 aircraft. All measurements were done in the laboratory by utilizing a microwave link between laboratory and airport, which are separated by a distance of 10 km. Both one-sec. pulses and the 100-kc /s. output signal were used to measure rate and time difference between the two clocks (Fig. 1). To ensure the least effect of Coriolis forces upon the atoms in the

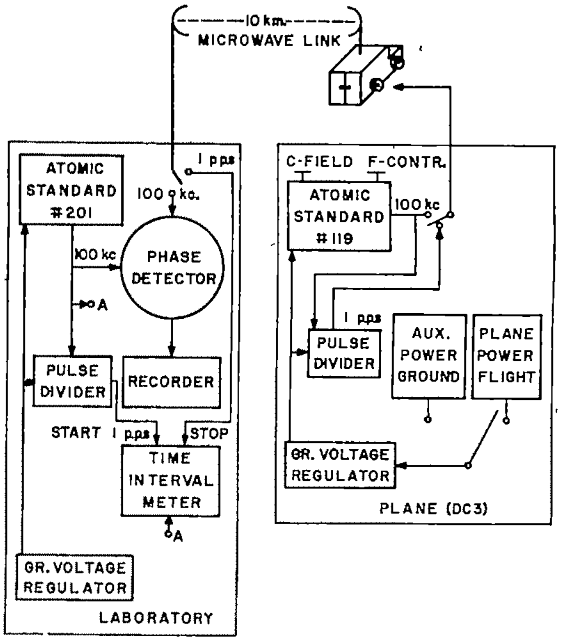

Fig. 1. Block diagram of measurement equipment for the flight test

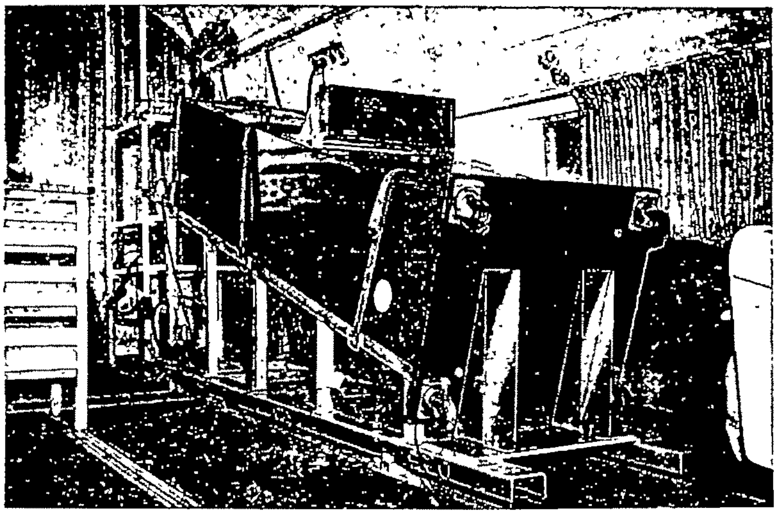

Fig 2. Position of atomic frequency standard in the aeroplane. Off-standing chassis contains the crystal oscillator on shock mounts

beam tube during flight, the plane clock was operated in an almost horizontal position (Fig. 2). While the aeroplane was on the ground, power for the equipment was furnished by a petrol generator mounted in the tail of the plane. Shortly before take-off, power was switched to the main board supply, with the line voltage input to the atomic clock being held constant by a buffer battery and a voltage regulator.

The aeroplane was unpressurized and without temperature control. However, the temperature was kept manually between 15° and 22° C. The flight altitude was about 330 m. above sea-level due to a very low ceiling.

One ½-hr. flight was made on November 16, 1959, and a 1-hr. flight on November 17. The pilots were instructed to turn not faster than about one complete turn per minute to avoid Coriolis effects. Despite considerable vibrations in the plane and rather unfavourable weather conditions on the second day, performance of the transported clock was quite astonishing (Figs. 3 and 4).

The uncertainty of time determination (after correction for the small rate of the clock) was less than 60 nanosec. after the shorter and smoother flight, and less than 150 nanosec. after the longer and rougher flight, which was plagued by a very short power failure caused by a faulty switching operation before take-off. It can be seen from Fig. 4 that this power failure resulted in a short-time perturbation of the relative rate of the two clocks. The results lead us to believe that synchronization of remote clocks by means of a shuttle plane is entirely feasible, and that, even with existing equipment, such synchronization will be about a thousand times more accurate than that at present possible through use of radio time signals.

Further extensive tests on synchronization of widely separated atomic clocks are in progress and will be reported soon.

OBITUARIES

Dr. Roy Chapman Andrews

DR. ROY CHAPMAN ANDREWS, famous for his Gobi Desert discoveries in the early 1920's, died in New York early in March. He was seventy-six. He was born at Beloit, Wisconsin, on January 26, 1884, and was educated at the comparatively small College there, graduating A.B. in 1906. He then proceeded to Columbia, where he took his A.M. degree in 1913. He also had some experience in the Museum of Comparative Zoology at Harvard. His later education was interrupted by his absences on expeditions, those forays and excursions, often with important scientific and geographical results, that were to be the main interest of his life and the foundations of his undoubted eminence.

His association with the American Museum of Natural History began in 1908 when he joined an expedition to Alaska; he did exploration work on the St. Lawrence in 1909, shortly afterwards becoming naturalist in the U.S.S. *Albatross*, which visited the Dutch East Indies and Borneo in 1909–10. During 1911 and 1912 he was in Korea and in 1913 he was back in Alaska. These were, however, but preludes to his main task, which came when, in 1916, he was appointed leader of the American Museum expeditions to Central Asia. From 1917 until 1931 he was intermittently in Mongolia and in China in pursuit of vertebrate fossils and the remains of man.

His chief, the distinguished director of the Museum, Prof. Henry Fairfield Osborn, held the theory that the likely area of the dispersal of mammals and of man was to be found in the Orient, and the expedition's results, if not exactly convincing for this theory, were encouraging in the considerable materials that they produced. Dinosaurs and dinosaurs' eggs earned the expedition fame, though the dinosaurs were not so important as many that had already been found, and dinosaurs' eggs had been discovered earlier in England and in France. Andrews also found small Cretaceous mammals and giant Tertiary mammals and mastodons, but not a scrap of the fossil man he was working for, though *Sinanthropus* was later to turn up not so very far from the house where he kept palæontological court in Pekin.

Judged by any standards, Andrews's Asiatic expeditions were a success, and resulted in considerable additions to many museums other than his own, for the American Museum was generous, and excellent representatives of the dinosaurs from the expeditions are in the British Museum (Natural History).

Scientific and other honours rightly came to him. He was made Sc.D. of both his native Beloit and of Brown University, Rhode Island. He also received many medals, mainly for the geographical aspect of his work, from the National Geographic Society and the Explorers' Club in his own country, and from the national geographical societies of Sweden and Hungary.

During 1931–35 Andrews was vice-director in charge of exploration and research at the American Museum of Natural History, and from 1935 until 1942 he was director. He retired in 1942 with the title of honorary director.

He was the author of ten books and many scientific papers. Most of these were written in his beautiful homes in Connecticut or in California, where successively he lived after his retirement. But they were far from being his only interests. The Boy Scout movement and many sports, mostly connected with horses, engaged his attention, and he was always a hospitable man.

His name will be remembered in the annals of vertebrate palæontology and in the history of the distinguished Museum he served so well for so long.

W. E. SWINTON

Mr. C. A. Shain

CHARLES ALEXANDER SHAIN, an outstanding member of the radio astronomy group at the Commonwealth Scientific and Industrial Research Organization (Australia) Radiophysics Laboratory in Sydney, died on February 11 at the early age of thirty-eight. His contribution to radio astronomy lay in the frequency-range around 20 Mc./s. where he pioneered the study of the two features peculiar to this range of radio astronomy: absorption in ionized interstellar hydrogen (H II regions), and absorption and refraction in the ionosphere. Observations in this frequency-range are particularly difficult owing to interference from radio stations and the complicating effects of the ionosphere; but they give unique information of great importance to radio astronomy. Shain's work is basic in this field.

Shain studied physics in the University of Melbourne and graduated in 1942. He immediately entered the second Australian Imperial Force, but was discharged on medical grounds late in 1943. He then joined the staff of the Radiophysics Laboratory, where he stayed until his death. During the remaining stages of the War, he worked on radar counter-measures, and from 1945 on various aspects of decametre-wave radio astronomy.

His work in radio astronomy began with a study of Moon echoes at a frequency of 20 Mc./s. This work, which was an immediate follow-up of the pioneering American and Hungarian experiments, led to the recognition of the dual causes of the fading of Moon echoes: libration of the Moon and propagation effects in the ionosphere. Using parts of the same equipment, he then began the observations of the distribution over the sky of relatively low-frequency (20-Mc./s.) cosmic radio waves which he continued until his death. He first used broadside arrays, the largest of which consisted of 30 half-wave dipoles and had a beam-width of 17°, and then a 'Mills cross' with arms 3,500 ft. long and a resolution of 1·4°.

In the first phase of these investigations he was able to show conclusively that the brightness distribution over the Milky Way at this frequency was markedly influenced by absorption in H II regions; but he had insufficient angular resolution to delineate even the largest of these regions, and his 'Mills cross' was designed to overcome this limitation. At the time of his death he had nearly completed a 19-Mc./s. map of the greater part of the Milky Way, which shows numerous examples of the obscuring regions which he sought. His colleagues plan to complete and publish this unique and important work as soon as practicable.

In this frequency-range, the absorption of cosmic radio-waves in passing through the ionosphere is often appreciable and the interpretation of cosmic observations requires a knowledge of absorption in the various ionospheric layers. Shain's pioneering work on such absorption, particularly interesting at the time of solar flares, sufficed for his own purposes and has since given rise to a vigorous branch of ionospheric research which follows the inverse approach and uses observations of the absorption of cosmic radio waves to obtain information about phenomena in the ionosphere.

A by-product of the cosmic radio wave studies concerns radio emission from Jupiter. Following the discovery in the United States in 1956 of emission from this planet in the 20-Mc./s. range, Shain examined his old records. He found a large number of extended bursts of emission, which had previously been attributed to terrestrial interference, but which could now be identified with reasonable certainty as due to emission from Jupiter. Examination of the times of occurrence of these bursts showed a remarkable correlation with the rotation period of Jupiter, indicating that the emission originated in a very few active areas on the planet which remained in fixed positions for long periods.

Alex. Shain was a wonderful colleague in the laboratory—imaginative, well balanced, exceedingly unselfish, and a real friend to all. In his home community he was a leader in Church affairs. In murra where he lived he was, among other things, the Anglican Church in the Sydney suburb of Turra-Sunday school superintendent, lay reader and the leader of a Bible Study Group. He was a man who exemplified the principles of Christianity in all his dealings with men.

J. L. PAWSEY

Mr. K. J. F. Park

THE death of Kenneth John Frederick Park in a drowning accident on March 2 at the age of thirty-two has robbed the Nature Conservancy of a most valued officer, science of a first-rate ecologist and the world of a man of rare quality.

Park was educated at the Royal Grammar School, Newcastle upon Tyne, and at King's College, Newcastle. Between school and college he served three years in the Royal Air Force, and this took him to the Middle East and gave width of experience to an alert mind. He left the University with a first-class degree in botany and a good knowledge of the arctic-alpine vegetation of northern England, the Scottish Highlands and the Hebrides. His interest in field botany led him to postgraduate work on the ecology of Upper Teesdale, particularly the sugar-limestone outcrops. This work was interrupted in 1954 by his appointment as officer-in-charge of the Nature Conservancy's Moor House Field Station more than 1,800 ft. above sea-level in the northern Pennines.

His basic scientific interest was the conservation of upland Britain, using the word conservation in a wide and humanitarian sense. His own research was focused on the potential productivity of the grasslands on mineral soils. He aimed to get quantitative data on long-term trends in fertility-levels, as determined by grazing, leaching, soil weathering and other factors causing gain or loss of nutrients. During the past year or two he had been attacking these problems directly, for example by observations on rates of leaching, but before this he had put in much intensive work on recording the existing state of the various grassland types on the Nature Reserve. He did this by setting up a series of sheep exclosures and using various methods of mapping, point-quadrat recording, and detailed photography of vegetation. The methods were not of course original, but the standard of accuracy and the finish of the work are altogether outstanding and are witnessed in the volumes of the Nature Reserve Record Book. The plots have been laid out and recorded as the firm starting-point for observations visualized as going on over a century or more.

Over and above his own research line, he built up an impressive collection of information about the Reserve and the surrounding countryside, and himself contributed many superb photographs.

When he went to the Field Station he had nothing to work on but rather sketchy possibilities; but in his six years of imaginative and efficient management, he created a live centre of scientific work in remote and difficult conditions, where visiting workers could come and use their time productively. His achievement was due not only to his very hard work and exceptionally high standards but even more to his personal qualities, which enlisted the co-operation of anyone who came into contact with him, and the devoted loyalty of all his colleagues, both senior and junior.

Dr. Paul Haas

PAUL HAAS, who died on April 6 at Cheam, was born in 1877, the son of distinguished parents. His father was professor of Sanscrit at University College, London, and his mother was a gifted pianist who, before her marriage, had a European reputation as a soloist. Even in her old age, Madam Haas played the music of Bach in a manner few could equal, and her son inherited musical appreciation.

Paul Haas was educated at University College School when it was in Gower Street, then at University College, and he studied also both at Freiburg and Geneva. As an investigator, he was very deliberate and conscientious. With the late Prof. T. G. Hill, he collaborated in the investigation of the biochemistry of seaweeds and the chromogens of *Mercurialis perennis*, and they produced, in 1913, "An Introduction to the Chemistry of Plant Products", which was afterwards extended into a two-volume work.

It was in teaching, however, that Haas found his chief interests, and his lectures and demonstrations were always carefully prepared. He lectured on organic chemistry both at St. Mary's and St. Thomas's Hospital Medical Schools, and also at the Royal Botanic Gardens, Kew, until he became reader in plant chemistry at University College, of which he was a Fellow.

Paul Haas had a retiring kindly personality with a quiet sense of humour. He looked after his mother devotedly, at their home in Westbourne Park, until her death, and his colleagues had regarded him as a confirmed bachelor. But romance came to him when inspecting schools for the University of London, and at the age of sixty-one he married Beryl Grace Wood who, with a son of the marriage, survives him.

E. J. SALISBURY

Prof. J. A. Hanley

The death of Prof. J. A. Hanley on April 10 occurred after several years of physical handicap, gallantly borne with the help of his devoted wife, following a breakdown in health he suffered in the post-war years. He has been living during this period of retirement from his academic career in Applethwaite, near Keswick. His last appointment was that of professor of agriculture and rural economy in King's College, University of Durham, Newcastle upon Tyne, where he directed the work of the School of Agriculture and Cockle Park (then Northumberland County Experimental Station, now owned by the College) from 1931 until 1947.

Hanley, who received his school education at Wakefield Grammar School, served later in the county of his birth and forbears as lecturer in agricultural chemistry and advisory chemist in the University of Leeds. Prior to this appointment he had obtained the degree of Ph.D., University of Munich, as well as becoming an associate of the Royal College of Science, for which he studied in London. Before going to Leeds he had been engaged in research at Rothamsted, and was Board of Agriculture Research Scholar during 1912–14. From Leeds he went as professor of agriculture and chief advisory officer in the University of Bristol, where he served from 1924 until 1927, whence he became principal of the Royal Agricultural College at Cirencester, where he continued during 1927–31. His appointment to the chair of agriculture at Newcastle—in succession to the famed Somerville, Middleton and Gilchrist—was made in 1931.

There is no doubt that he experienced much satisfaction from the opportunities afforded him in the scientific directorship of Cockle Park—an office which devolves on the professor of agriculture in King's College—for Hanley's major interest in agriculture was the subject of grassland management. As early as 1927 he was the joint author with Prof. R. G. Stapledon of the book "Grass Land : its Management and Improvement", published by the Oxford University Press, and in subsequent years he was responsible for the Ministry of Agriculture's well-known bulletin on "Grassland", as well as for several of the Ministry's leaflets on various aspects of the same subject. He was a leading spirit in the national campaign for grassland improvement, taking a prominent part as judge and adviser in the grassland competitions organized in the four northern counties of England during the early 'thirties.

While giving much attention to grassland, especially to the then recent developments in its utilization as dried grass and silage, in which subject he carried out early investigations at Cockle Park, Hanley had a wide knowledge of agriculture and agricultural education. In a volume of essays presented to Sir Daniel Hall on "Agriculture of the 20th Century", published in 1939, Hanley's fine contribution was a comprehensive study entitled "Agricultural Education in College and County".

Among his original contributions when at King's College was a survey of agriculture in the Northern Province (Counties Durham, Northumberland, Cumberland and Westmorland), made possible by a financial grant given by the Right Hon. David Lloyd George. Although this was a comparatively quick survey, the report published in 1936 gives an informative account of the agriculture of the area which for the purpose of the survey was divided into twenty districts ; Hanley being assisted in this extensive project by two of his students, Messrs. Boyd and Williamson.

As in the case of his predecessors mentioned in the chair of agriculture, King's College, he formed many mutually helpful friendships with northern farmers—as, for example, D. J. Brown of West Learmouth, and J. B. Barr of Pressen—the study of whose farms, and discussion of changes in management, resulted in his contribution to the *Journal* of the Royal Agricultural Society of England, entitled "Tweedside Farming Enterprises", which itself is a typical example of the wide range of subjects on which he wrote for various journals. In his latter years he was editor of a series of four volumes published by Caxton in November 1949, under the title of "Progressive Farming".

During the Second World War, from 1940 onwards, he became the Ministry of Agriculture's liaison officer for the northern counties in connexion with the food production campaign.

From my personal knowledge as a colleague for the period of his professorship at King's College, I knew him to be a very good teacher, whose courses of lectures on soils and geology are remembered. He showed a greatly appreciated interest in the social and athletic activities of his students, being *inter alia* a keen supporter of their Rugby achievements, to which a photograph (still hanging in the Dean's private room in the School of Agriculture) bears testimony showing him surrounded by members of the team. No one who knew him intimately could fail to be aware of his emphasis on efficiency and his keen interest in his work as a teacher and adviser on agriculture, and of his continuous desire to make his contribution to the progress of that distinctive movement in the present century towards the improvement in management of the grassland of Great Britain.

H. CECIL PAWSON

Dr. F. Jones

DR. FRANCIS JONES, T.D., died suddenly at Crowborough on February 28.

Francis Jones was born at Belper, Derbyshire, in 1887. He was educated at Wirksworth Grammar School, graduated at the University of London, and later took his Ph.D. in geology. He was commissioned as a lieutenant in the Royal Engineers during the First World War and served in France, Gallipoli and Egypt. He taught as a science master, first in Leicester and then from 1929 until 1947 at St. Dunstan's College, London, where he served as commanding officer of the Officers Training Corps for eight years. During this period he also acted as head of the Department of Geology at the Northern Polytechnic. Between 1926 and 1936 he published a number of papers on his researches on the petrology of the Pre-Cambrian rocks of Charnwood Forest.

His love of geology and young people coupled with his tremendous energy would not allow him to retire, and in 1947, at the age of sixty, he joined the staff of the Geology Department of the Imperial College of Science and Technology, where he remained until 1958 ; at the same time he continued until his death his teaching at the Northern Polytechnic. In the lecture theatre and the laboratory he was insistent on fundamentals. Influenced by his great friend, the late Dr. Alfred Brammall, he brought his knowledge of chemistry to bear on theoretical aspects of mineralogy and petrology, and his lectures and discussions on these topics were a stimulus to all those who were privileged to hear them.

Anxious to use every minute of his day, he turned the accumulated knowledge of his academic career to the problems of engineering geology, and from the age of sixty-one until his death worked during vacations as a consultant geologist on civil engineering projects in Syria, the Lebanon, Iraq, Iran, Ghana, the Sudan and on the Kariba Dam in Central Africa. His kind but rugged features were a true expression of his character. He possessed a physical toughness and endurance which were remarkable for a man of his age. Twenty miles a day on foot in the deserts of the Middle East or the bush of Africa left him undaunted; he invariably led the way. His only admission of physical discomfort was at the age of seventy, when he said that he felt somewhat sore after riding on horseback for two days through the Elburz Mountains of Iran.

Loyalty was the keynote of his personal life, and despite the failing health of his last two months he travelled to various parts of the country to fulfil lecture engagements regardless of the advice of his doctor and friends. It was his sense of loyalty supported by his great physical courage which carried him from his home at Crowborough to London to give his last lecture to his students at Northern Polytechnic ten days before he died.

D. J. SHEARMAN

Dr. August Gansser-Burckhardt

DR. AUGUST GANSSER-BURCKHARDT, who died on January 27 at his home in Basle, will be remembered by many for his achievements in fields on the borderlines of technology, and by his friends for his radiant personality. He was born in Milan in 1876. After passing the examination in chemistry at the Federal Technical College in Zurich, he obtained a doctorate at the University of Zurich in 1900. After one year's further study in London, Dr. Gansser began his life-long association with the family enterprise, the present S.A. Ledoga in Milan, manufacturers of vegetable tannins and natural dyes. It was at an opportune time, since Dr. Lepetit had just worked out his revolutionary process of making cold-water soluble quebracho extract by sulphitation. Gansser contributed substantially to the success of this venture. Since 1917, he had resided at the old home of his family, Basle, serving as the international co-ordinator for the family concern.

Along with his business activity, two major inquiries became gradually the all-absorbing interests in his life. His name will always be connected with the battle against the warble fly and with his contributions to the ancient history of leather. His fight for the eradication of the warble fly, which not only inflicts sufferings on cattle but also does a great deal of damage, resulting in much decreased value of the hides and impaired yields of milk and meat, made him well known throughout the world. His untiring efforts in this vital crusade were recognized by his Alma Mater by the award of the honorary degree of D.V.M. His second interest was archæology, particularly the study and analysis of finds from excavations of Roman settlements on the Continent and particularly of sites in Italy. His broad humanistic knowledge and his scientific training became a most effective combination in this pioneering research. He handled the archæological issues as well as the chemical analysis of the finds most competently.

Dr. Gansser was the founder of the Swiss Society of Leather Chemists, and he was instrumental in re-establishing international contacts after the two World Wars. At the time of the first one, he served as the president of the International Society of Leather Chemists.

Dr. Gansser was a man of wide culture, embodying the best traditions of his beloved Switzerland and Italy, and of kind and unassuming disposition. His sterling personality and his talents as a linguist and speaker—with five languages ready to his service—made him a well-known, and lately legendary, figure at international gatherings in his field of work for more than half a century.

K. H. GUSTAVSON

Mr. F. H. Edmunds

WITH the death of Francis Hereward Edmunds on April 19 at Westhumble, Surrey, British practical geology lost an exponent whose work had long been an encouragement to civil engineers and many other professional men seeking advice on geological problems. His friendly guidance will no less be missed by innumerable students, research workers, amateur geologists, naturalists and interested laymen in the south of England. Many will recall with pleasure the field excursions led by Edmunds and the lectures he was always pleased to give to promote popular understanding of the influence and application of geology. Most of all, however, he will be missed by his colleagues on the Geological Survey of Great Britain, where he served from 1922 until 1957 and was always happy to encourage the younger geologist.

Edmunds was proud to own himself a native of Wiltshire. He was born at Mere in 1893 and was educated at Gillingham Grammar School, in the neighbouring county of Dorset. After serving in France as a captain in the Tank Corps during the First World War, he went up to Emmanuel College, Cambridge, where he made many friends in the University. He obtained first-class honours in geology in Part II of the Natural Sciences Tripos in 1922.

Throughout his career on the Geological Survey, Edmunds maintained his strong interest in geological mapping. Large areas on a number of published 1 in. to the mile maps, notably in Surrey, are the result of this work, and Edmunds was part-author of the explanatory memoirs on the Reigate, Guildford and Romford districts. Among other official publications, he was author of "British Regional Geology: The Wealden District" and part-author of "The Central England District" in the same series. Edmunds compiled a memoir on "The Wells and Springs of Sussex", and published papers in the *Journal of the Institution of Water Engineers* and elsewhere. During his period in charge of a small unit formed at the Geological Survey in 1936 on the request of the Inland Water Survey Committee, Edmunds organized the systematic collection and collation of well-records and undertook many advisory duties for Government departments and the Services, particularly during the Second World War. During 1945–57 Edmunds was district geologist for South-Eastern England.

Perhaps the strongest appeal of his book, "Geology and Ourselves", lies in its treatment of aspects of civil engineering and geology in everyday life. Edmunds also wrote and lectured with authority on the geology of scenery, of soils and of building materials. He was president of the South-Eastern Union of Scientific Societies in 1949 and took an active part in the Geology Section at the British Association meetings of 1954 and 1955.

Among his activities after retiring from the public service, Edmunds continued to put his geological knowledge at the disposal of the community on questions of planning in the County of Surrey.

It is sad that the fatal recurrence of an illness he had suffered three years previously prevented Edmunds from enjoying longer a happy retirement in the beloved Mole valley where he had made his home since 1939. His wife and daughter will know that his memory will long be cherished in the Dorking and Mickleham district for his activities both as townsman and countryman, and the delight he took in music and musical affairs.

S. C. A. HOLMES

NEWS and VIEWS

Earth Satellite 1960ε

THE heaviest satellite yet to be placed in orbit about the Earth was launched from the U.S.S.R. at about 00 hr. U.T. on May 15. Its total weight, excluding the final stage of the rocket which took it into orbit, is 4,540 kgm. (10,010 lb.), more than three times as heavy as *Sputnik* 3, which was launched two years earlier. The satellite, which has been called *Korabl'-Sputnik* or space-ship satellite, consists of a pressurized cabin weighing about 2,500 kgm., which contains a dummy astronaut and all apparatus necessary to keep a man alive in space, together with extensive instrumentation, weighing about 1,500 kgm. The satellite carries various radio transmitters, with the main one operating on a frequency of 19·995 Mc./s. The chief purpose of the satellite is to test the design of the cabin, and the first measurements made by the instruments suggested that the environment in the cabin was suitable for human survival. It is stated that the cabin is to be detached from the remainder of the satellite ; it will then probably burn up in the atmosphere, since it is not designed to withstand re-entry.

The orbit of the satellite, like that of *Sputniks* 1, 2 and 3, is inclined to the equator at an angle near 65°. The initial period of revolution was 91·2 min., corresponding to a semi-major axis of 6,713 km., and the orbit was nearly circular, having an eccentricity of about 0 0048. The satellite was at perigee when going north at a latitude near 54° N., the perigee height being about 320 km. (200 miles) and the apogee height about 380 km. (235 miles). The lifetime of the satellite is uncertain, being dependent on conditions after the separation of the cabin, but does not seem likely to be more than a few months. At latitudes between 40° N. and 60° N. the satellite will be favourably placed for observation in the night sky during May and June. The final stage of the launching rocket separated from the satellite on entering orbit.

Cryptogamic Botany at Manchester : Prof. J. Colhoun

DR. JOHN COLHOUN, reader in mycology and plant pathology in the Queen's University, Belfast, has been appointed to the chair of cryptogamic botany in succession to Prof. C. W. Wardlaw, who now occupies the George Harrison chair of botany in the University. Though his published work lies in the fields of mycology and plant pathology, of which he is a distinguished exponent, Dr. Colhoun is also a botanist of wide experience. He entered the Queen's University of Belfast in 1930, graduated in science in 1933 and in agriculture in the following year. The next four years were spent in research at the Department of Agricultural Botany in Belfast and at the Imperial College of Science and Technology, London. He returned to Belfast in 1938 to the Department of Plant Pathology and from 1940 up to the present has held posts in the Departments of Agricultural Botany and of Mycology and Plant Pathology. Since 1939, he has held, concurrently with his University appointments, corresponding posts in the Plant Pathology Division of the Ministry of Agriculture of Northern Ireland. During 1942–49, Dr. Colhoun was warden of the Queen's Elms hall of residence for men in Belfast and has also held other University posts. During the past twenty-five years Dr. Colhoun's researches have been directly related to fundamental problems in plant pathology, particularly in relation to plant environment, the control of the diseases of economic plants, and the investigation of the physiology of various fungi. He has also co-operated with geneticists in a programme of breeding disease-resistant plants. He is the joint author of a book on "The Diseases of the Flax Plant", the author of an important monograph on "Club Root Disease of Crucifers" and of many contributions to scientific journals.

Physiology at the London Hospital Medical College: Prof. K. W. Cross

KENNETH WILLIAM CROSS, who has been appointed to the chair of physiology in the London Hospital Medical College, in succession to Prof. J. L. D'Silva (see *Nature*, 184, 405 ; 1959), entered St. Mary's Hospital as a Scholar soon after the outbreak of the Second World War. After qualifying, he held a research studentship in the Wright–Fleming Institute, and having obtained the M.R.C.P. spent the remainder of the War as casualty physician at St. Mary's and as resident physician to the E.M.S. Hospital at Amersham. After the War, he worked for a year with the Friends' Ambulance Unit in China and taught at Cheeloo University. On his return in 1947 he was appointed lecturer in physiology in St. Mary's Hospital Medical School and soon afterwards also clinical assistant on the Pædiatrics Unit of the Hospital. He then settled down to study respiration and metabolism in the new-born infant, and this has remained his principal interest. He devised an accurate method for determining the infant's respiratory movements and oxygen consumption, and made a special study of the effects of lack of oxygen. The value of his investigations was soon recognized by the Sir Halley Stewart Trust and by the Medical Research Council. In 1951 he became joint organizing secretary of the symposium on anoxia of the new-born infant, arranged in London under the auspices of the International Organization of Medical Sciences. He remained at St. Mary's, being appointed reader in human physiology in 1953 and reader in physiology in 1956, and obtaining the degrees of Ph.D. and D.Sc.

His work led to more basic studies of the mechanisms of respiration in new-born animals, pursued with Dr. June Hill at St. Mary's and with Dr. G. S. Dawes and his colleagues at the Nuffield Institute for Medical Research at Oxford. Cross spent last year in Dr. Julius Comroe's laboratory at the University of California Medical Center and developed a method for inflating the infant's lungs which led to the discovery of surprising reflex mechanisms and may have opened an entirely new field. His many physiological and pædiatrical friends look forward to further important contributions from the London Hospital Medical College.

Statistics at University College, London : Prof. E. S. Pearson, C.B.E.

At the end of the current session Prof. Egon Sharpe Pearson retires from University College, London, and for the first time in seventy-six years there will no longer be a Pearson in charge of the statistics at the Department there which has become world famous. Egon Pearson was educated at Winchester and Trinity College, Cambridge, and continued his studies in statistics at University College, London, where he became a lecturer in 1921. Not long afterwards Jerzy Neyman joined the Department, and before long he and Egon Pearson began a remarkable series of papers which effectively laid the foundations of the Neyman-Pearson theory of statistical inference, undoubtedly one of the profoundest influences on modern statistical thought. Pearson has continued to work in this field and the related area of confidence-interval theory and has notably advanced knowledge of the sample range. His work on the Ordnance Board of the Ministry of Supply during the Second World War was recognized by his appointment as C.B.E. in 1946. He has also taken particular interest in the teaching of statistics ; his work both at University College and as chairman of various committees of the Royal Statistical Society has laid both students and colleagues under a heavy burden of indebtedness to him for his constant endeavours to raise the standards of statistical instruction. He was president of the Royal Statistical Society during 1955–57 and received the Society's Gold Medal in 1955.

For about 25 years Pearson has been editor of *Biometrika*, and the high standing of that journal is largely due to his painstaking work and constant care. Another of his many contributions has been his work on statistical tables, embodied in the Pearson–Hartley "Tables for Statisticians, Part 1", and the *Biometrika* series of reprints. His many friends will be glad to know that he intends to devote a good deal of his time to continuing this work.

Prof. M. S. Bartlett

Prof. Maurice Stevenson Bartlett, professor of mathematical statistics in the University of Manchester, is to succeed Prof. Pearson. Prof. Bartlett read mathematics at Queens' College, Cambridge, and was awarded the Rayleigh Prize in 1934. After a short period as assistant lecturer at University College, London, and four years as statistician with Imperial Chemical Industries, Ltd., he returned to Cambridge as a lecturer in statistics in 1938. With the late John Wishart he helped to introduce modern statistical methods there and contributed some noteworthy research papers in a wide range of subjects : experimental design, factor analysis, regression theory and statistical inference. He was appointed to the chair of mathematical statistics at Manchester in 1947, and has worked there since that time. His principal contributions in more recent years have lain in two main fields, multivariate analysis and stochastic processes including time-series, both of them complicated and difficult subjects in which his work has given him a world-wide reputation.

Communication Research at Keele : Prof. Donald M. MacKay

The University College of North Staffordshire, Keele, has appointed Dr. Donald M. MacKay to the new Granada research chair of communication, founded by a gift of Granada Television Network, as from June 1, 1960. Dr. MacKay, who is at present reader in physics at King's College, London, graduated from the University of St. Andrews in 1943. After war-time work on radar with the Admiralty, he joined the staff of King's College, where he was concerned with the early development of information theory and the theory of 'brain-like' self-organizing information systems. On the experimental side, a period of research on the informational limits of high-speed analogue computing led to his present interest in the mechanism by which information is processed in the central nervous system.

The work at the University College of North Staffordshire is expected to develop along three main lines : (1) the study of perceptual mechanisms, and the development of methods for the analysis of electrical brain-activity in perception ; (2) the development of artificial mechanisms capable of identifying patterns in space or in time, as an experimental 'testing ground', for theories of perception ; (3) the study of disorders of function, as clues to the organization of the brain. Research on these interdisciplinary lines will require the collaboration of physiologists and experimental psychologists as well as of physicists and electronic engineers ; and the setting up of an independent University department at Keele for the purpose marks a significant step in the academic development of this new subject. Dr. MacKay's gifts as a research worker and a teacher will be sorely missed at King's College ; but we may surely look forward to a period of great activity and development in his new environment. In spite of his new responsibilities, we may also be sure that his interest in undergraduates and their problems will continue undiminished.

Principalship of Fourah Bay College : Dr. D. Nicol

Dr. Davidson Nicol has been appointed principal of Fourah Bay College, the University College of Sierra Leone, in succession to Mr. J. J. Grant. Dr. Nicol was educated at primary schools in Nigeria, the Government Model School, Freetown, and the Prince of Wales School, Freetown. In 1943 he entered Christ's College, Cambridge, having won an open Colonial scholarship for medicine. He was elected Foundation Scholar at Christ's College in 1946 and also in that year was the Open Universities Entrance scholar to the London Hospital. In 1947 he obtained first-class honours in the Natural Sciences Tripos and he graduated in medicine at the London Hospital in 1950. Dr. Nicol was awarded a Beit Memorial Fellowship for Medical Research in 1954, and when he became a Fellow of Christ's College, Cambridge, in 1957, he was the first African to be elected to a fellowship at either Oxford or Cambridge. During 1952–54 he was lecturer in physiology and biochemistry in University College, Ibadan, Nigeria, and has been guest lecturer in the University of Toronto and at a number of American universities. He is at present senior pathologist and head of the Laboratory Services of Sierra Leone.

Recruitment of Teachers in Britain

IN replying for the Government in an adjournment debate in the House of Commons on the supply of teachers of mathematics, which was opened by Mr. A. Skeffington and Mrs. E. White on May 9, the Parliamentary Secretary to the Ministry of Education, Mr. K. Thompson, said that a survey carried out in the schools in March 1959 showed that there are 5,100 people with honours degrees teaching mathematics in maintained schools, and 4,500 of these were in 2,600 maintained secondary schools with General Certificate of Education courses in mathematics or science, in which at that time there were 250 vacancies for honours graduates to teach mathematics. In these 2,600 schools there are also 3,250 non-graduate specialists teaching to General Certificate of Education standards. Mr. Thompson pointed out that of honours mathematics graduates from British universities, two-thirds already go into the educational system at some point and the universities are increasing their output. If the proportion recruited for teaching could be increased, this would be done. He also stated that during the period when teaching qualified a man for deferment from National Service, there was a net gain of about 500 honours graduates into the teaching profession, and that this modest gain had continued since 1957 when honours graduates had been completely free to choose between industry and the teaching profession. Mr. Thompson thought that the debate had not been completely fair to those coming from training colleges in Britain: he is confident that many of them are quite capable of teaching mathematical subjects and some of the sciences to Ordinary level General Certificate of Education standard with success, and some of them would be able to take these subjects at a higher level. Apart from his reference to attempts to attract more university graduates into the schools, Mr. Thompson stressed the need to attract more married women to come back into teaching either full-time or part-time, and he referred to the refresher and short courses in mathematics promoted by the Ministry, and to the 106,000 Ordinary level and 21,000 Advanced level passes from maintained secondary schools, compared with 71,000 and 13,000, respectively, in 1954.

British Books for Export

IN a written answer in the House of Commons on May 9, the Chancellor of the Duchy of Lancaster, Dr. Charles Hill, stated that the Advisory Committee on the Selection of Low-Priced Books for Export has made good progress, and he understood that the Committee will shortly recommend its first list from the 2,000 titles put forward by publishers and others to the Ministers concerned. The Advisory Committee is also studying a first list of some twenty-five scientific and technical text-books for issue in low-priced editions for university and college libraries, instructors and students. The Government has decided to give a measure of priority to university text-books in view of the importance attached by the Commonwealth Educational Conference to the supply of books of educational, scientific and technical value. Initially, the arrangement will be applied in India, and subject to negotiations with publishers, it is hoped that low-priced editions of text-books will be made available for distribution through normal trade channels in India by December next. The size of editions will depend upon demand, among other factors, but the Government has in mind editions of up to 5,000 copies of the more specialized and advanced university text-books.

Dental Research in Britain

IN answer to a question about dental research in the House of Commons on May 9, Mr. D. Walker-Smith, Minister of Health, as representing the Minister for Science, said that current annual expenditure on dental research by the Medical Research Council exceeds £35,000, and that at least one quarter of the annual expenditure of £750,000 of the university dentistry departments is spent on research. The Minister is not satisfied with the scale of dental research in Britain, and he attributes the position to lack of interest and enthusiasm on the part of dentists and graduates in science.

European Co-operation for Science

A MAJOR project in international co-operation in science education is to be launched as the result of an agreement signed between the Minister of Education and the Organization for European Economic Co-operation. The project will consist of a series of films aimed at stimulating the interest of young people in scientific subjects and made by a number of national organizations. The organizations are: the Educational Foundation for Visual Aids (United Kingdom); Institut Pedagogique National (France); Institut für Film und Bild (Germany); Statens Filmcentral (Denmark); Statens Filmsentral (Norway); Nederlandse Onderwijs Film (Holland). The contribution of the United Kingdom will be a film on 'Faraday' and the others are: "The Atomic Age" (Denmark); "Fight against Bacteria" (France); "Discovery of the Rare Gases" (Holland); "The Story of X-Rays" (Germany); and "The Story of Electrochemistry" (Norway). The scheme, initiated by the United Kingdom, received the full support of the national organizations represented on the International Council for Educational Films. It has been made possible by financial help from the Organization for European Economic Co-operation which is contributing half the cost, the remainder being provided by the national organizations already mentioned. The project will be organized by the Educational Foundation for Visual Aids. When complete, the films will be available to all schools in the member countries of the Organization for European Economic Co-operation.

The Association of Universities of the British Commonwealth

THE report of the Executive Council of the Association of Universities of the British Commonwealth for the year ended July 31, 1959, includes the usual particulars of appointments in which the Association was asked to act in one way or another (pp. 28. London: Association of Universities of the British Commonwealth, 1959). These totalled 720, compared with 651 in 1957–58, and the office dealt with 4,896 inquiries, of which 4,260 related to advertised appointments. Eighty advisory committees were convened and reports sent to the universities concerned on 139 candidates. Of the 115 candidates making application through the Association whose appointment was announced by member universities, eighty were in Australia. Membership of the Association now comprises 102 universities, 15 university colleges and 4 other institutions, and some notes on the meetings of the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom are appended to the report.

Fuel Abstracts and Current Titles

THE annual report of the Council for the Institute of Fuel for the year 1959 makes reference to a new publication that will be called *Fuel Abstracts and Current Titles* (The Institute of Fuel. Report of the Council and Statement of Accounts for the year 1959. Pp. 16. London: Institute of Fuel, 1960). The first number is expected to be issued in mid-May. With the changes that took place in the reorganization of fuel research following the cessation of the activities at Greenwich of the Fuel Research Board, the Department of Scientific and Industrial Research had ceased to publish the most successful series of abstracts known as *Fuel Abstracts*. It was recognized by many fuel interests that the entire disappearance of the undertaking should not be allowed to occur, and therefore efforts have been made by the Institute to keep the venture alive. The problem has been to find the necessary financial support, and the Council of the Institute now announces that such further support has been promised for a period of development to a self-supporting stage to an extent to justify the Institute in undertaking the responsibility of publication. One of the major problems of modern technological development is that of keeping in touch with the really important scientific advances. Accordingly, the function of such an undertaking is invaluable. This is particularly the case since one of the weaknesses of our modern scientific activity is the amount of repetitive work that is done, mainly because the records of past achievements have not been adequately reported, or that the investigators themselves have not been able to consult the volumes in which the work was originally reported. In other words, in the battle for progress our lines of communication have been weak. In the present context the moral is obvious, and it is hoped that the new venture will supply the necessary strength.

Journals and the Science of Glass Making

DURING the forty-three years of its existence, the *Journal of the Society of Glass Technology* achieved world-wide recognition as the leading publication in its field; this pre-eminence was due, in no small measure, to Emeritus Prof. W. E. S. Turner, who was editor for thirty-five years and a leading contributor to its pages. It is fitting that Prof. Turner should have been invited to write a foreword to the twin offspring of 'his' journal. Of recent years, glass-making—and for that matter the related industry of ceramics—has become firmly based on fundamental science applied through a complex technology. New work for the glass industry has become increasingly varied and the Society of Glass Technology has decided to distinguish between that which is technological and that which is more a matter of pure chemistry and physics; papers of the former type will in future appear in *Glass Technology*, papers of the latter type in *Physics and Chemistry of Glasses*. In the first issue of *Glass Technology* there are articles on glass-furnace refractories and on glass-making machinery (1, No. 1; February 1960 Pp. xl+68. Published bi-monthly. 25*s*. per issue or 135*s*. per volume). *Physics and Chemistry of Glass* contains papers on the strength of glass-fibres, the viscosity of sodium germanate glasses, the structure of boric oxide and borate glasses, and the change in the hardness of some simple glasses with increasing temperature (1, No. 1; February 1960. Pp. 54. Published bi-monthly. 25*s*. per issue or 135*s*. per volume). Each journal carries its own collection of appropriate abstracts. Both are edited by Prof. R. W. Douglas, who is to be congratulated on their excellent lay-out and presentation. A joint annual subscription can be obtained at 200*s*.

Cytology

A NEW Russian journal is to be devoted to cytology (*Cytology*, 1, No. 1. Editor in chief, A. S. Troshin. (In Russian.) Pp. 140. Moscow: Akademii Nauk SSSR, 1959). 'Cytology' is regarded for this purpose as encompassing a rather wide field, including nerve and muscle physiology and radiation biology, for example, as well as more narrowly cytological topics. It seems clear that there is at the present time in the Soviet Union a considerable expansion of effort and widening of interests, so far as studies at the cellular and sub-cellular levels are concerned. The recognition in the editorial preface of *Cytology* of the fact that contributions from the U.S.S.R. have lagged behind foreign work in some fields of cytology (especially in sub-microscopic structure, cytogenetics and cytochemistry) is unfortunately underlined to some extent by the contents of several of the papers in the first issue. The future development of cell biology in the U.S.S.R. will be watched with a great and friendly interest. It is therefore very much to be hoped that, until such time as a complete translation service is available for this journal, there will be included, in addition to the present contents list in English, an English summary of each paper in future issues.

Russian Journal of Physical Chemistry

THE Chemical Society, in co-operation with the Department of Scientific and Industrial Research, is issuing a translation of the *Russian Journal of Physical Chemistry*, beginning with the Russian July 1959 issue. The English version appears about three months after the Russian, and each part contains about twenty illustrated papers and shorter notes. The English editor is R. P. Bell. Each number is of about 112 pages, 8½ × 11 in., in covers. Most of the papers are quite short and a wide field of interest is covered. Much very good work in physical chemistry has been appearing in the U.S.S.R. (the tradition goes back over a long period of time) and chemists generally will be glad to have this translation available. The print is clear. The symbols in the mathematical equations are rather small, although they are clear. It is noticed that Russian translations of English and American works are referred to instead of the originals. The price of the first eighteen monthly issues (corresponding with the Russian issues for July 1959–December 1960) is £45 or 135 dollars, with a reduction of 25 per cent for colleges and universities. Thereafter, the annual subscription, beginning with the Russian January issue, will be £30 or 90 dollars, with the same reduction. The world distributors are Cleaver-Hume Press, Ltd., 31 Wright's Lane, London, W.8, from whom further information can be obtained.

Document Micro-reproduction

"MICROTEXTS as Media for Publication" (Hertfordshire County Council Technical Information Service, Hatfield. 9*s*.) records the papers and discussion of a symposium held at Hatfield Technical College in November 1959. The organizers are to be congratulated on getting as main speakers three of the best known names in the microtext field—Mr. Eugene Power, of University Microfilms, Inc., who spoke about successes achieved with microfilm, particularly in the academic field; Dr. L. J. van der Wolk, director of the library of the Delft Technical University, on the increasing use of microfiche (that is to say, flat film, 75 × 125 mm. or 90 × 120 mm., containing 8–100 pages); and Mr. C. D. Gelatt, on the 'Microcard'. The experts in three forms of document micro-reproduction have not previously been heard together in Great Britain, and it is noticeable that there is no feeling of competition between them; each believes that there is a place for his particular form of microtext. The booklet also reproduces a delightful talk given in London early in 1959 by Fremont Rider, whose book, "The Scholar and the Future of the Research Library", originally published in 1944, suggested 'Microcards' to the library world. The idea was taken up by Mr. Gelatt, who was and is an industrialist in Wisconsin. He endowed the Microcard Foundation with 100,000 dollars, and the success of the idea is apparent when we remember the millions of 'Microcards' being made for the International Geophysical Year and the Atomic Energy Commission. (This booklet's 88 pages are reproduced on two 'Microcards' placed in a pocket on the inside of the back cover.) The pamphlet will be of great interest to librarians and others concerned with the newer ways of publishing and photocopying.

Radiochemistry of the Elements

THE Subcommittee on Radiochemistry of the Committee on Nuclear Science of the United States National Academy of Sciences (National Research Council) is sponsoring a series of monographs on the radiochemistry of the elements, three volumes of which, on cadmium, arsenic and francium, have now been issued (National Academy of Sciences—National Research Council. Subcommittee on Radiochemistry. NAS-NS-3001: The Radiochemistry of Cadmium. By James R. DeVoe. Pp. vi+57. 75 cents. NAS-NS-3002: The Radiochemistry of Arsenic. By Harold C. Beard. Pp. vi+27. 50 cents. NAS-NS-3003: The Radiochemistry of Francium. By Earl K. Hyde. Pp. vi+34. 50 cents. Washington, D.C.: Office of Technical Services, Department of Commerce, 1960). It is expected that about fifty volumes will be issued within the next six months.

Preventive Aspects in the Teaching of Pathology

IN the past the practice of medicine was almost wholly, if not altogether, confined to the treatment of patients. Nowadays, the doctor is often called upon to apply his knowledge for the prevention of disease. This change in medical practice is being increasingly recognized by the medical schools with the introduction of preventive medicine and social medicine into the curriculum, not as an isolated subject, but as one integrated with the other disciplines. In 1957 a Study Group was convened by the World Health Organization to consider how the preventive aspects of medicine could be introduced into the teaching of physiology. A similar task has now been undertaken for pathology by the Expert Committee on Professional and Technical Education of Medical and Auxiliary Personnel (World Health Organization. Technical Report Series No. 175: Preventive Aspects in the Teaching of Pathology—Seventh Report of the Expert Committee on Professional and Technical Education of Medical and Auxiliary Personnel. Pp. 30. (Geneva: World Health Organization; London: H.M. Stationery Office, 1959.) 1 Swiss franc; 1*s*. 9*d*.; 0.30 dollar). In its report, the Committee points out that the essential task of the teacher of pathology in promoting the concept of prevention is to trace the complete evolution of lesions, paying special attention to their causation, their progressive development, and the disturbances in function that they bring about. He is in a particularly advantageous position to show the stages in the progress of the disease at which the changes are still reversible, and so the limits beyond which efforts at prevention and cure become increasingly less effective.

Semiconductor Components

THE front cover of the 1959 annual report of Texas Instruments, Inc., consists of a full colour photomicrograph showing the crystal structure of a high-purity bismuth telluride bar made during thermoelectric experiments in the Texas Instruments Central Research Laboratories (Texas Instruments, Inc. Annual Report, 1959. Pp. 20. Dallas: Texas Instruments, Inc., 1960). The report states that during 1959 the company continued its pattern of rapid growth and improvement of operations, with an increase of 110 per cent in sales and 136 per cent in net income over the previous record. The total personnel increased from 7,500 to 15,000. Three new buildings were completed on the 300-acre estate in North-east Dallas, and an addition to the semiconductor-components plant and a building for the manufacture of basic semiconductor and other materials are under construction. During September the construction of a new 120,000-sq. ft. plant was begun at Bedford, England, for Texas Instruments, Ltd., a subsidiary company, which manufactures semiconductor devices for the markets of the United Kingdom and Western Europe The plant will be completed late this year and will augment the 35,000-sq. ft. factory now in use. The work of the Metals and Controls Division and of the Geosciences and Instrumentation Division is briefly described and illustrated in the report. In addition, the revolutionary new solid circuit semiconductor introduced in March 1959 is discussed. This product represents a new approach to electronic circuitry and component miniaturization, providing an entire circuit in a single-crystal semiconductor slab no larger than a match head. Nearly a dozen different types of circuits have already been produced and many more can be constructed using the existing techniques. The first applications are to computers, missiles, rockets and space vehicles.

Acoustic Tiles for Noise Control

IT is sometimes possible to make considerable improvements by controlling noises at their sources. In the many cases where this cannot be done, sound-absorbing materials can be used to reduce noise to an acceptable level. Investigations in the Architectural Physics Section of the Division of Building Research of the Commonwealth Scientific and Industrial Research Organization, Highett, Victoria, have made it possible to determine the characteristics of sound-absorbing materials. The information obtained has enabled the Section to assist Australian firms in the design and manufacture of acoustic tiles and other sound-absorbing materials (*Industrial Research News*, 19 ; January 1960). In offices, halls and houses extensive use is made of acoustic tiles. These are relatively costly, but have substantial advantages over most other sound absorbers in both appearance and performance. A typical tile consists essentially of a perforated facing of metal or plaster and behind this a blanket of fibrous material, such as mineral wool. In Australia, tiles of this kind, with plaster facings, have become well known and are used to a greater extent than in most countries. With the growing demand, the number of firms producing acoustic tiles has increased considerably in the past few years and the Division has received many inquiries concerning their design. Dr. W. K. Lippert and Mr. W. Davern have been concerned both with research on the basic characteristics of sound-absorbing materials and with tests on products submitted by manufacturers.

Snow Loads and Roof Designs

In Canada, the heaviest load for which the roof of a building must normally be designed is the load imposed by snow. The magnitude of the design snow-load is thus of considerable importance. It must be high enough to reduce the probability of failure to an acceptable level, but not so high as to result in unreasonable construction costs. Snow loads to be expected in different locations across Canada are given in the National Building Code. These loads are based directly on measurements of maximum ground snow depths over a number of years and are generally considered to meet the requirements of safety. Appreciating the influence of design snow-loads on the cost of construction, the National Research Council Division of Building Research decided to undertake a study of the actual accumulations of snow, ice and rain on roofs as well as on adjacent ground. It was realized that this study must be carried out for a number of years and take into account the whole of Canada. Before embarking on this project, a pilot survey was conducted during the 1956–57 winter. Its results showed that a country-wide survey of actual snow loads on roofs would yield useful information, and that the proposed method and apparatus used would, with a few changes, be suitable for the full survey. More detailed investigations have since been carried out in successive winters, each time increasing the number of locations. A more detailed report of these investigations is to be found in the February issue of *Discovery*.

Organic Acid Synthesis in Tomato Roots

In studies of metabolism in tomato roots, J. van Die has ascertained that carboxylic- and amino-acids are synthesized in the roots and translocated to aerial regions of the plant (*Koninkl. Nederl. Akad. Wetens., Proc.* C, 62, No. 5, 504 ; 1959). In experiments in which potassium bicarbonate-^{14}C was supplied to the roots of plants in sand culture, he found that a few minutes after supplying the tracer to the roots, labelled organic compounds could be detected in the bleeding sap. After about 15 min. the secretion of active compounds reached its maximal rate, which was maintained for several hours. Analyses of the bleeding sap showed that most of the activity was present in the organic acid fraction, with malic acid as main constituent, followed by citric acid and a number of still unidentified acids. About 15 per cent of the activity was localized in amino-acids, and a small amount in α-ketoglutaric acid. In the roots the largest part of the activity was found in the organic acids and α-ketoglutaric acid, while only small amounts of active amino-acids were present. About 10 per cent of the activity of the roots was localized in proteins.

Geological Society of London

At the annual general meeting of the Society, held at Burlington House on April 27, the officers and Council for the ensuing year were elected, as follows : *President*, Prof. S. E. Hollingworth ; *Vice-Presidents*, Mr. A. J. Butler, Mr. T. C. Nicholas, Sir William Pugh, Dr. C. J. Stubblefield ; *Secretaries*, Mr. J. M. Edmonds, Dr. P. A. Sabine ; *Foreign Secretary*, Prof. O. T. Jones ; and *Treasurer*, Mr. P. Evans. *Council Members*, Prof. J. G. C. Anderson, Dr. H. W. Ball, Prof. O. M. B. Bulman, Mr. A. J. Butler, Prof. K. C. Dunham, Mr. J. M. Edmonds, Mr. P. Evans, Prof. T. N. George, Prof. W. D. Gill, Dr. D. R. Grantham, Prof. S. E. Hollingworth, Dr. R. G. S. Hudson, Prof. O. T. Jones, Prof. B. C. King, Dr. W. S. McKerrow, Mr. T. C. Nicholas, Sir William Pugh, Dr. Dorothy Rayner, Dr. P. A. Sabine, Prof. R. M. Shackleton, Dr. C. J. Stubblefield, Prof. J. Sutton, and Prof. P. C. Sylvester-Bradley.

Seventh Commonwealth Entomological Conference

The seventh Commonwealth Entomological Conference will be held in London during July 7–16, delegates to it being nominated by the Governments of the various countries of the Commonwealth, including many of the Colonial Territories. The proceedings of the Conference will include a number of open meetings, to be held in the Memorial Hall of the Royal Geographical Society (Exhibition Road entrance), South Kensington, London, S.W.7, on July 7, 8, 11, 12 and 14, and these will be open to all entomologists and others who may be interested, whose participation in the discussions will be welcomed. At each session a subject of wide interest to economic entomologists will be introduced by one or more invited speakers. The subjects are as follows : recent developments in insecticides for crop protection ; problems of applying insecticides ; hazards and precautions associated with the use of pesticides ; research on stored-products pests and their control ; biological control of insects and weeds ; insect attack in relation to the physical characters and physiological state of the plant ; investigations on timber-boring beetles ; termite control in afforestation projects and constructional timbers ; pathogenic organisms for the control of insect pests ; current trends in the study and control of tsetse flies and of locusts ; studies of dispersal of insects in relation to their control ; developments in the study of plant viruses and their vectors ; the link between research and its application in the field of plant protection. Programmes giving full details will be available about four weeks before the Conference from the Director, Commonwealth Institute of Entomology, 56 Queen's Gate, London, S.W.7.

University News : Cambridge

Matriculation requirements are to be modified. Each candidate will be required to hold the General

Certificate of Education (Ordinary Level) in the use of English, two languages other than English, mathematics or a science subject, and one other subject; in addition, two passes at Advanced Level in approved subjects will be necessary. Thus, the classical languages, and in particular Latin, are no longer compulsory subjects.

The Night Sky in June

FULL moon occurs on June 9d. 13h. 02m. U.T., and new moon on June 24d. 03h. 27m. The following conjunctions with the Moon take place: June 10d. 07h., Jupiter 5° S.; June 11d. 10h., Saturn 4° S.; June 18d. 19h., Mars. 2° N.; June 22d. 04h., Aldebaran 0·5° S. In addition to these conjunctions with the Moon, Mercury is in conjunction with Pollux on June 20d. 05h., Mercury being 6° S. Mercury is an evening star, visible low in the west after sunset; it sets between one and two hours after the Sun. Venus is too close to the Sun for observation. Mars rises at 1h. 50m., 1h. 15m. and 0h. 35m. at the beginning, middle and end of the month, respectively; it is in Pisces on June 1 and moves into Aries on June 20. Its stellar magnitude is + 1·0 and its distance from the Earth on June 15 is 151 million miles. Jupiter rises at 21h. 30m., 20h. 30m. and 19h. 30m. on June 1, 15 and 30, respectively, and sets at 3h. 10m. on June 30; it is thus above the horizon throughout the hours of darkness. It is in Sagittarius, its stellar magnitude is − 2·2, its distance from the Earth in the middle of the month is 400 million miles, and it is in opposition on June 20. Saturn is also in Sagittarius, rising at 22h. 35m., 21h. 35m. and 20h. 35m. on June 1, 15 and 30, respectively. Its stellar magnitude is + 0·4 and its distance from the Earth on June 15 is 845 million miles. There are no occultations of stars brighter than magnitude 6 visible at Greenwich. The summer solstice occurs on June 21d. 10h.

Announcements

PROF. D. G. CHRISTOPHERSON, professor of applied science in the Imperial College of Science and Technology, London, has been appointed warden of the Durham Colleges in succession to Sir James Duff, who is retiring.

DR. MILO P. HNILICKA has been appointed to the new post of scientific assistant to the vice-president and director of research for the National Research Corporation of the United States. Dr. Hnilicka will act as scientific advisor to the director of research and as a consultant on a number of projects now under way. His assignments will include technical liaison on new projects between the National Research Corporation and other laboratories in the United States.

A DINNER in honour of Mr. F. Howarth, on the occasion of his retirement from the Botany Department, Imperial College of Science and Technology, will be held on July 15 at the College. Old students who wish to attend this dinner, and who have not already been invited, should write as soon as possible to Dr. A. J. Rutter or Dr. R. K. S. Wood, Imperial College, London, S.W.7.

THE University of Maryland is to receive a grant of 216,000 dollars from the U.S. National Aeronautics and Space Administration to accelerate its programme of basic research dealing with the growth and metabolism of unicellular algae. Since 1949 personnel in the University's Department of Botany under the direction of Dr. Robert W. Krauss, professor of plant physiology, have been engaged in fundamental studies on the physiology of algae.

THE sixteenth International Congress of Zoology will be held in Washington, D.C., during August 21–27, 1963, under the presidency of Dr. Alfred S. Romer, Alexander Agassiz professor of zoology and director of the Museum of Comparative Zoology, Harvard University.

AN international conference on "Science in the Advancement of New States" is to be held in Israel during August 15–30 under the auspices of the Weizmann Institute of Science Further information can be obtained from the Scientific Attaché, Embassy of Israel, 2 Palace Green, London, W.8.

A CONFERENCE on "The Chemical Organization of Cells: Normal and Abnormal" will be held at the University of Wisconsin, Madison, during August 25–27. Further information can be obtained from Dr. J. F. A. McManus, Department of Pathology, University of Alabama Medical Center, Birmingham, Alabama.

THE seventh international conference of the Society for Biological Rhythm will be held at Siena, Italy, during September 5–7 in conjunction with the International Basimetric Society. Further information can be obtained from Dr. A. Sollberger, Department of Anatomy, Caroline Institute, Stockholm 60.

THE tenth Pacific Science Congress of the Pacific Science Association will be held in the University of Hawaii, Honolulu, during August 21–September 6, 1961. It will be sponsorod by the U.S. National Academy of Sciences and Bernice P. Bishop Museum, Honolulu, with the co-operation of the University of Hawaii. Scientific sessions will be held during August 21–September 2, with a post-sessional field-trip until September 6.

THE fifteenth Calorimetry Conference will be held at Gatlinburg, Tennessee, during September 7–10. Among the topics to be considered are: precision reaction and bomb calorimetry, solution calorimetry, microcalorimetry, heat-capacity measurements at low and high temperatures (0·1–1,400° K.); temperature scales and standard calorimetric samples, etc. Those wishing to attend or to present a paper should write to Dr. J. P. McCullough, Bureau of Mines, Box 1321, Bartlesville, Oklahoma.

THE Royal Meteorological Society is organizing a two-day meeting to be held at Queen's College, Dundee, during June 29–July 1. The meeting will take the form of two symposia, namely: "Convection" (June 30); and "Agricultural Meteorology" (July 1). Contributors to the symposium on convection include F. H. Ludlam (Imperial College of Science and Technology), C. Dixon (Queen's College, Dundee), F. W. G. Warren (University of Sheffield) and R. P. Peace (Queen's College, Dundee). Contributors to the symposium on agricultural meteorology include H. L. Penman and J. L. Montieth (Rothamsted Experimental Station) and G. J. Day and R. W. Gloyne (Meteorological Office).

ERRATUM. In the article entitled "A Synoptic Study of Infra-Red Radiation over the United States" by Dr. J. L. Gergen and Dr. W. F. Huch (*Nature*, May 7, p. 426), the units are printed incorrectly as "MW."; they should be "mW.".

THE SERENGETI NATIONAL PARK

By Dr. A. S. THOMAS

THE magnificent film "Serengeti shall not die" is not only pictorially beautiful but also scientifically fascinating. The film shows that the game animals amount to only about 367,000 instead of the million previously estimated; it shows that the migration routes lie outside the southern boundaries of the National Park, and that none of the herds goes near the area to the north, proposed as an extension of the Park; and it shows how the grasses were being investigated to discover the preferences of the antelopes.

The film itself goes far to answer the grass question; much of that on which the antelopes were grazing appeared to be *Themeda triandra*, but, whatever the species, the grass was always short, less than 2 ft. high and often reduced by fire or grazing to a few inches. Not only do antelopes like short grass for grazing but also they need it for observation of their predators, the lions and hyenas.

Prof. W. H. Pearsall recommended in his report[1] "That arrangements be made for the early exclusion of pastoral occupation from the National Parks" and that recommendation was adopted by the Board of Trustees of the Park in its 1957–58 report. Have trials been made to discover what will happen to the Serengeti grassland if it is protected from fire and from grazing? Much of it would probably grow to 6 ft. or more, much too tall to suit the smaller antelopes.

Some indication of what will happen may be seen in other places; I will mention two of them. The first place is the Gulu elephant sanctuary in Uganda, where the grass of the uninhabited area is up to 9 ft. high and is almost deserted by antelopes, which swarm on the shorter grazing lands at the edge of the sanctuary. The other place is the National Park in the Belgian Congo, east of Lake Edward, from which the sparse pastoral population was moved, with the result that the grassland grew so tall and coarse that the population of antelopes was much reduced. "Man certainly is an important member of the biome in Africa; human settlement is not, as might be imagined, solely antipathic to the increase of wild animals; the pastoral tribes, by controlled burning, produce flushes of grass which benefit not only their stock, but also the wild animals as well"[2].

As I have visited the Serengeti only once, I do not know it well, but I can think of no difference in the soil to account for the migration of antelopes outside the southern boundary of the National Park; it must be that the grass there is shorter, as they prefer it. Similarly, the area north of the Park, and suggested for inclusion in it, may well be avoided by game animals because it has little human population, little grazing by cattle, and the grass is therefore too long for the antelopes.

Prof. Pearsall noted the over-grazing and erosion from the flocks and herds of the Masai: "Even where the Masai cattle alone are using the grasslands there is evidence of grassland deterioration and it seems clear that it would not be possible for both cattle and game to occupy the same areas permanently". But, if there were more sources of water, more frequent movement of the stock, might there not be less erosion, less competition for grazing near the water holes?

The area of the Serengeti National Park is about 5,000 square miles, or 3,200,000 acres. The Masai cattle number about 120,000, sheep and goats about 220,000, donkeys about 6,000 (ref. 1). It is usually accepted that about eight grazing sheep or goats may be reckoned as equal to one ox; therefore, the total livestock of the Masai may be considered as about 150,000 units; there are about 3,000,000 acres of grazing, so there are about twenty acres of grazing for each head of cattle.

The soil analyses in Prof. Pearsall's report show good supplies of bases; there seem to be no marked deficiencies as in the acid grasslands to the west of Lake Victoria. The average rainfall of the National Park is about 30 in. a year; there is a dry zone near the eastern volcanic hills, but the hills themselves have more precipitation. As the Serengeti is near the equator, the rainfall is fairly well distributed, with two dry seasons and two wet seasons each year.

Under such conditions, is it not reasonable to expect that, with correct management, the Serengeti plains could support both the Masai stock and the game animals (a large proportion of which are small antelopes) without undue damage to the grass and the soil? It has long been evident that the management of the large open plains, and not the management of fenced pastures on European farms, is the main problem of grassland research in East Africa; that point was emphasized at the first East African Grassland Conference, held nearly twenty years ago. In spite of deficient knowledge about the management of the plains, of possible difficulties in arranging supplies of good water by dams and boreholes, yet it should be possible to preserve the grass and the game without displacing the Masai who are living in the area.

Scientists should be grateful to the Fauna Preservation Society, which arranged that Prof. Pearsall should visit Serengeti and made a comprehensive report on problems which had been given little definite scientific study; they should be grateful to Dr. Grzimek for all he did at his own expense; but above all they should be grateful to gallant young Michael Grzimek, who gave not only his money, but also his life, to this work.

With the rising tide of African nationalism, is there not a danger that we may be thought to devote too much attention to the animals of Africa and not enough to the people? David Howarth[3] has directed attention to the disparity of publicity about "Operation Noah", in which four or five thousand animals were taken to safety, and the plight of fifty thousand Batonga people who had to leave their homes before the flood of the Kariba Dam. Must we not make it clear that we are more concerned with the welfare of African peoples than of African animals?

May not the future of the animals be more secure if the Masai continue to live in the National Park of a self-governing Tanganyika? Is there no risk that an African Government will not look favourably on a large tract from which the Africans have been displaced and which to them seems reserved for animals and for American and European tourists?

If the National Park is preserved from fire and from grazing, the grass may soon be too long for the antelopes, which will go to the grazed land outside the reserve and fall a ready prey to poachers. Despite the lack of present knowledge, there must be an attempt to secure a balance of grazing which will suit both domestic stock and wild animals. The Masai are a proud and a conservative people; but they love their cattle and, if it were shown that measures were designed to maintain their herds in their present numbers, in their present homelands, I think they would co-operate.

---

THE WATHEROO MAGNETIC OBSERVATORY, MELBOURNE

WATHEROO Magnetic Observatory was established in 1919 by the Carnegie Institution of Washington, at a site about 110 miles north of Perth, Western Australia, and about 50 miles from the coast. Since that date the Observatory has carried out a programme of observations in terrestrial magnetism and electricity and ionospheric research. In 1947, the Observatory was transferred by gift to the Australian Commonwealth Government, and the Commonwealth Bureau of Mineral Resources, Geology and Geophysics has operated and maintained the Observatory since then.

In recent years there has been great difficulty in maintaining Watheroo Observatory as a residential establishment; so much so that consideration had to be given to moving the Observatory to suitable sites near Perth, where it would be possible to continue observations, and at the same time avoid the expense and staffing difficulties associated with the maintenance of a residential establishment in a remote locality. It was also believed that work of the Observatory would benefit from bringing the staff in closer contact with scientific workers at the University and other establishments in Perth.

In 1955, a site was selected in the Gnangara Pine Plantation, north of Perth, for magnetic observations, and another in the vicinity of Mundaring Weir, 20 miles east of Perth, in the Darling Ranges, for ionospheric and seismological observations. A site for an office and laboratory was selected in Mundaring township. When selecting observatory sites, the Bureau sought and was guided by the advice of many local and overseas scientific authorities.

The magnetic station was completed at Gnangara late in 1956, and observations and recordings began at that station in parallel with those at the Watheroo Observatory in July 1957. Both stations were operating throughout the International Geophysical Year.

The buildings at Mundaring necessary for the transfer of ionospheric observations from Watheroo have now been completed. A new ionospheric recorder has been purchased and will be installed soon. Magnetic observations and recordings ceased at Watheroo on January 31, 1959, and on March 18, 1959, the other observatory activities were transferred to Mundaring. Seismological recording began at Mundaring in August 1959, using a three-component Benioff seismograph, with both long- and short-period galvanometers.

The new organization is known as Mundaring Geophysical Observatory, with headquarters in Mundaring township. The magnetic and ionospheric data are distributed on the same basis as for Watheroo, and seismological bulletins are issued on the same basis as for other stations operated by the Bureau.

For the particular scientific observations undertaken, the transfer from Watheroo to Mundaring will have no significant influence on the results. The move of about 100 miles is not important on the global scale. It is believed that, although Perth Observatory has operated seismographs for many years, the new Observatory will fill a real need for a high-sensitivity seismograph in this area.

Further information concerning the new establishment should be addressed to the Observer-in-Charge, Mundaring Geophysical Observatory, Mundaring, Western Australia.

THE LE PLAY SOCIETY

FOUNDED in 1930 to encourage international studies along the lines advocated in the middle of last century by the French sociologist Frederic Le Play, the Le Play Society, under the direction of Miss Margaret Tatton, has for thirty years organized an annual 3-day conference and study visits to the less-familiar regions of Europe and North Africa. The formula for the overseas work was for a group with varied backgrounds to spend a few days getting the general 'flavour' of a country and then to settle down in a village to make an intensive study of the community and its environment. In the evenings geologist, botanist, agriculturist, geographer, sociologist, doctor, teacher would meet to pool their findings and, under expert visiting and local guidance, compare notes to build up a remarkably complete picture. About a dozen such studies reached a wider audience through publication as monographs.

On April 9–12, 1960, the Society met for the last time at Wadham College, Oxford, and Sir John Russell delivered his twenty-third annual address as president. Rather than face a slow decline, the Society decided to terminate its work in a blaze of glory—the final conference dealt with "Present Problems in World Affairs", with contributions from many angles by Prof. L. F. Rushbrook-Williams (India and Pakistan), Prof. A. L. Goodhart (International Law), Sir Reader Bullard (Middle East), Prof. L. Dudley Stamp (Food and Population), Dr. F. M. Brewer—now mayor of Oxford (Science and the Ordinary Man), Mr. William E. Abraham of All Souls (African Independence), Prof. E. M. Hugh-Jones (America:

The Influence of Affluence), Mr. E. Paget (West Indies), and Mr. N. H. Leyland (Economic Problems). Old friends who assisted in this final conference included Prof. H. J. Fleure, who presented to the president a handsomely bound volume including typescripts of his series of annual addresses, Sir Richard Livingstone, who took the chair at the presidential address, Prof. Kenneth Mason and more than a hundred members, who paid tribute in the form of a presentation to mark the devoted work of Miss Tatton.

The main reason for the decision to wind up the Society is a tragic commentary on the post-war world. While international tourism is being encouraged, study groups which moved so freely and were accorded unstinted help everywhere in the inter-war years are now faced with official frustration and danger of arrest as spies if they attempt to see anything not on the accepted tourist routes. In addition, increasing costs have placed such journeys beyond the resources of younger people who, if they can get grants, are required to attend meetings in their own specialisms. Few seem to have leisure for the quiet exchange of views with workers in other fields. Le Play methods in social and regional survey have, however, become basic requirements in physical and social planning all over the world.

L. Dudley Stamp

THE LACK OF THINKING IN EXAMINATIONS

In marking examination scripts, Dr. Margaret Sutherland, lecturer in education at the Queen's University, Belfast, has noticed that many students do not deal with the topic set (*The Universities Review*, 32, No. 7; February 1960). This occurs mainly in subjects which require a basic knowledge (of facts, or of a book, theory, or other works) and some more or less intelligent discussion of some aspect of this basic knowledge. The examiner has attempted to set a question which will differ from those set in previous papers and yet allow the students to display knowledge, select relevant data and comment reasonably thereon. To this, many students pour forth a statement of basic knowledge which is mostly without relevance to the question set.

Some examiners would classify this behaviour as 'examination technique' or conscious bluffing on the part of the students who, knowing that they are unlikely to pass, have memorized answers on strictly limited topics and are going to use them no matter what the question. But not all erring students can be credited with this conscious cunning, for some irrelevant answers display conscientious and thorough preparation.

Occasionally the explanation lies in the examiner's technique; the question may have been badly worded, the interpretation which seemed obvious to the examiner was not obvious to other readers; thus seemingly irrelevant answers may prove relevant, if the question is re-interpreted.

In other cases the weakness seems to be in the student's reading ability. The student must be technically able to read the question; but the sense of the sentence is not grasped. One word only, or part of the sentence only, dominates the rest and evokes the associations to this one element. This is an example of the so-called global thinking supposedly characteristic of early childhood, where a general concept is present or brought to mind, but finer discriminations cannot be made, and analysis, perception of detail and component parts do not occur. This leads to regression to an earlier stage of behaviour, possibly caused, like other regressions, by a stressful situation. Yet surely the concepts in question have been analysed during preparation for the examination? Surely, too, the student has been trained to attend to the different parts of meaning conveyed by whole sentences?

Does the error occur in grasping the meaning of the question or in attempting to respond to it? If it is the latter, the behaviour may be explained as regression to another primitive type of mental activity, to rote-memory in which the information sought can be reproduced only imbedded in the impressions originally accompanying it. It is difficult to believe that, having reproduced all the data, the student still cannot select from this reproduction all that is relevant.

Yet this the student seems unable to do. It is precisely selection and discussion that are avoided. It seems increasingly probable that this avoidance may be due not to ignorance of what is wanted, not to bluff or sophisticated examination technique, not to failure in reading ability, but to emotional factors of anxiety and fear. The student approaches the examination with the feeling of not knowing enough, or of not knowing the material sufficiently well to remember it all. Acute anxiety is aroused by what seems a request to be judged on only a part of what has been learned.

Yet if the relevant material were selected and discussed, the student's answer should develop fully satisfactory dimensions. The student is invited to display a lesser amount of factual knowledge, provided evidence of thought is added.

It is possible that this avoidance by the student of thinking out a new aspect is not irrational, but the result of learning from experience. Even good examination candidates considering a new aspect of a familiar subject discover that their knowledge is inadequate; items of related knowledge do not always present themselves. The candidate has either been content to accept words without close inquiry into meaning, or has learned the accepted formulæ without considering all their implications.

Even where there is no discovery of ignorance, thought does not always operate smoothly; although we have relevant points to make, they may not all occur to us, or arrange themselves in the appropriate pattern immediately. It could be argued that students should have thought so much about the subject beforehand that their thinking has become flexible and well integrated. It remains possible that the examiner calls for discussion of an unforeseen aspect. Thus the student's resistance, conscious or not, to following a new line of thought in examination circumstances (or elsewhere) might be well founded on past experience of unsuccessful effort. It is so much easier to let thinking follow the usual path indicated by a signal word, or let memory take over from it.

This avoidance is to be deplored. It can be overcome at least partly by good teaching. Students who have had sufficient practice both in thinking about new aspects of their subject and in criticizing irrelevant responses may come to recognize more clearly what is relevant and to feel some confidence in their own ability to think independently. More independent study could also help, since thinking flexibly in a subject and perceiving most of its implications are made more easy by increasing knowledge and work in it.

RESISTANCE OF GONOCOCCUS STRAINS TO PENICILLIN

GONOCOCCUS strains isolated in 1944 were found to be highly sensitive to penicillin. From 1946 onwards, the existence of less sensitive strains were observed. Up to the end of 1955, doses of penicillin, twice to four times as great as those which were effective against the strains isolated in 1944, were enough to stop the development of the less sensitive strains isolated at the Statens Seruminstitut, Copenhagen. Then, from a case of gonorrhoea without complications, four strains were isolated which were found to be only one-twentieth as sensitive as the 1944 strains. This discovery and the fact that the incidence of gonorrhoea remained about the same in spite of penicillin therapy indicated the need for further research. This was carried out during 1957 and 1958 by Alice Reyn and M. W. Bentzon, who made a comparison of several hundred recently isolated gonococcus strains with a hundred strains isolated in 1944 (*World Health Organization Chronicle*, 14; No. 3. March 1960). This showed that, for inhibition, about 25 per cent of the strains sent to the laboratory for diagnosis in 1957 required doses of penicillin twenty times greater than had been needed for most strains originally.

Twenty strains showing reduced sensitivity to penicillin were subcultured for 30–90 days on a medium with no penicillin, without any increase in sensitivity being produced.

Both in 1957 and 1958, some 200 strains were tested for penicillin sensitivity by the tablet method, that is to say, by placing penicillin tablets in the culture medium and measuring the zone of inhibition around them. The zone diameters varied between 20 and 50 mm. In both years, about 39 per cent of the strains showed reduced sensitivity, that is to say, zone diameters of 34 mm. or less. In 1958, however, the number of strains with zone diameters of 44 mm. or more was significantly lower than in 1957, which seems to indicate that the selection (and induction) of the strains with a comparatively reduced penicillin sensitivity continues.

None of the 1957 strains was completely resistant to streptomycin, but two of the 1958 strains (from the same patient) were.

In both the 1957 and 1958 strains a significant positive correlation was observed between sensitivity to penicillin and sensitivity to streptomycin.

From June 1957 onwards, atypical gonococcus strains—most of them sensitive to penicillin—appeared in the cultures. The growth of these strains on the routine media is poor; they require special conditions for culture and are able to ferment glucose only weakly or not at all. Serological examination showed them to be distinguished from normal strains by the frequent presence of anti-complementary antigens. The proportion of atypical strains rose to 40 per cent in January 1958 when the culture and fermentation media were changed. The change of culture medium had yet another effect: the inhibition zones of the atypical strains—and of these alone—were greater on ox-heart broth than on ox-meat broth. This phenomenon has not yet been explained. It is possible that the emergence of atypical strains is related to the mode of action of the penicillin.

GLOBULAR CLUSTERS

ASTRONOMY has always suffered because of the uneven distribution of its personnel and equipment between the northern and southern hemispheres. Especially welcome, therefore, are the growing number of contributions from the Radcliffe Observatory at Pretoria. A series of three contributions by Dr. T. D. Kinman (*Mon. Not. Roy. Astro. Soc*, 119, 157, 538, 559; 1959) represents an important addition to our knowledge of globular clusters. A study of their motions in the Galaxy is of interest because these clusters are prototypes of Baade's Population II and are believed to contain the oldest stars in the Galaxy. Kinman has obtained the radial velocities of thirty southern globular clusters, for sixteen of which no previous determinations of velocities existed; velocities are now available for seventy clusters in all, more than two-thirds of the known clusters in our Galaxy. The effect of the metal/hydrogen ratio on the strengths of the spectral lines of metallic elements in the clusters was studied by Kinman. He found that this ratio varies from 0·1 to less than 0·01 for different clusters. He also found that clusters of the earliest spectral type, the stars of which have a very low abundance of metal, form an extended spherical distribution with little concentration in the galactic plane, while those of latest type, the stars of which have the highest abundance of metal, show a strong concentration in the galactic plane. Clusters of intermediate type show an intermediate distribution.

The motion of the Sun relative to the globular clusters was determined; the apex of the solar motion does not deviate from the direction of the Sun's galactic rotation. The new analysis confirms the older conclusion that the orbits of the individual clusters in the Galaxy are highly eccentric. The mean angular momentum per unit mass of the cluster system is the same as the mean for the rest of the Galaxy. This is in accord with the hypothesis that the clusters were formed in a spherical gas cloud which was in the process of contracting to form the galactic disk.

SOME BOTTOM CORES FROM THE SWEDISH DEEP-SEA EXPEDITION, 1947–48

THE final publication of the analyses and conclusions to be drawn from the world-wide collection of cores made by the Swedish Deep-Sea Expedition during 1947–48 is still to come. However, with the enormous amount of material collected and the wide scope of the examinations, it is inevitable that the results of particular studies made by many different workers should be published separately and as soon as completed. Thus during the past two years, five fascicules, comprising ten separate papers on sedimentation problems, have been published in the series of the Expedition reports*. Some of these papers represent exhaustive studies of particular cores, whereas others merely present briefly the results of the application of one particular technique to some core material. The cores from the different oceans of the world crossed by the *Albatross* during the Expedition are dealt with in separate volumes in the reports, all papers relevant to these cores being published in one volume, consisting of several fascicules published as the results become available.

Fasc. 4 of the volume on West Pacific cores contains four papers describing a core of 4 m. taken from a depth of 7,710 m. in the Mindanao Trough. This consists of a thin layer of sand overlying a thick bed of fine-grained terrestrial mud which in turn overlies a bed deposited by series of turbidity currents, containing graded sand layers. The principal work is described by Fredriksson, who has undertaken mechanical, chemical and petrological analyses of both the fine and coarse fractions of the core. These show that the sedimentary material has been derived mainly from the andesitic to basaltic rocks of the nearby Snellius Ridge. The breaking up process is attributed to tectonic movement and volcanic explosion, the fine material being transported by sea currents and the coarser silts and sands by mud slides followed by turbidity currents.

This conclusion is confirmed by the discovery of shallow water benthonic Foraminifera in the coarse layers in the core (Reyment) and of fragments of calcareous algae known to exist in reef-building corals characteristic of shallow water (Horn af Rantzien).

Two papers by Locher describe five cores taken in the West Equatorial Atlantic basin between the Amazon Estuary and the Mid-Atlantic Ridge. All these cores show sand and silt layers with associated beds of blue mud. Mineralogical and petrographical analyses of the heavy minerals of the cores are described and show that there are significant differences between their mineral assemblages and those of samples taken from the Amazon Estuary. The sand layers, which are rich in Foraminifera, have all the properties of turbidity current deposits and are assumed to be derived from the South American continent.

The work of Norin on a core of 18 m. from the central Tyrrhenian Sea is the most complete description of any of the cores discussed here. The core consists chiefly of a calcareous pelagic clay sparsely intermixed with aerial dust and silt. The clay minerals are shown to have been largely derived from the land mass to the east, although it is suggested that the montmorillonite is authigenic. Intercalated in the column of normal pelagic sediment are many layers of coarser and darker materials. Each of these has been studied in detail and is described with regard to its mechanical and mineralogical composition. The layers can be ascribed to three different modes of deposition, each with its own characteristic composition and formation. Eruptions of nearby volcanoes contribute volcanic glass and pumice, although it has been difficult to correlate the layers with known periods of volcanic activity. Some layers with sharp boundaries both below and above are characteristic of exceptionally severe dust storms. Very small quantities of such eolian deposits are found throughout the core. Thirdly, there are the turbidity current deposits which apparently originate on a ridge nearby. The material of these deposits is highly mixed, containing volcanic ash, Foraminifera and quartz. It is thought that the quartz is first deposited on the ridge by eolian transport and later moved by the turbidity currents. A thorough study of the surrounding land geology and of the petrography of the volcanoes in the region enables a very precise study of the origin of the sediments to be made. It is unfortunate, however, that more is not known of the topography of the sea-floor surrounding the core and that more cores are not available to correlate simultaneous deposits.

In the volume on "Special Investigations", the mineral composition of the clay fraction of two cores from the Atlantic and Pacific is compared (Dekeyser and Lippman). From the rather limited data it is concluded that there are marked differences between cores but surprising constancy throughout each core. Brotzen and Dinesen have attempted to correlate the stratigraphic sections of two Pacific cores using a statistical treatment of the foraminiferal assemblages. These appear to be controlled by climatic conditions, and warm and cold periods can be distinguished.

(Goteborg: Elanders Boktryckeri Aktiebolag. 1958 and 1959.)

The correlations, however, are not striking, and there is no evidence that the cores do in fact represent continuous and undisturbed sedimentation.

Perhaps the most interesting general conclusion to be drawn from this series of papers on deep sea sediments is that it is extremely rare to find a core that does represent continuous and undisturbed sedimentation. In every core described, there is evidence of a great deal of horizontal displacement of sediments after their initial deposition, by slumps, mud slides and turbidity currents. As these are processes controlled by gravity, and taking place on the bottom, the local topography is of the utmost importance. Different physiographical regions, as defined by Heezen, will have different types of sediment deposited. Any attempt at correlation between cores must take this into account.

The work that has been carried out on analysis of the cores obtained by the *Albatross* represents, perhaps, one of the most exhaustive studies ever made on deep-sea sediments. Certainly the collection of papers provides a solid mass of accurate data to which other sediment studies can be referred and which will inevitably lead to a better understanding of the processes involved in deep-sea sedimentation.

A. S. LAUGHTON

A RELATION BETWEEN SOLAR RADIO EMISSION AND POLAR CAP ABSORPTION OF COSMIC NOISE[*]

By DR. M. R. KUNDU and PROF. F. T. HADDOCK
The Observatory, University of Michigan, Ann Arbor

IONOSPHERIC absorption of cosmic noise in polar regions (called polar cap absorption) is believed to be caused by ionization of the upper atmosphere by fast protons (in the energy-range of 10–50 MeV.) emitted from the Sun after a big flare[1,2]. Direct balloon observations of protons have confirmed this hypothesis[3,4]. It is further known that, following the associated solar phenomena, the absorption event begins after a highly variable delay of 1–50 hr. The association of some proton events with metre-wave outbursts of continuum radiation has led to the belief that cosmic-ray particles, or fast protons, are accelerated by the same mechanism as the fast electrons responsible for continuum radiation, that is, synchrotron radiation from high-energy electrons accelerated in magnetic fields in the solar atmosphere. The use of polar cap absorption as a detector of low-energy cosmic rays suggests the importance of identifying the nature of solar radio emission which might be associated with these absorption events. In this article, we intend to make a statistical study of the nature of centimetre-wave as well as metre-wave radio outbursts associated with polar cap absorption events and, if possible, to draw general conclusions regarding the prediction of the proton events.

During February 1956–July 1959, 31 events of polar cap absorption have been reported[1,2]. For the radio burst data we have used the single frequency observations of the University of Nagoya on 9,400, 3,750, 2,000 and 1,000 Mc./s., of Ottawa on 2,800 Mc./s., and the dynamic spectrum records of the University of Michigan and the Harvard station at Fort Davis in 100–600 Mc./s. band and of Sydney in 40–240 Mc./s.

Metre-wave outbursts of continuum radiation characterized by its broad-band spectrum, long duration and strong polarization is called type IV radio emission, and it is believed that broad-band centimetre-wave outbursts are also of the same nature. A centimetre-wave outburst is defined as a burst of emission having a peak intensity greater than 100 units (1 unit = 10^{-22} W.m.$^{-2}$(c./s.)$^{-1}$), and we shall define the centimetre-wave outbursts having peak intensities greater than 500 units over the entire wave-length range of 3–30 cm. as intense broad-band centimetre-wave outbursts and those having peak intensities greater than 100 but less than 500 units over the same wave-length range as moderate broad-band centimetre-wave outbursts.

Of the 31 polar cap absorption events so far reported, 28 events occurred during periods of centimetre-wave observations, and in only 18 events were there simultaneous metre-wave spectral observations. All 28 absorption events have been identified as being associated with centimetre-wave outbursts. The solar radio events associated with polar cap absorption events are intense centimetre-wave burst radiations which have a very wide spectrum, extending down to metre-waves. The burst radiation on centimetre/waves is always partially polarized and it usually lasts more than 10 min.; in some cases several hours. Simultaneous dynamic-spectrum observations made in 18 cases on metre-waves show that in the majority of the cases they are associated with type IV radio emission. The details of the association of the polar cap absorption events with the solar radio outbursts are summarized in Table 1.

Table 1. TWENTY-EIGHT POLAR CAP ABSORPTION EVENTS (August 1956–July 1959)

Associated centimetre-wave outbursts	Associated metre-wave outbursts		
	Type IV	Type II (No Type IV)	No spectral observations
28	15	3	10

Table 1 shows that all 28 polar cap absorption events are associated with centimetre-wave outbursts. Their peak intensities are comparable over the whole wave-length range of 3–30 cm.; the spectrum is rather flat in this wave-length range.

---

[*] Since the preparation of this article, a note on the same subject (*Nature*, 185, 89; 1960) by Drs. A. R. Thompson and A. Maxwell came to our notice. These authors discuss the relation of low-energy cosmic rays with type IV metre-wave outbursts of continuum radiation, but do not consider the centimetre-wave outburst radiation which, as discussed in this article, plays a very important part in the occurrence of low-energy cosmic ray events.

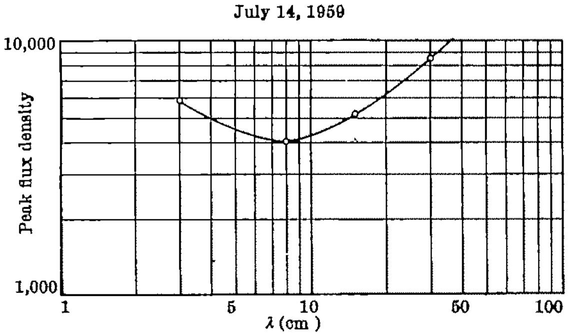

Fig. 1. Peak intensity ($\times 10^{-22}$ W.m.$^{-2}$ (c./s.)$^{-1}$) as a function of wave-length (cm.) during a broad-band centimetre-wave outburst associated with a polar cap absorption event

The spectrum of a typical outburst associated with an absorption event is shown in Fig. 1.

As shown in Table 1, nearly all the centimetre outbursts have type IV metre-wave emission associated with them. There are three cases in which the metre-wave event consists only of a group of type III bursts and a type II outburst without the appearance of a type IV event. Since there are reasons[5] for believing that centimetre-wave outbursts are emissions of type IV and that the type IV emission spectrum can sometimes have an abrupt low-frequency cut-off, one can assume that these three events are also type IV emission with peak intensity in the centimetre range.

As we have mentioned above, the polar cap absorption event follows the associated solar radio event with a delay varying from 1 to 50 hr. If we divide the centimetre outbursts according to their intensity into two classes, intense and moderate, we find that the average delay does not exceed 5 hr. for events associated with intense centimetre outbursts. For the moderate outbursts, the delay is greater. This result is summarized in Table 2.

Table 2 shows that the polar cap absorption event has a strong tendency to occur within 5 hr. of an intense centimetre-wave outburst. Statistically, the greater the intensity of the centimetre-wave outburst, the shorter the delay of the onset of the absorption event.

Table 2. CENTIMETRE-WAVE EVENTS ASSOCIATED WITH POLAR CAP ABSORPTION EVENTS

Centimetre-wave intensity class	Number of centimetre-wave outbursts	Number of associated metre-wave outbursts			Delay of polar cap absorption events	
		Type IV	Type II (No Type IV)	No spectral observations	< 5h	> 5h
Intense	16	10	2	4	13	3
Moderate	12	5	1	6	3	9

Thus, one can conclude that the polar cap absorption events are very closely associated with metre-wave continuum outbursts of type IV as well as broad-band centimetre-wave outbursts which are believed to be of the same nature as type IV emission on metre-waves. However, it is rather difficult to determine if all centimetre-wave outbursts will be associated with polar cap absorption events, since observations of polar cap absorption were not continuous until May 1958. Moreover, centimetre-wave dynamic-spectral observations will probably be necessary to determine if a particular centimetre outburst is the type associated with a polar cap absorption event and such observations have only just begun[5]. However, continuous observations of polar cap absorption since May 1958 are available, and some knowledge of the spectra of centimetre-wave outbursts can be obtained from single frequency measurements in the wave-length range of 3–30 cm.

We have analysed the centimetre-wave outbursts observed during the period May 1958–July 1959 in an attempt to determine the characteristics of centimetre-wave outbursts which are most likely to be associated with the polar cap absorption events. From our knowledge of the polar cap absorption events and the characteristics of the centimetre-wave outbursts associated with them, we have made a pre-selection of the outbursts used in our analysis. Thus, we have selected only the outbursts having a rather flat spectrum in the wave-length range of 3–30 cm. with peak intensities greater than 100 units over the entire range, and the duration of which is greater than 10 min. We have selected 34 such centimetre-wave outbursts. The association of these outbursts with the polar cap absorption events is shown in Table 3. Also shown in the same Table is the association between type IV metre-wave outbursts and the polar cap absorption events. It should be noted that metre-wave dynamic spectral observations were not available in all cases, and therefore we have used the single frequency observations on 200 Mc./s. to identify type IV emission in five cases.

Table 3 shows: (1) Only about one-third (35 per cent) of all centimetre-wave outbursts having peak intensities greater than 100 units over the wave-length range of 3–30 cm. are associated with polar cap absorption events. (2) About 83 per cent of intense broad-band centimetre-wave outbursts are associated with polar cap absorption events. (3) About 53 per cent of all type IV metre-wave outbursts are associated with polar cap absorption events.

Table 3. ASSOCIATION OF RADIO OUTBURSTS WITH POLAR CAP ABSORPTION EVENTS (May 1958–July 1959)

Radio outbursts	Centimetre-wave intensity	No. of radio events	Polar cap absorption events		Percentage of polar cap absorption association
			Yes	No	
Broad-band centimetre-wave outbursts independent of metre-wave outbursts occurrence	intense and moderate	34	12	22	35
	intense only	12	10	2	83
Type IV metre-wave outbursts independent of centimetre-wave outbursts occurrence		19	10	9	53
Type IV metre-wave outbursts associated with broad-band centimetre-wave outbursts	moderate	7	0	7	0
	intense	12	10	2	83

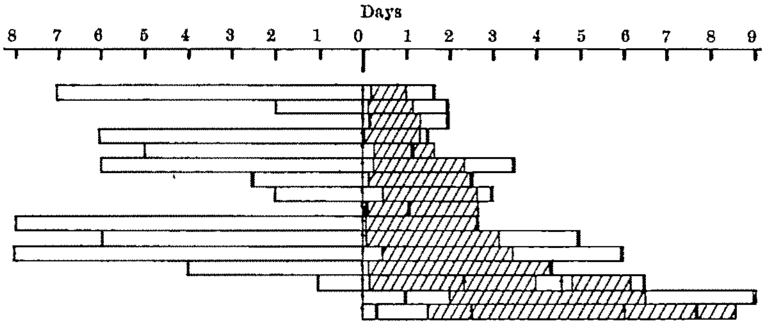

Fig. 2. Vertical arrow indicates the onset of broad-band centimetre-wave outburst or type IV event, double vertical lines indicate the appearance (left) and disappearance (right) of an active region of noise storms and hatched portions correspond, from top to bottom, to polar cap absorption events starting on Sept. 12, 1957; July 24, 1957, Sept. 26, 1957; July 29, 1958; Feb. 10, 1958; Sept. 21, 1957; July 14, 1959; Jan. 20, 1957; Sept. 22, 1958; Aug. 16, 1958; July 3, 1957; June 22, 1957; May 11, 1959; Aug. 29–Sept. 2, 1957; Mar. 25, 1958; Aug. 21–26, 1958

These outbursts are also associated with broad-band centimetre-wave outbursts, and therefore the association of the latter with polar cap absorption events increases from 35 to 53 per cent when type IV emission is associated with them. (4) Type IV metre-wave outbursts associated with moderate centimetre-wave outbursts are not associated with polar cap absorption events. (5) About 83 per cent of the type IV metre-wave outbursts associated with intense centimetre-wave outbursts are also associated with polar cap absorption events.

Thus, it follows that the intense broad-band centimetre-wave outbursts which are frequently associated with type IV metre-wave outbursts are the type of solar radio events most likely to be associated with polar cap absorption events. The occurrence of type IV outbursts on metre-waves alone is not a sufficient indication for the occurrence of polar cap absorption, but it must be simultaneous with intense centimetre-wave outbursts observed over the whole wave-length range of 3–30 cm. This result can be used in the prediction of the solar proton events. It should be noted, however, that the foregoing result is based upon limited results covering only 15 months, during which continuous observations of polar cap absorption were available.

It is known that broad-band centimetre-wave outbursts and type IV metre-wave outbursts of continuum radiation following solar flares do not last more than several hours, but the associated polar cap absorption can last several days. Also, balloon observations have detected the presence of protons up to several days after the associated solar event. The time-scale of the proton-induced polar cap absorption event is comparable to the duration of radio noise storms originating in active regions on the solar disk. We know that such noise storms occur only on metre waves and longer. A convenient source of daily records of radio-noise storms is given by the Nançay 169-Mc./s. interferometer observations which are displayed as 'active regions' on a diagram showing one-dimensional evolution of these regions[6]. On analysis, it is found that of the 27 polar cap absorption events, during which there were simultaneous interferometric observations, only seven (about 25 per cent) occurred during periods free of noise storms on 169 Mc./s. The remaining 20 events occurred during periods of enhanced 169-Mc./s. radiation. A graphical representation of the sequence of events—the 'active regions' of noise storms, the polar cap absorption events and the onset of broad-band centimetre-wave outbursts or type IV event—is shown in Fig. 2.

It is seen that the duration of the polar cap absorption event appears to be related to the presence of noise storm regions. The absorption starts after broad-band centimetre-wave outbursts or type IV event and continues approximately so long as the 'active region' is present. Further, there exists a close correlation between the presence on the Sun of the sources (determined by optically associated flares) where broad-band centimetre-wave outbursts or type IV events occur and the 'active regions' of noise storms[7].

The relation of the duration of the polar cap absorption events with the presence on the Sun of the 'active regions' of noise storms on 169 Mc./s. is more clearly seen from the two correlation diagrams shown in Fig. 3. In these diagrams, the duration of the polar

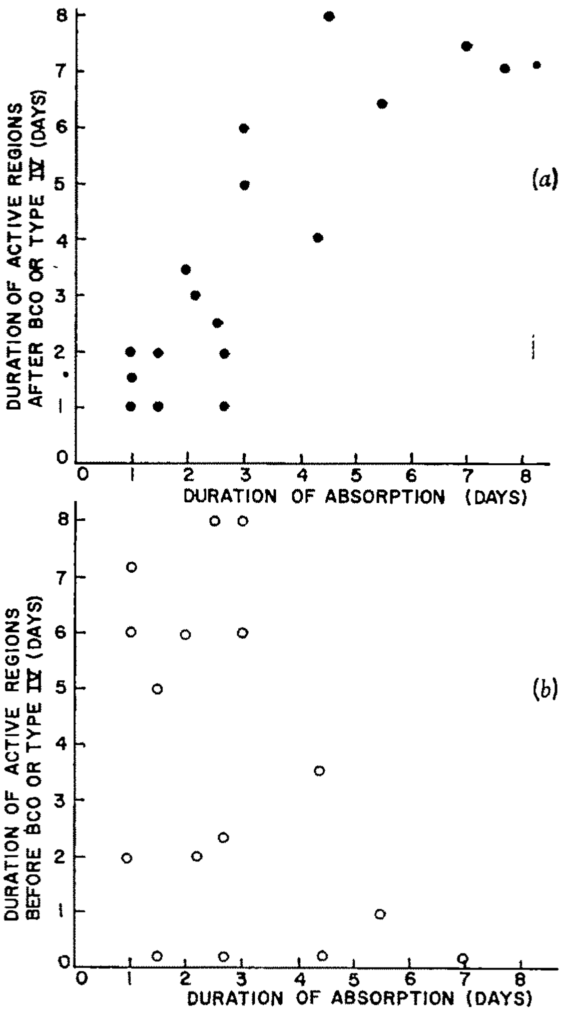

Fig. 3. Duration of active regions of noise storms (a) after and (b) before the onset of broad-band centimetre-wave outburst or type IV event, plotted against the duration of polar cap absorption

cap absorption event is plotted against the duration of the 'active regions' of noise storms (*a*) after the occurrence of the broad-band centimetre-wave outbursts or type IV event (Fig. 3*a*), and (*b*) before the occurrence of the broad-band centimetre-wave outbursts or type IV event (Fig. 3*b*). Where more than one type IV event occurs during the presence on the Sun of the 'active regions', the total duration of all the polar cap absorption events is considered. It is evident from these two diagrams that the occurrence of a broad-band centimetre-wave outburst or type IV event is an important indication for the occurrence of a polar cap absorption event the duration of which appears to be related to the duration of the 'active regions' of noise storms after the broad-band centimetre-wave outburst or type IV event, but seems to have no relation at all to the presence of the 'active regions' before the onset of the broad-band centimetre-wave outburst or type IV event.

From the foregoing considerations it appears that the polar cap absorption events are very closely associated with the occurrence of broad-band centimetre-wave outbursts or type IV events and their duration is related to the presence on the Sun of 'active regions' of noise storms.

Thus, our results are consistent with the hypothesis that the cosmic ray particles, or fast protons, are accelerated by the same process as the fast electrons responsible for the emission of broad-band centimetre-wave outbursts or type IV continuum radiation. The presence of magnetic fields over the source of type IV emission, as evidenced by the strong polarization of the radio bursts, suggests the possibility of trapping of high-energy charged particles. The exact mechanism by which the protons accelerated during broad-band centimetre-wave outbursts or type IV emission are retained or generated in the solar atmosphere and gradually diffuse out of the Sun, with the gradual dissipation of magnetic fields, is not known. However, the fact that there is a close correlation between the presence on the Sun of the sources of broad-band centimetre-wave outbursts or type IV events, and of the 'active regions' of noise storms, on one hand, and between the duration of the polar cap absorption event and the duration of 'active regions' following the broad-band centimetre-wave outbursts or type IV events, on the other, suggest that these 'active regions' might play some part in the storage (or trapping) of the protons responsible for absorption events in the polar regions.

Thanks are due to Mr. H. Leinbach of the Geophysical Institute of University of Alaska and Dr. D. K. Bailey of the National Bureau of Standards, Boulder, for supplying us with polar cap absorption data before publication. The work described here was financially supported by the Office of Naval Research Contract Nonr. 1224(16).

SCINTILLATION COUNTING OF CARBON-14

By DAVID S. JENKINSON

Rothamsted Experimental Station, Harpenden

A PRECISE method for the radioassay of carbon-14 in aqueous solution was developed for use in work on the decomposition in soil of plant material labelled with carbon-14. This method is suitable for handling large numbers of samples with specific activities of 0·1–10 μc., and does not depend on the chemical form of the carbon or on the colour of the solution. The new method is a development of published methods[1-3] for the radioassay of weak β-emitters by counting the pulses of light emitted by a plastic phosphor in contact with a solution of the isotope.

A cell was made by cementing a disk of plastic phosphor (*N.E.* 102, 0·127 mm. thick, 4·12 cm. diameter, obtained from Nuclear Enterprises, Ltd.), on a disk of 'Perspex' (1·4 mm. thick, 4·12 cm. in diameter) using amyl acetate as solvent. A 'Perspex' ring (internal diameter 3·80 cm., height 2·50 cm., external diameter 4·12 cm.) was then cemented to the phosphor side of the combined disk. The cell fitted the counting chamber of a Panax model *S.C.–L.P.* scintillation counter, being held directly above the photomultiplier tube and in optical contact with it through a film of silicone oil. The radioactive solution was poured into the cell, placed in the counting chamber, and counted using a gain of 14,400, a discriminator voltage of 7·5, and with a voltage of 1,560 on the photomultiplier tube. The cell was then removed, rinsed with distilled water, dried with absorbent paper, and the next sample poured in. When the cell was exposed to strong light the background (32 c.p.m. at 25° C.) increased and returned to normal only after a number of hours. This effect was less marked the thinner the sheet of plastic phosphor; the cell described above could be handled in indirect light without significant rise in background count. An additional advantage in using a thin sheet of plastic phosphor is to decrease the normal background of the cell: a cell constructed with plastic phosphor 1·0 mm. in thickness had a background of 40 c.p.m. at 25° C. The volume of liquid required to cover the floor of the cell completely (4 ml.) covers the plastic phosphor to a depth of 3·5 mm., a depth much greater than the maximum range (0·3 mm.) of carbon-14 β-particles in water. For a given solution of carbon-14 the count rate should therefore be independent of the volume of liquid in the cell, once the floor of the cell had been completely covered. Fig. 1 shows that this was not so. This is because the amount of light reaching the photomultiplier by total internal reflexion at the liquid – air surface varies with depth. This effect was eliminated by adding an opaque dye to absorb all light transmitted through the solution, when the count rate becomes independent of the volume of active solution for volumes greater than 6 ml. (Fig. 1). The count rate is reduced 10–12 per cent by loss of reflected light. Naphthalene leather carbon *G.S.* was a suitable dye for all the neutral and alkaline solutions tested; indian ink was suitable for solutions in which it did not coagulate. The amount of dye is not critical; a concentration of 0·1 per cent was normally used, but varying it from 0·05 to 0·15 per cent did not affect the result. Adding dye to solutions being counted makes it unnecessary to add an exact volume of an active solution to the cell, any volume between 6 and 18 ml. being suitable, and also makes it possible to count coloured solutions, because none of the light reaching the photomultiplier is transmitted through the liquid.

Fig. 2 shows that the count rate is directly proportional to the concentration of carbon-14 in aqueous sodium carbonate solutions, a result also obtained with aqueous solutions of sodium formate labelled with carbon-14. The counting efficiency of the cell depends on the volume of active solution in the cell; for a volume of 6 ml. the efficiency is 0·15 per cent, for a volume of 12 ml., 0·075 per cent. An estimate of the accuracy of the method was made by making two counts (approximately 75,000 each) on a solution of radioactive carbonate, emptying and cleaning the cell, doing another pair of counts on the same solution and repeating the emptying and filling of the cell ten times in all. The standard deviation between cell fillings was 0·5 per cent, within the pairs (statistical counting error) 0·4 per cent.

For accurate results all solutions counted must be homogeneous; when the active material precipitates or settles out high results are obtained, and the count rate rises with time. If the count rate increases the cell should be washed out, replaced in the counter and the background measured. If the background is then normal, sedimentation has occurred; if it has risen then another phenomenon, probably caused by incomplete quenching in the solution, is involved. This occurred with a few of the neutral solutions and all the acid solutions examined. For example, a 10 per cent sucrose solution containing 0·07 µc. labelled sodium formate/ml. gave a count of 2,101 c.p.m. rising to 2,825 c.p.m. in 10 min. When the sucrose solution was removed and the cell washed and dried the background was 1,138 c.p.m., falling in 40 min. to 340 c.p.m. The effect is completely eliminated by adding alkali; a 10 per cent sucrose solution 0·1 molar with respect to sodium hydroxide containing 0·07 µc. formate/ml. gives a count of 1,478 c.p.m., the cell background being the same before and after counting. In counting solutions the behaviour of which has not been investigated it is best to make the solution 0·1 molar with sodium hydroxide as a routine procedure, because once the background count of the cell rises it takes 48 hr. to return to normal.

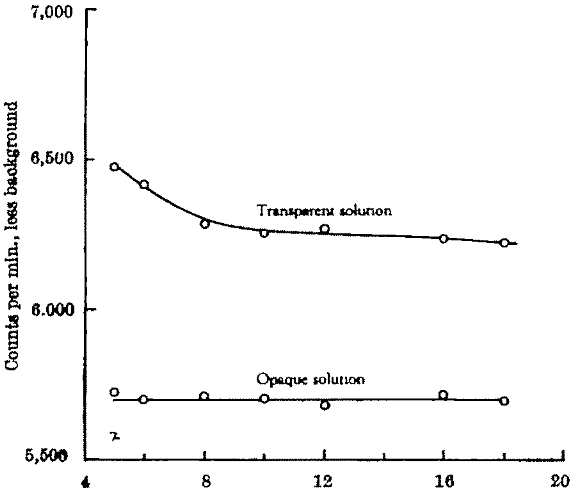

Fig. 1. Relationship between volume of active solution (0·29 µc./ml.) in cell and pulses counted

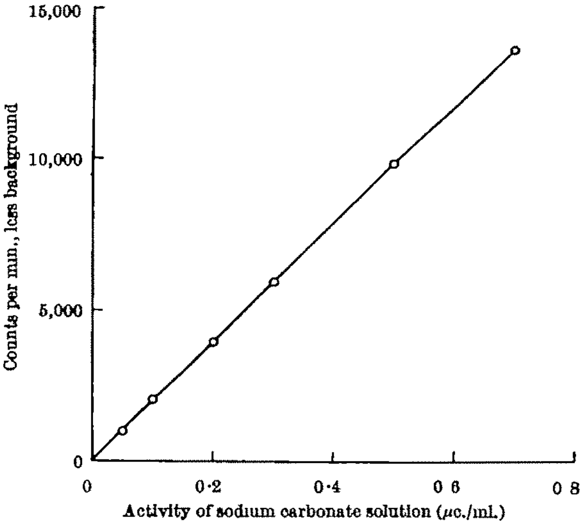

Fig. 2. Relationship between concentration of carbon-14 and pulses counted

The range of β-particles in a liquid is affected by the presence of dissolved organic or inorganic material, particularly at high concentrations, and with materials containing heavy elements. The effect is small with materials containing light atoms; 10 per cent solutions of sucrose, sodium acetate, glycine and sodium hydroxide containing labelled formate or carbonate gave count rates differing by less than 5 per cent from those of aqueous solutions containing labelled sodium formate or carbonate alone. A 0·5 *N* sodium pyrophosphate extract of a compost and a 0·5 *N* sodium sulphite extract of the organic matter of a soil both containing labelled formate gave a count rate 4 per cent lower than the formate alone. Larger effects were obtained with solutions containing heavy metals; a 10 per cent solution of phosphotungstic acid made alkaline with sodium hydroxide depressed the count rate of a formate solution by 14 per cent. In accurate work this effect must be taken into account, either by the use of internal standards or by comparing activities in solutions as nearly identical in concentration and type of solute as possible.

The counting efficiency of this method is very low, but provided sufficient activity is available to give a convenient count rate it provides a very rapid and precise method for the radioassay of carbon-14.

I wish to thank Mr. J. H. A. Dunwoody for the statistical examination of some of the data, Dr. O. Talibudeen for helpful advice, and the Dyestuffs Division of Imperial Chemical Industries, Ltd., for the naphthalene leather carbon *G.S.*

DEVELOPMENT OF RESISTANCE IN MICE TO TUMOUR INDUCTION BY S E POLYOMA VIRUS

By SARAH E. STEWART, BERNICE E. EDDY, MARJEAN IRWIN and STEPHANIE LEE

National Cancer Institute and Division of Biologics Standards,
National Institutes of Health, Bethesda, Maryland

HYBRID $(C3Hf/Hen \times AKR)F_1$ mice were highly susceptible to the induction of multiple types of neoplasms when inoculated, as newly born, with polyoma virus carried in tissue culture[1,2]. In more recent work, they were found to be resistant to the oncogenic effects of the virus after sublines had been carried for 3–13 serial passages in tissue cultures of Swiss mouse embryos, whereas Swiss mice retained full susceptibility to the virus. It thus appeared that while the virus had become adapted to the Swiss mouse by passage in Swiss mouse embryo cultures, it had lost its ability to infect the hybrids. This article reports the results of experiments performed to explore this possibility.

Tissue culture. Mouse embryo tissue cultures of Swiss or $C3H$ mice were prepared by the method previously described[2,3]. Polyoma virus was carried in serial passage in Swiss mouse cultures in all experiments with the exception of one series where three sublines of the virus were carried simultaneously in both Swiss and $C3H/Hen$ embryo cultures.

Virus. Nine sublines of virus were used. The origin of five (Nos. 3469, 60, 3919, 3607 and 3791) has been described[1,2]. The others (Nos. 5729, 5881 and 5884) were isolated from Swiss mice with parotid tumours induced by virus, while No. 695 was recovered from a hamster with sarcomas induced by virus. Sublines 5729, 5881, and 5884 were those carried simultaneously in both Swiss and $C3H/Hen$ embryo cultures.

Mice. Some of the $(C3Hf/Hen \times AKR)F_1$ litters were from mice bred in our laboratory. Others were obtained from the Animal Production Center of the National Institutes of Health, Bethesda, Md. The litters of Swiss mice were also from the Animal Production Center. The importance of these different sources of the experimental animals will be shown in this article. All mice were inoculated subcutaneously within 24 hr. of birth with 0·1 ml. of fluids from tissue cultures. The mice were observed for development of gross tumours, and those not developing neoplasms were killed 24 months after inoculation.

Immunological procedures. Mouse sera obtained by cardiac puncture were tested for the presence of neutralizing antibodies by a procedure described earlier[4,5], and by inhibition of virus hæmagglutinin[6]. Milk obtained from nursing mothers was also tested for antibody content by the inhibition of hæmagglutination of washed guinea pig erythrocytes.

To test for the inhibition of hæmagglutinin, twofold dilutions were made from the serum of individual mice ranging from 1/10 to 1/81,920. Each dilution was tested against two hæmagglutinating doses of the virus. Controls for the hæmagglutinating titres of the virus were made with each test. Milk was tested for antibodies by the same method.

Results. Polyoma virus sublines Nos. 3469 and 60 which were passed serially in Swiss mouse embryo cultures had produced tumours in $(C3Hf \times AKR)F_1$ mice inoculated with passage virus through the ninth and eighth passages, respectively[2]. The hybrid mice receiving subline 60 showed a marked drop in susceptibility after the third passage[2]. The decline in response to subline 3469 was not so pronounced, but became obvious by the thirteenth passage under similar conditions. Three other sublines of virus also did not show oncogenic activity for the $(C3Hf \times AKR)F_1$ mice but produced tumours in Swiss mice. These findings are shown in Table 1.

A possible explanation for the loss of oncogenic activity of polyoma virus for the hybrid mice was that the virus had become adapted to the Swiss mice because it was carried in tissue cultures of Swiss mouse embryos. To determine if this had occurred, virus sublines Nos. 5729, 5881 and 5884 were procured and grown simultaneously in both Swiss and $C3H/Hen$ mouse embryo cultures from their first isolation and then tested for oncogenic activity in newly born Swiss and $(C3Hf \times AKR)F_1$ hybrid mice. Table 2 shows that the hybrid mice were relatively resistant to the virus, although it had grown for 3–5 passages in cultures of strain $C3H$ embryos. Such results

show that growth of the virus in cultures of Swiss embryos was not responsible for its inability to infect the hybrids.

Resistance of the hybrid mice to polyoma virus was finally traced to maternal antibodies. Strain *C3H/Hen* female mice which were used as breeders and housed in the same room with mice that had received polyoma virus were found to have antibodies specific for the virus[5]. Their sera administered to newly born Swiss mice 1 hr. before receiving virus produced passive immunity. Tumour induction could also be prevented by mixing serum with virus prior to inoculation. Pooled sera from 12 breeders tested completely inhibited tumour induction in 100 per cent of 24 Swiss mice given sufficient virus to cause tumours in all of 16 mice that did not receive serum.

It was also found that the antibody could be transferred to the offspring by way of mother's milk. Milk taken from nursing strain *C3H* and Swiss mothers that had been exposed to the virus and from those not exposed when tested for antibody content by the method of inhibition of hæmagglutination showed pronounced differences in effectiveness. The results of a test are shown in Table 3. The range of antibody titres of pooled milk from exposed mice was similar to that observed in the sera of mice which had been exposed to virus (Table 4). The milk and sera from mice free of the virus showed a non-specific inhibition of hæmagglutination in titres of 1/40–1/80, while those with specific polyoma virus antibodies had titres of 1/1280–1/81,920. Since calf serum has been found to have a substance inhibitory for polyoma virus[7], cow's milk was also tested for hæmagglutination inhibition, but was found free of antibodies (Table 3).

Hybrid $(C3Hf \times AKR)F_1$ mice from animals bred in an environment free of polyoma virus were susceptible to the virus. Newly born litters of these hybrids injected with virus subline 695, 16th–18th passage in Swiss mouse embryo, developed the same spectrum of neoplasms (with the exception of mesotheliomas; it was previously reported that mesotheliomas were not observed in the hybrid mice) as did control Swiss mice. 83 per cent of 30 hybrid mice and 100 per cent of 27 Swiss mice developed neoplasms.

Polyoma virus has been shown to be highly antigenic. Serum antibodies specific for the virus have been found in the following animals: rabbits inoculated with virus for the purpose of developing immune sera[4]; mice inoculated when newly born which eventually developed neoplasms[5]; mice not injected with the virus but housed in an environment with inoculated animals[5]; suckling hamsters actively immunized with virus-antiserum vaccine[8].

Specific antibodies against polyoma virus have also been stimulated in adult female hamsters with virus treated with formalin. The offspring of such animals when inoculated at less than 1–3 days of age developed fewer neoplasms, and the neoplasms appeared after a longer latent period than in the offspring of non-immunized females[8].

In a colony of mice with latent polyoma virus infection, transfer of maternal antibodies to the offspring by way of milk, as observed in our experiments, could account for any irregularity of results following inoculation of this virus. Maternal antibodies may also explain the lack of spontaneous parotid gland tumours in an infected colony. Antibodies transferred to the offspring could also explain the absence of these neoplasms in the offspring of tumour-bearing females (Stewart, S. E., unpublished work).

It is also conceivable that latent polyoma virus infections may become activated under certain conditions. Radiation has been reported as activating a latent leukæmia virus[10]. It is also possible that other carcinogens, viral or chemical, may produce tumours by the activation of this or other latent oncogenic viruses.

AMINO-ACID COMPOSITION OF PROTEINS FROM SURFACE TISSUE OF THE TONGUE

By DR. C. J. BARNES and DR. L. N. FERGUSON
Chemistry Department, Howard University, Washington, D.C.

THIS investigation is part of a programme[1] to find a set of molecular properties which may serve as a parameter for predicting the tastes of compounds, and to learn the mechanism by which sapid substances stimulate the chemoreceptor taste organ. The fact that the tongue is practically the only taste-sensitive area indicates that there is something unique about its surface tissue. Since enzymes are involved in all biological processes and in view of the fact that optical isomers may have different tastes, thus revealing the stereospecificity of taste chemoreception, it is logical to examine first the protein material of the surface tissue of the tongue. It was thought that a knowledge of the amino-acid composition of the surface proteins might reveal the presence of unique amino-acids, or, if certain amino-acids are present in unusually large amounts, one could possibly get a clue to the type of molecular interaction occurring between the chemoreceptor and the sapid compound. In this study, the amino-acid composition was determined for the total proteins precipitated from the surface tissue of the tip of a human tongue.

Rectangular strips were removed from the outer surface of the tip, edges, and centre area of a human tongue. The underlying muscle and fatty tissue were scraped away, and the tough outer surface consisting of mucous membrane and papillæ was cut into very small pieces, and homogenized with 5 per cent trichloracetic acid in a Potter–Elvehjem-type tissue grinder. It was necessary to grind some of the very resistant tissue in a mortar. After centrifugation, the supernatant liquid was removed by suction. The precipitated protein was washed several times with 95 per cent ethyl alcohol, twice with acetone, centrifuged, and dried in a vacuum desiccator over concentrated sulphuric acid.

A 50-mgm. sample of this proteinic material was weighed and washed into a 50-ml. glass ampoule with constant boiling-point hydrochloric acid. The ampoule was evacuated, sealed, and heated for 24 hr. at 110 ± 2° C. to affect hydrolysis. 0·5 Ml. portions of the hydrolysate were placed in smaller ampoules and each sample dried in an evacuated desiccator over solid sodium hydroxide for 20 hr. The residue in each ampoule was dissolved in 0·5 ml. distilled water, then 0·5 ml. of 0·2 *M* sodium phosphate buffer *p*H 6·5 was added, and the solution was allowed to stand unstoppered for 4 hr. to oxidize any cysteine present to cystine. Then were added 0·06 ml. of freshly prepared 1 *N* hydrochloric acid and 2 ml. of 0·2 *N* sodium citrate buffer *p*H 2·2, containing *BRIJ*-35 and thiodiglycol. The ampoules were sealed and stored in a freezer for subsequent analysis.

'Amberlite *IR*-120' (*CG*-120) type II from the Rohm and Hass Co. was prepared by the Moore and Stein tap water modification[2] of Hamilton's[3] method of fractionating resins. Two fractions were taken for use, a 280-ml./min. fraction and a 580-ml./min. fraction. Columns of 150-cm. and 49-cm. lengths were prepared using 0·9-cm. inner-diameter tubes.

The 50° C. and the 30–50° C. systems of Moore and Stein were used with the long column. The short column was started at 30° and raised to 50° C. after the carnosine peak.

A synthetic mixture of amino-acids was prepared by adding 125 μmoles of the desired amino-acids to a 50-ml. volumetric flask half-filled with water plus 0·5 ml. of concentrated hydrochloric acid. The volume was brought up to 50 ml. and 2- or 3-ml. portions added to small ampoules. The air in each ampoule was replaced by nitrogen before sealing. The vessels were stored in a freezer until analysed. For analysis, 1 ml. of this solution of mixed amino-acids was diluted with 4 ml. of 0·2 *N* sodium citrate buffer *p*H 2·2 containing thioglycol and detergent solution. 2 Ml. of this solution, equivalent to 1 μmole of each amino-acid, was taken for analysis.

The volume at which each amino-acid was eluted, using a fraction collector, was determined from the contour of the resulting chromatograms and by comparison with the chromatograms of Moore and Stein. Then, the fraction number for the various amino-acids was used for determining the amino-acids present in the hydrolysates, and the sums of the absorbances at each peak were used for determining the quantities of each amino-acid present. Because of the small variations in the volumes used for releasing a given amino-acid from the column, the analysis of hydrolysates were checked by applying the chromatographic procedure to a 50-50 mixture of a synthetic sample and a sample from the protein hydrolysate.

Since tryptophan is destroyed during acid hydrolysis, it was determined by the spectrophotometric method of Goodwin and Morton[4].

Several runs were made on the protein material taken from the tip of the tongue. Typical chromatograms are shown in Figs. 1 and 2.

Lysine from the protein hydrolysate sometimes provided an asymmetrical peak. This raised the question as to whether or not ammonia accompanied the release of lysine from the column. Since the lysine peak from a synthetic mixture was also slightly asymmetric, it was concluded that this 'lysine' peak from the hydrolysate does represent lysine with no more than a trace of ammonia or some other contaminant.

In some runs, a rise in the base-line occurred where histidine would have been eluted. Because of the variable nature of the peak, it was not labelled as such. Even if this elusive peak, is histidine it corresponds to no more than 1·4 mgm. of amino-acid per 100 mgm. of dried protein.

Valine	9 0	7·1	7 8	5·1	3 4	5 8
Total	110	114	113	99 9	117	103 7

Occasionally other rises occurred in the base line absorbance. The base lines generally were not stable enough to attribute these fluctuations to amino-acids.

The computed amino-acid compositions of the protein material from the tip and centre areas of the surface tissue of the tongue are given in Table 1. In general, the ranges of values for a given amino-acid were not large, although there are two exceptions. Samples 1*a* and 1*b* represent two different analyses of the same batch of hydrolysate. One analysis was made on the precipitated proteins from the centre (bitter sensitive) area of the tongue. Little significance can be given to this single run, which was incomplete, because its reliability has not been determined through repeated analyses.

In Table 2 are listed amino-acid compositions of some other proteins for comparison. Since our work dealt with the mixture of proteins precipitated by trichloracetic acid, it is unlikely that a resemblance will be found with a single protein. It is observed, however, that the tongue surface proteins, unlike bulk beef tongue, contain no cystine, and are unique with collagen in having significant amounts of hydroxyproline. Tongue-surface proteins differ from collagen in that the former have tryptophan, a much smaller content of proline and glycine, and a higher percentage of lysine.

The work reported here should be carried further by first making a more refined sectioning of the tongue tissue to include only papillæ. Secondly, the tissue proteins should be fractionated and analyses made on homogeneous fractions.

HIGH FREQUENCY OF SPONTANEOUS AND INDUCED SOMATIC SEGREGATION IN *ASPERGILLUS NIDULANS*

By Dr. ETTA KÄFER

Department of Genetics, McGill University, Montreal

THE ascomycete *Aspergillus nidulans* normally carries haploid nuclei in its hyphæ and produces vegetative spores (conidia) each with a single haploid (n) nucleus. Diploid nuclei arise spontaneously with a very low frequency by fusion of nuclei in the hyphæ. Such diploids can easily be selected and seem fairly stable. As a rare event mitotic crossing-over occurs and diploid segregants are produced, which show recombination for markers of a single chromosome arm[1]. This process seems to be analogous to that occurring in *Drosophila*[2]. The relative frequency of the different cross-over types is very constant and their absolute frequency low[3].

Besides mitotic cross-overs a variety of other mitotic segregants have been isolated from diploids. Recent results show that the types and frequencies which are observed depend to a high degree on the methods of selection and isolation. When standard methods of selection are used, two main further types of segregants, stable haploids and 'non-disjunctional' diploids, are isolated with frequencies usually lower than that of mitotic cross-overs. Special less-strongly selective methods, on the other hand, yield a large variety of *unstable* types, some with much higher frequency. These segregants vary in colony appearance, but they all have reduced growth-rate and viability, and are unable to compete with haploid or diploid colonies. Under favourable conditions, for example, when replated at low density, they all produce vigorous, stable sectors with apparently high frequency. The actual frequency of segregation may not be very high; but as soon as a few stable segregants are produced, these grow so much faster that they surround the unstable parental colony and stop its growth. Usually it is possible to harvest conidia from the centre of such colonies, which are still of the original unstable type and on replating show again the same pattern of segregating sectors.

It was found that any one unstable segregant produces either only haploid or only diploid sectors, except in rare cases when among the diploid sectors a fair proportion of haploid ones is found. All diploid sectors which show any recessive markers segregate simultaneously for all the markers on a chromosome, that is they are always of a 'non-disjunctional' type. The same mechanism of irregular segregation of whole chromosomes may therefore be responsible for the production of all unstable presumably aneuploid types as well as their stable haploid or diploid sectors. It would produce all mitotic segregants, except mitotic cross-overs. It is the aim of the present work to test this hypothesis.

Two methods of isolating segregants are used, which yield unstable segregants with high frequency. Preliminary results have been obtained using for analysis a diploid heterozygous for 19 markers on 7 out of 8 chromosome pairs. This diploid is wild type in phenotype with respect to all recessive markers, but if any mutant becomes homozygous or hemizygous the corresponding mutant phenotype is observed.

The first method of isolation is selective: single conidial heads, which show the mutant phenotype for recessive colour markers, are touched with a needle and the conidia sticking to it plated. This method yields many unstable segregants, which all give sectors of haploid type only. The haploid sectors of any one unstable segregant are identical with respect to most markers, but show segregation for the markers of a few chromosome pairs. The unstable segregant appears therefore as an aneuploid of a hyper-haploid type, and it is possible to deduce which chromosomes are monosomic and which disomic. As not all chromosomes were marked, only a minimal estimate of the chromosome number in any one aneuploid was obtained.

Table 1

Ploidy	Diploid	Aneuploid				Haploid
		$n+1$	$n+2$	$n+3$	Total	
Observed numbers	42	40	14	5	59	14
Frequency	37%				51%	12%

Among 115 segregants isolated in this way the frequency of the various ploidy types was as shown in Table 1 (ref. 4).

The second method is unselective and consists simply in plating random samples of conidia from different colonies of the original diploid on to complete medium. The density (conidia per plate) greatly influences the frequency of segregants recovered by this method. In a first set of platings with about 50 conidia per plate, segregant types were obtained with a frequency of 1/150, while in a second set with much lower density as many as 1/40 were observed. Different strains also may vary in the frequency of segregants produced. All colonies showing abnormal phenotype were classified as segregants and analysed by secondary platings. As all of them showed sectoring with high frequency they are assumed to be aneuploids.

The phenotypes of the different aneuploids vary and seem to fall into several types: (*a*) compact colonies; (*b*) colonies with poor conidiation and dark background colour; (*c*) very slow-growing, sometimes spidery thin colonies, which often are completely overgrown by segregating sectors. Among the last type about half of the aneuploids were found to be hyper-haploid often with at least $n + 3$ or $n + 4$ chromosomes. These hyper-haploids, which represent 10–20 per cent of the total number of aneuploids, produce only haploid sectors.

All other aneuploids produced diploid sectors, which in a high proportion were of parental genotype. It seems likely, therefore, that these aneuploids are of a hyper-diploid type. Besides parental diploid sectors, segregant diploid sectors were found in all cases, which were always of a 'non-disjunctional' type. The minimum number of extra chromosomes in these hyper-diploids could be deduced from the number of different 'non-disjunctional' types found among the diploid sectors. Most hyper-diploids seemed to be of the type $2n + 1$ and $2n + 2$. Some of these hyper-diploids also produce large haploid sectors, with much higher frequency than the parental diploid. Each one shows a distinctive pattern of segregation.

These results suggest that frequently in mitosis of diploid *A. nidulans* chromosomes are irregularly distributed, producing two nuclei of the types $2n + x$ and $2n - x$. So far the analysis of hyper-diploids ($2n + x$) suggests that x is usually small (1 or 2). This would explain why segregants 'non-disjunctional' for more than one chromosome have only very rarely been observed. As the $2n - 1$ or $2n - 2$ types which, according to this hypothesis, are produced have not been recovered with certainty, it has to be postulated that these types are often too unbalanced and short-lived to produce conidia, but that they produce by successive accidental loss of individual chromosomes more stable nuclei of smaller chromosome number. Haploids and 'non-disjunctionals' would then all arise as stable end-products of a secondary process of segregation in aneuploids.

If, on the other hand, aneuploids are produced by a chance distribution of chromosomes, x would have all possible values from 1 to 16 (accepting 8 as the haploid chromosome number[5]). As the types $2n + 3$ up to $4n$ have not been isolated, it would have to be assumed that they are either not present in conidia or produce colonies indistinguishable from the parental diploid. As a rare event this process would then produce a triploid and a haploid nucleus as originally postulated by Pontecorvo[1].

A further possible mechanism for production of haploids is genome segregation[6]. The observation of two cases of 'twin spots' makes it necessary to consider this process as an additional possibility. In both cases haploids of two types, complementary for all 16 distinguishable markers, were recovered from a single head. But in one case the number of colonies obtained was very small; in the other, aneuploid types were present in addition to the complementary haploid types. Obviously further information is needed to decide whether genome segregation occurs.

Two new diploids have now been developed with markers on practically all chromosomes of the eight pairs, mostly in repulsion in one diploid, mostly in coupling in the other. It is hoped that they will provide conclusive evidence as to whether one or several types of mitotic segregations are producing haploids in diploid fungus strains.

Some observations on effects of high doses of X-rays on mitotic segregation in another heterozygous diploid have been obtained recently[7]. It was found that at a dose of about 50,000 r. none of the surviving conidia is of the parental type. The few strains with normal growth-rate and phenotype carry recessive lethals and reciprocal translocations which change the pattern of mitotic segregation, but do not increase its frequency. But the majority of survivors grow very slowly and show a high frequency of segregant sectors, often of a haploid type only. Some unstable, fairly well-growing strains, giving diploid sectors comparable to those found in spontaneous hyper-diploid strains, have also been obtained. In all cases the segregation seems to involve whole chromosomes and appears to be the same mechanism as that observed in spontaneous mitotic segregation. But much more detailed analysis using diploids containing many more chromosomes marked on both arms is needed for a conclusive comparison of spontaneous and induced mitotic segregation.

The segregation found in *Aspergillus nidulans* is parallel in most details to that observed in *Penicillium chrysogenum*, where unstable segregants are obtained after treatment with X-rays[8] or nitrogen mustard[9]. Aneuploidy has been rejected as an explanation of the results in *Penicillium*, because only aneuploids of a hyper-haploid type were considered, but it seems that these new results can provide a good explanation of most observed features of the induced 'high-frequency-segregation' described in *Penicillium*. Unfortunately the number of markers used in the *Penicillium* diploids is too small, and the mutagenic treatment too drastic, to permit detailed comparison and really safe conclusions.

ASTRONOMY

Dirac's Cosmology and the Origin of the Solar System

In one of his earlier papers, Dirac[1] concluded that the gravity coefficient, far from being constant, varies inversely with a "universe time parameter". This result was not accepted by the physicists and it was common opinion that a field theory featuring a non-constant gravity coefficient falls outside the limits of the general theory of relativity. However, Dirac's idea was revived recently. Starting from reasonable assumptions, C. Gilbert[2] showed, in 1956, that Dirac's hypothesis is a corollary of the general theory of relativity. He further computed the age of the universe from the present value of the gravity constant and found it to be $4{\cdot}1 \times 10^9$ years, in remarkable coincidence with the age of the Earth of $4{\cdot}2 \times 10^9$ years, as determined by radioactive methods.

I wish to put forward an apparently acceptable hypothesis of the origin of the solar system, based on the results of Dirac and Gilbert.

Let us consider the state when t, the universe time parameter, was quite small, and let us assume that the mass of the solar system was at that time concentrated in the Sun. Because of the relation $f = x/t$, gravity acceleration in the Sun must have been very great, resulting in large-scale pressure-dependent degeneration of matter. Therefore, the radius of the Sun must have been very small and its angular velocity must have been several times as great as at present.

The centrifugal force and gravitational acceleration on the solar equator have, however, steadily decreased. In the case of gravity acceleration, this was due partly to the decrease of $f = x/t$ and partly to the resulting increase of the solar radius. The increase of radius is considered to have been at first a linear function of universe time, so that:

$$g_s = \frac{xM}{t\,(r_0 + \alpha t)^2}$$

M being the mass of the Sun, and g_s the gravitational acceleration on the solar surface.

However, the impulse momentum of a rotating Sun is given by:

$$\omega \Sigma m_i r_i^2 = \lambda = \text{constant}$$

giving for the solar equator a centrifugal force:

$$r\omega^2 = \frac{r\lambda^2}{(\Sigma m_i r_i^2)^2} = \frac{A}{(r_0 + \alpha t)^3}$$

Comparing the gravity acceleration with the centrifugal force, it is apparent that the two terms will vary, when disregarding the coefficient $\frac{1}{(r_0 + \alpha t)^2}$, according to the functions $\frac{A}{r_0 + \alpha t}$ and $\frac{B}{t}$ respectively. The graphs of the two functions are shown in Fig. 1. In case $A - \alpha B > 0$, there will be an instant t_1 when the centrifugal force becomes equal to the attraction of gravity on the solar equator, so that part of the solar mass can escape into the universe. The molecular forces could inhibit escape temporarily. Escape took place when the weightless mass formed a planet in consequence of its own gravitational attraction.

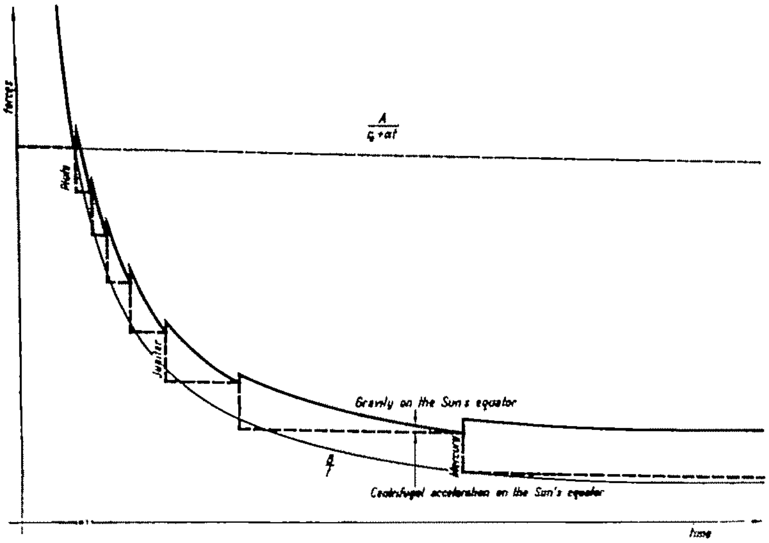

Fig. 1

This escape of mass will result in a decrease of the solar radius and a consequent decrease of centrifugal force on the surface of the remnant Sun. On the other hand, the gravitational acceleration will be greater because of the smaller radius. Therefore the play of forces will be repeated. Fig. 1 shows that after a number of repetitions—at steadily growing time intervals—the centrifugal force will no longer be capable of equalling the force of gravity. (In tracing the diagram the simplifying assumption was made that the discontinuous increase and decrease of the two quantities involved takes place in steps of equal size.)

The escaped masses will, because of the decrease of f, rotate on steadily widening orbits, since fR must be a constant, R being the orbital radius in question.

Therefore, the following equation is valid:

$$\frac{r_n}{t_n} = \frac{R_n}{t}$$

that is:

$$R_n = \frac{r_n t}{t_n} = \frac{r_0 + \alpha t_n}{t_n} . t = \left(\frac{r_0}{t_n} + \alpha\right) t$$

where R_n is the actual orbital radius, r_0 the orbital radius at the moment of formation, that is, at the time t_n.

The graph indicates that the value t_n is—at least within a certain time interval—roughly twice the preceding value, so that:

$$R_n = \left(\frac{r_0}{2^n t_0} + \alpha\right) t = \frac{C}{2^n} + D$$

in agreement with the 'law' of Titius and Bode.

The masses escaping from the Sun will invariably be those of highest specific impulse momentum. Thus it can be understood why the bulk of the impulse momentum of the solar system is borne by the planets.

Gravity differentiation in the Sun must have been most intense at the time when gravitational acceleration was greatest. Therefore, the older, that is, the outer, planets are of smaller bulk density.

The above mechanism can be extended to the satellites of the larger planets, too. The coincidence of the orbital planes is a matter-of-fact corollary and the formation of rings or asteroids is also possible.

This theory is obviously far from being complete. I wish merely to show that the results obtained by Dirac and by Gilbert may in themselves be the nucleus of a theory of the origin of the solar system.

The Extragalactic Distance Scale

THE establishment of the scale of distances in the extragalactic universe rests primarily on the determinations of the distances of the nearest galaxies. These distances have been obtained primarily from a comparison of apparent magnitudes of variable stars or of Population II giants with the known absolute magnitudes of such objects measured in our Galaxy.

Arp[1] has obtained colour-magnitude diagrams for four clusters in the Small Magellanic Cloud and has found that these diagrams are different from colour-magnitude diagrams of similar objects in the Galaxy. Using a faint sequence of magnitudes lent to me by Arp, I have obtained colour-magnitude diagrams for six clusters of the Large Magellanic Cloud and have found that the diagrams differ not only from those found in the Galaxy but also from those found by Arp in the Small Magellanic Cloud. Three of those studied by me are globular clusters: *NGC* 1846, *NGC* 1978, and Anonymous 4. Their giant branches have slopes much more gentle than any observed in globular clusters of our Galaxy. Even the giant branch of *NGC* 6356, which Sandage and Wallerstein[2] find to have an unusually gentle slope, is steeper than those in the clusters of the Large Cloud.

NGC 1831 and *NGC* 1818, two of the three other clusters, are similar in appearance to globular clusters, but are much younger, with colour-magnitude diagrams somewhat similar to those of *M* 11[3] and *h* and χ Persei[4], respectively. They differ from open clusters of our Galaxy not only in their much larger numbers of stars but also in the unexpected location of the giants in their colour-magnitude diagrams. The sixth cluster, *NGC* 1844, a small open cluster, shares this latter peculiarity. *NGC* 1844 has a main sequence similar to that of *NGC* 4755[5], but its giant stars are bluer and brighter.

Because the distances to the nearby galaxies are determined from the apparent magnitudes of the giant evolved stars such as the Cepheids, the *RR* Lyrae variables, and the brightest stars of Population II, the evidence presented by the Magellanic Clouds indicates that these distances are not necessarily correct. The characteristics of the giant stars, and their evolutionary paths, appear to differ in different galaxies and we may not safely use their apparent magnitudes as an index of distance until we thoroughly understand these differences.

RADIOPHYSICS

Faraday Effect in the Transmissions from Fast Spinning Satellites

THE interaction of the satellite spin and the Faraday rotation effect in the ionosphere in producing polarization fading in linearly polarized signals from Earth satellites has been discussed for the case when the satellite rotation period is of the same order as the Faraday fading period[1,2]. In this case, determination of the rate of Faraday fading is difficult unless simultaneous fading records on two frequencies can be taken.

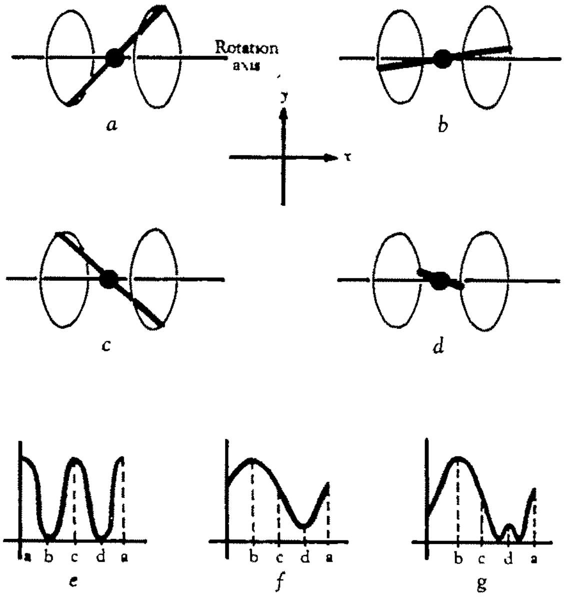

Fig. 1. Four positions of a dipole with its rotation axis and axis of symmetry not coincident. The corresponding signal strength variations for polarizations in the x and y directions are shown at f and e when the line of sight is outside the generated cone, and at g and e when it is inside

The effect of the interaction of satellite spin and Faraday rotation is different for transmissions from a satellite with a rotation period small compared to the Faraday fading period. Consider such a satellite rotating about an axis fixed in space with a transmitting dipole which is not coincident with the rotation axis. As the satellite rotates, the dipole generates a cone, as shown in Fig. 1. Consider the case when the line of propagation is outside this cone. In the absence of Faraday rotation, a receiving aerial with its line of polarization in the x-direction would receive maximum signal strength when the satellite dipole is in the position shown at b and minimum signal strength in the position shown at d. A similar aerial polarized in the y-direction would receive maximum signal strength with the satellite dipole in positions shown at a and c and minimum in positions shown at b and d. These expected signal strength variations over one rotation period are shown in Fig. 1 at e and f. If the line of propagation is inside the generated cone, the variation in the y direction of polarization is somewhat different (Fig. 1g).

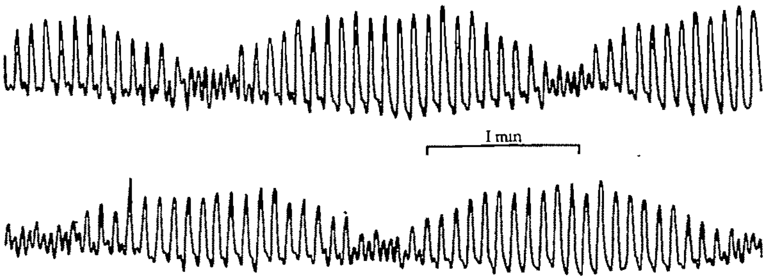

Fig. 2. Variations in the strength of signals from the satellite 1958β2 (*Vanguard I*) received simultaneously on two orthogonally polarized aerials (Feb. 4, 1960)

The effect of 90° of Faraday rotation in the ionosphere would be to interchange the types of variation in the x and y directions of polarization. Changes of a quarter-turn in the amount of Faraday rotation during a satellite passage will thus result in the signal strength variations received on a linearly polarized aerial alternating between types e and f or e and g of Fig. 1.

Records of the 108 Mc./s. signals of 1958β2 (*Vanguard I*) taken on orthogonally polarized aerial arrays show this type of fading (Fig. 2). The rotation period is about 6 sec. and the Faraday fading period is normally greater than 30 sec. The points on the record corresponding to the variation in Fig. 1e are well defined and their times can usually be determined to within ± 3 sec.

Such records taken at the Jodrell Bank Experimental Station over the past nine months are at present being analysed to determine ionospheric electron contents from the observed rates of Faraday fading.

Electron Density Measurements in the Upper Ionosphere using the Faraday Rotation of Radio Signals from Artificial Satellites

Several workers have used the Faraday rotation of radio signals from artificial satellites as a means of investigating the upper ionosphere, and in most cases it has been assumed that the ionosphere is spherically stratified.

Observations made at Cambridge on 1957α2 and 1958δ2 have shown that the variation of the ionosphere with latitude and longitude must be taken into account for satellite passes near or below the peak of the $F2$ layer, if results consistent with vertical incidence soundings are to be obtained. It was found that a sufficiently accurate estimate of this variation could be obtained from hourly ionograms taken at Slough and Inverness.

The effect of the horizontal variation of the ionosphere in a particular case is shown in Fig. 1. On this

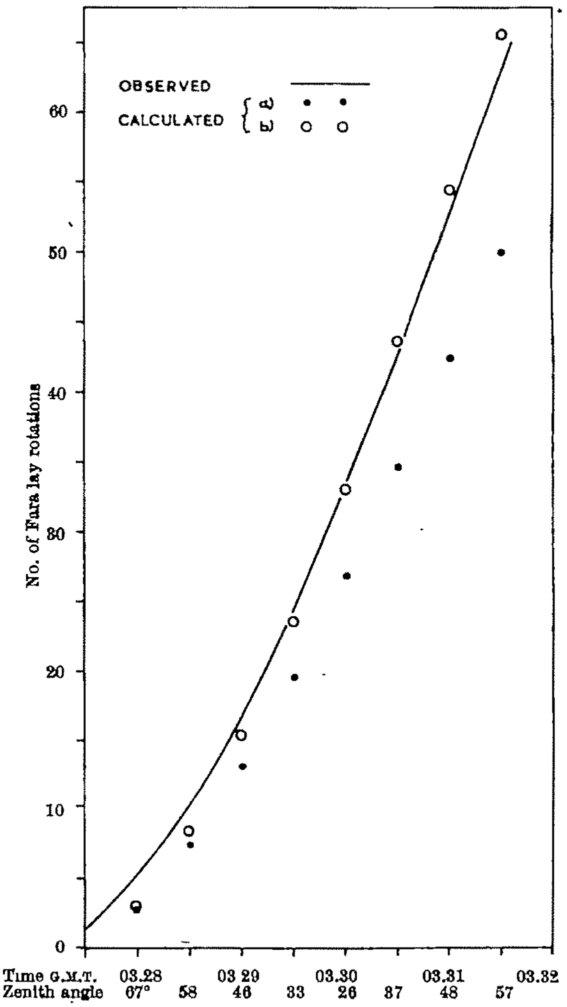

Fig. 1. 20 Mc./s. Faraday rotation, 1957α2/*Sputnik* I, 20/10/57

occasion the satellite was slightly above the $F2$ layer peak at closest approach, so that the profile assumed for the layer above the peak has little effect on the calculated rotation curve.

The points (*a*) were calculated assuming spherical stratification of the ionosphere, using the electron density profile deduced from the Slough ionograms up to the peak, and a semi-parabolic distribution above it. The points (*b*) were calculated from the same electron density profile taking account of the horizontal variation estimated from the Slough and Inverness ionograms. The improved agreement with the observed rotation curve in case (*b*) is quite marked.

Several records of satellite passes well above the $F2$ peak have been analysed, making due allowance for the horizontal variations in the ionosphere as deduced from ionograms, and it has been found that self-consistent results can be obtained from a very simple model of the upper ionosphere. These results are as follow.

Above the $F2$ layer peak the electron density falls off with a scale-height of approximately 230 km., which is of the same order as that found by Bowles[1], and the average ratio of the total electron content above the peak to that below is 3·4 to 1, which agrees well with measurements made by the Moon-echo technique, and measurements using the radio rise and set of artificial satellites by Al'pert *et al.*[2].

Observations made during an ionosphere storm showed a considerable decrease in the total electron content up to the satellite, with little apparent change in the ratio of the contents above and below the peak.

PHYSICS

Growth of Surface Instabilities in a Linear Pinched Discharge

Recent experiments at the Imperial College of Science and Technology, London, have been concerned with the growth of instabilities in a linear pinched discharge in argon. These discharges were produced in a tube 15 cm. in diameter and 50 cm. long at pressures of 0·1–1 mm. mercury and with currents of 40–150 k.amp. The experiments have revealed the presence of surface instabilities of the type shown in Fig. 1, which is typical of many single-shot photographs of the discharge taken through the side of the tube with a Kerr cell camera. The irregularities on the plasma surface first appear when the column is expanding from the first axial bounce, and grow while the plasma is being accelerated towards the axis of the discharge tube between the first and second 'bounces'. In Fig. 2 the diameter of the column, together with the amplitude of the instability, and its mean wave-length, are shown as functions of time for a particular set of initial conditions. In this diagram the diameter of the column has been found by taking the mean of fifty measurements of the local diameter at different points along the tube axis. A numerical estimate of the amount of instability was obtained from the standard deviation of these measurements about their mean.

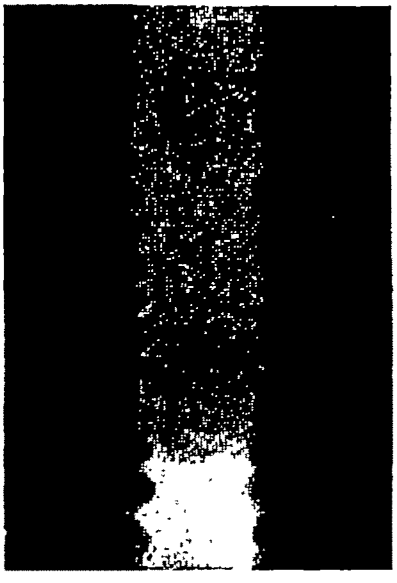

Fig. 1. C, 1,900 μF.; V_c, 5 0 kV.; L, 300 mμH.; p, 330μ. Photograph taken with exposure of 0 4 μsec., 18 μsec. after first pinch

It is suggested that these instabilities are associated with the acceleration of the plasma boundary and are analogous to the Rayleigh–Taylor instabilities[1,2] found when a heavy incompressible fluid is supported against gravity by a lighter one. In the plasma case the magnetic field behaves as the lighter fluid, and the instability grows, as expected, when the plasma is being accelerated by the field.

For plane surfaces the growth should be exponential of the form $\exp(\omega t)$, where the growth-rate ω is given

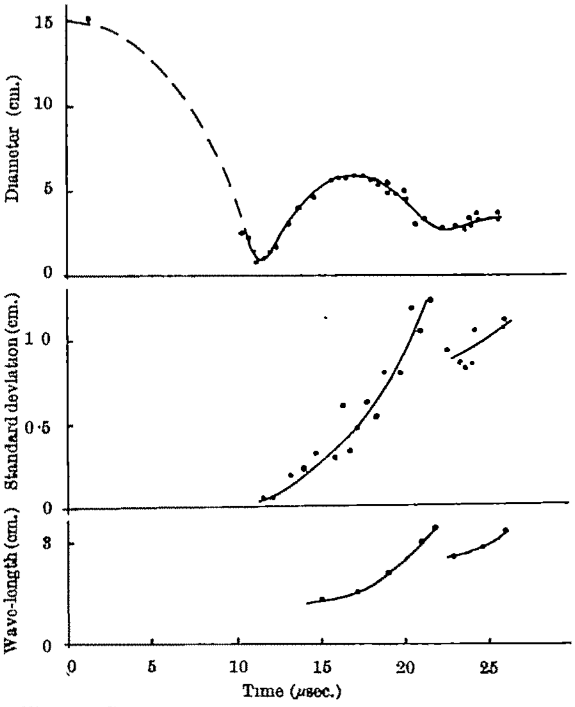

Fig. 2. C, 3,900 μF; V_0, 2·5 kV.; L, 100 mμH.; p, 200μ

by $\omega^2 = gk$, g being the acceleration and k the wave number $(2\pi/\lambda)$ of the disturbance.

Under various initial conditions the measured accelerations and observed wave-lengths allow the growth-rates to be calculated. The values obtained experimentally from the standard deviation curves are about a factor of two smaller than those expected from the above expression. The finite compressibility of the plasma and the cylindrical geometry of the discharge system have not been taken into account and may well influence the numerical comparison.

When dissipative processes such as viscosity[3–5] and resistivity[6], or effects of finite amplitudes[7], are included in the analysis a dominant wave-length should occur. Our experiments suggest that the plasma viscosity is too small to explain the observed wave-lengths.

In the interpretation of the present experiments it has not been found necessary to allow for the growth-rate of $m = 0$ instabilities arising on a steady-state configuration[8–11]. It is suggested that this results from the fact that a likely perturbation will not be axisymmetric in the early stages of growth. In this case the plasma will be either stable or in neutral equilibrium as the increase in B_θ normally associated with a local decrease in r (and vice versa) will not occur.

The shape of the boundary as shown in Fig. 1 is very similar to that observed experimentally[12] for the Rayleigh–Taylor instabilities in fluids, having a rounded convex surface towards the plasma and cusps projecting into the magnetic field.

A detailed account of this work will be published elsewhere.

Use of an Auxiliary Grid to stabilize the Gain of a Photomultiplier

We have recently examined the possibility of reducing the sensitivity of a photomultiplier to changes in supply voltage by means of feedback to an auxiliary grid.

An eleven-stage tube (Electrical and Musical Industries type 6097) was provided with a grid between cathode and first dynode through the co-operation of the manufacturers. The dynodes were connected to one another and to the cathode by the usual resistor chain. Instead of grounding the cathode directly, however, it was connected to Earth through a feedback resistor, normally of the order of some thousands of ohms. An appropriate d.c. bias of the order of a few volts was applied to the grid. A definite fraction of any variation in the extra high-tension supply voltage is thus fed back to the cathode and hence effectively to the grid, with the result that the anode current can be maintained substantially constant.

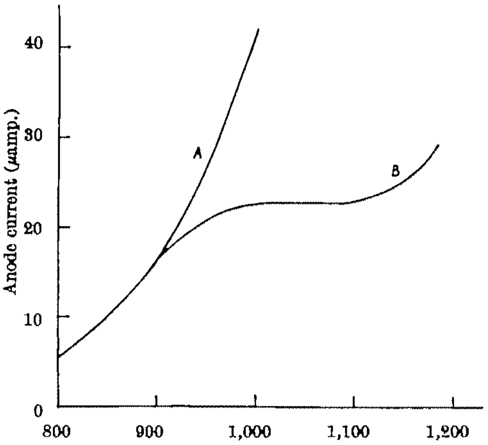

Fig. 1. Direct-current operation

Fig. 1 shows how, under conditions of constant cathode illumination, the anode current of the photomultiplier varies with extra high-tension voltage, *A* when the tube is used conventionally with the grid strapped to the cathode, and *B* with feedback present. It can be seen that quite an appreciable plateau exists. The voltage at which the plateau appears can be shown, both theoretically and experimentally, to be inversely proportional to the value of the feedback resistor. The d.c. bias which must be applied to the grid is found to be effectively constant over a wide range of extra high-tension voltages.

To test the performance of the tube for pulse work it was used as a gamma-ray spectrometer in conjunction with a sodium iodide crystal, low-gain amplifier and single-channel analyser. Curves *C* and *D* of Fig. 2 show how the position of the cæsium-137 photopeak shifts when the extra high-tension voltage is changed from 890 to 980 volts with the tube used conventionally. Curves *E* and *F* were obtained with feedback present and show how the position of the photopeak remains practically unaltered as the extra high-tension voltage is changed from 1,040 to 1,140 volts.

One would expect that the resolution of the peak would worsen with the introduction of feedback,

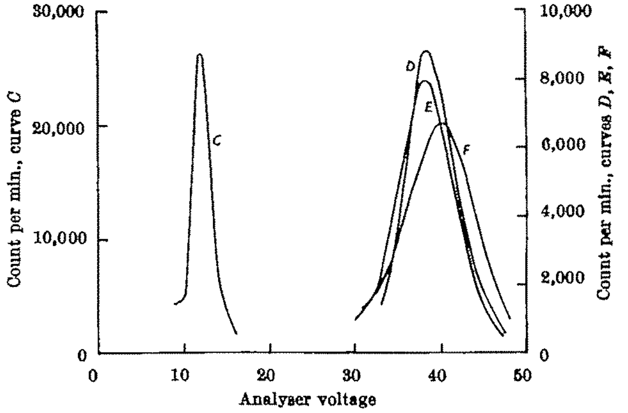

Fig. 2. Pulse operation

since this is equivalent to a reduction of the cathode sensitivity. The value for the cathode sensitivity for the tube used was 26 μamp./lumen, and for this value one would expect under ideal conditions a resolution of about 10 per cent. Due to the fact that neither the tube, crystal nor associated electronics were specially selected for spectrometry, the actual resolution was found to be 17 per cent, when the tube was used conventionally. With feedback the resolution worsened to 20 per cent at one end of the plateau and 24 per cent at the other for the curves of Fig. 2. While this is obviously unsatisfactory, it must be remembered that at the cathode sensitivity of 26 μamp./lumen of the present tube, the resolution worsens very rapidly with decreased cathode sensitivity[1]. With a tube of, say, 100 μamp./lumen sensitivity the resolution varies only slowly with cathode sensitivity, and the introduction of feedback should make little or no difference to it.

In conclusion, it should be remarked that the stability of the feedback resistor chain and to a lesser extent of the bias battery must be of a high order. This, however, is a small price to pay if a relatively simple power supply may be used in place of the ultra-stable supplies at present required for precision work.

It is hoped to publish a fuller account of this work in the near future.

Coherence and Band-width of a Gas Discharge Harmonic Generator

RECENT work has shown that a microwave gas discharge is an efficient harmonic generator[1-3]. These results are of interest since they show promise of producing a reasonable quantity of power in the 1-mm. wave-length region. This would be extremely useful for spectroscopy, especially if the radiation were narrow-band and coherent. Two experiments have been performed to see whether this is so.

Fig. 1 is a diagram of the first experiment, designed to measure coherence. The two harmonic generators were simple neon-filled discharge tubes in wave-guide mounts as previously described[3]. The gas discharge was maintained in both tubes by power from a 2 kW. 3-cm. klystron amplifier, arranged to give pulses of 3-m.sec. duration. By suitable tuning of the discharge tube mounts the fourth harmonic (in the 8-mm. band) was selected. It was passed through low-Q wave-meters to remove other harmonics present. The two 8-mm. band signals were combined in the magic-T and fed to a single crystal detector. By adjusting the 8-mm. wave-guide attenuator and phase shifter a minimum in the output signal could be maintained. This was less than 0·25 mV. across the crystal detector. The corresponding maximum when the two signals were added in phase (by adjusting the phase shifter to give a maximum with the attenuators unaltered) was 50 mV. Hence the coherent signal/noise ratio was at least 100/1.

This cancellation experiment also indicated that the signal was narrow-band since the length of 8-mm. guide before the magic-T made the system dispersive. The second experiment confirmed this. The output from one of the harmonic generators was fed into an 8-mm. superhet receiver. The local oscillator frequency was swept so that the input spectrum could be displayed on a cathode-ray oscillograph. This gave a pulse 1 Mc./s. wide which corresponded closely to the measured intermediate frequency band-width of the receiver. Hence the band-width of the signal was less than 1 Mc./s.

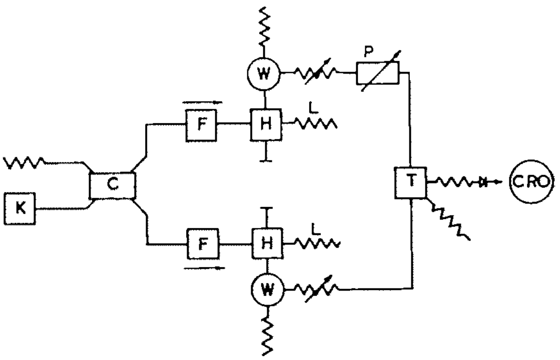

Fig. 1. Block diagram of the experimental apparatus. *K*, 2-kW. X-band klystron; *C*, 3 d.b. directional coupler; *F*, X-band ferrite isolator; *H*, harmonic generator; *L*, X-band water load; *W*, low *Q* wave-meter (*Q*-band); *T*, magic-*T*; *P*, phase shifter

These experiments show that the harmonic generator output is coherent and narrow-band. It is a true line source comparable to a reflex klystron.

We wish to acknowledge the advice and encouragement of Mr. I. M. Ross and Dr. H. Motz during the course of this work. In so far as two of us (N. R. B. and D. W.) are concerned, this work was sponsored in part by U.S. Air Force contract No. *AF* 61 (514)-1183 and for the participation of the third (J. C. V.) this work is published by permission of the Admiralty.

Transistor Modulators for Low-level Direct Current Signals

WE have considered in some detail the problem of using germanium and silicon transistors as choppers in thermocouple-amplifier and other low- and medium-impedance applications. In the past, several circuits have been described using asymmetrical transistors with switching drives which are symmetrical or asymmetrical with respect to the emitter and collector of the transistor. Many of these circuits require careful adjustment and/or selection of transistors to reduce the equivalent input drift with temperature to an acceptable level.

A circuit has been developed in our laboratories, in which a symmetrical transistor is used with a symmetrical drive, giving drift-rates of not greater than 1·5 μV./° C. over a temperature-range of −40° C. to + 100° C. with no adjustment or selection whatsoever.

This has been made possible by the development by Semiconductors, Ltd., of a symmetrical silicon alloy transistor to our specification. This is at present an experimental type, but is available in limited quantities.

It is hoped that it will be possible to publish a full account of this work in due course.

ENGINEERING

A Systematic Method for the Construction of Error-correcting Group Codes

Slepian[1] has pointed out that all systematic binary codes of length n form a sub-group of the group of all binary words of length n. The problem of choosing a systematic code for correcting a given set of errors is thus equivalent to finding a sub-group such that each error to be corrected for lies in separate cosets. Fire[2] has pointed out that the sum modulo 2 of two parity check sequences corresponding to two error patterns is the same as the parity check sequence corresponding to the sum modulo 2 of the same two error patterns. Also, each parity check sequence is uniquely associated with one coset. This sets up an isomorphism between the group of parity check sequences and the quotient group of the code group in the group of all words.

This consideration has led to a systematic method of generating group codes for correcting an arbitrary set of errors. The method has been applied to the generation of maximal two-error correcting codes of length 5–11, which coincides with the groups indicated by Slepian. The method is as follows: (1) Choose a set A of linearly independent error patterns which span the set of all 'allowable' error patterns, that is, error patterns to be corrected. (2) Choose two arbitrary parity check sequences to represent the first two of this set A of error patterns. Let us call this set of sequences B. (3) By modulo-two addition of members of B, generate the set of parity check sequences of all error patterns spanned by B. (4) Write down all parity check sequences so generated as well as the modulo-2 sums of those pairs of parity check sequences at least one of which forms an allowable error pattern by addition-modulo two with the next member of A. (5) Choose a parity check sequence outside the set generated in step (4) to represent the next error pattern in A and append this to the set B. (6) Repeat steps (3), (4) and (5) until all possible error patterns have been spanned.

In the case of the two-error correcting code mentioned earlier, the set A may be conveniently chosen as the set of all single errors, and the initial two parity check sequences can be conveniently chosen as the binary 1 and 2, that is, 000 . . . 01 and 000 . . . 10.

In this case step (4) simply reads: (4), Write down all parity check sequences of double errors generated by the single errors in B as well as the sum modulo 2 of pairs of these parity check sequences at least one of which is a single error parity check sequence. It may be interesting to record that the time taken to generate all two-error correcting codes of 5–11 bits long was 4 hr. by hand.

I am at present setting up a computer programme to generate the parity check sequences for longer blocks of binary digits. After getting the parity check sequences, it is a simple matter to generate the group codes and parity check rules.

I expect to publish the results of the computer data with a more detailed description of the method and its theoretical basis elsewhere.

MINERALOGY

Predehydroxylation State of Kaolinite

The loss of water of constitution from kaolinite with increasing temperature under atmospheric pressure is illustrated in Fig. 1. This loss is very low, up to about 450° C., where it increases very rapidly. The infra-red spectrum of an unheated sample shows a hydroxyl vibration band about equally divided into three transmission minima the frequencies of which are located respectively at 3,700 cm.$^{-1}$, 3,663 cm.$^{-1}$ and 3,627 cm.$^{-1}$.

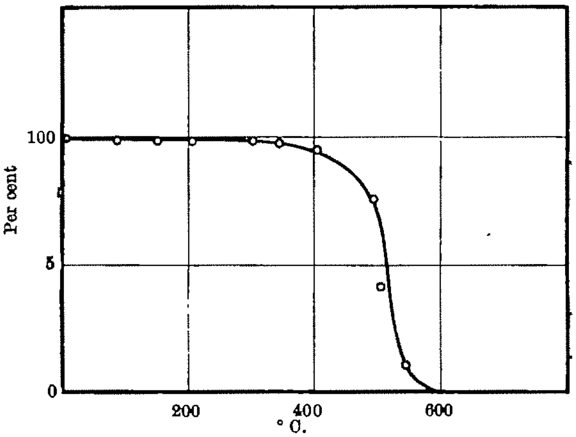

Fig. 1. Relative water content of kaolinite as a function of the temperature under atmospheric pressure

The last one is slightly larger than the other two, the differences being, however, rather small: relative absorbances are 0·91 : 0·92 : 1. When a clay film is heated, the infra-red spectrum undergoes several modifications: the resolution into three components disappears progressively with increasing temperature and, above 400° C., a band only may be observed at about 3,680 cm.$^{-1}$. Beyond this point, relative intensities remain unchanged and, after cooling, the initial shape of the band is restored. Fig. 2 shows the hydroxyl bands observed during a heating and cooling cycle. The process is thus obviously reversible. Fig. 3 gives the changes in frequencies.

One may conclude that, before dehydroxylation starts, kaolinite is modified and brought into a new structural state characterized by the fact that the three initial minima of the hydroxyl vibration band are 'fused' into a single transmission minimum.

As soon as this structural state obtains, dehydroxylation may start, but there is no longer a perfect

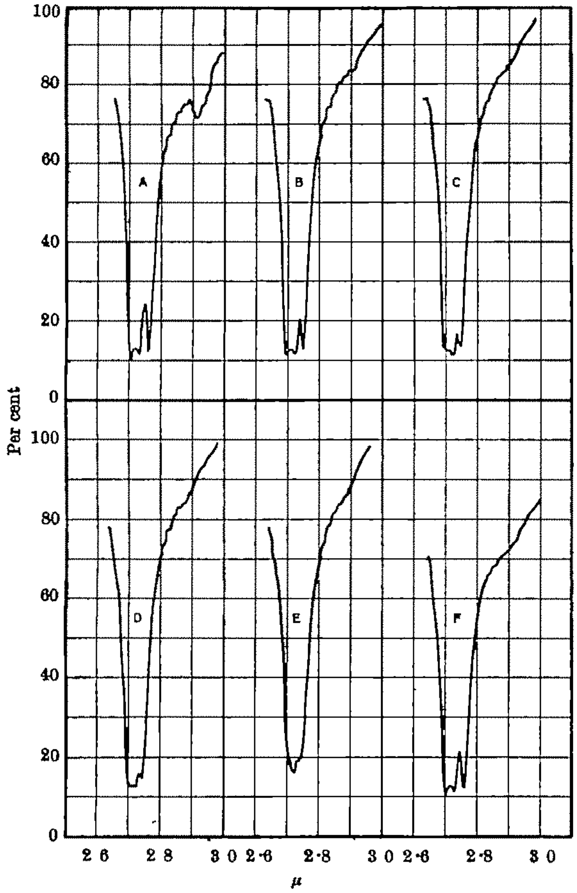

Fig. 2. Hydroxyl bands observed during a heating and cooling cycle before the beginning of dehydroxylation. *A*, 20° C.; *B*, 85° C.; *C*, 210° C.; *D*, 310° C.; *E*, 450° C.; *F*, 20° C.

reversibility of the phenomenon. The absorbance decreases with the water content; the three components of the band reappear when the film is cooled but are shifted about 10–20 cm.$^{-1}$ toward higher frequencies (Fig. 3). In order to represent the progressive mixing of the three components, the height (h) of the barrier between the low- and medium-frequency components, particularly well separated, is given as a function of the temperature as follows:

Temperature	h (in absorbance units)
20° C.	0·295
100° C.	0·175
200° C.	0·095
300° C.	0·040
400° C.	0·02

These values are taken from Fig. 2.

Stubičan[1] has recently studied by infra-red spectroscopy the changes produced in kaolinite by dehydroxylation and has compared the spectra of kaolinite and *meta*kaolinite. He has worked at temperatures which passed the 'predehydroxylation state' here described.

CHEMISTRY

Microquantitative Infra-Red Analysis: Application to Gas Chromatographic Fractions

The need to study infra-red absorption spectra of small quantities of sample has led to the development of new micro-sampling devices and techniques. These have been particularly useful in the qualitative identification of gas chromatographic fractions. Their use has now been extended to quantitative analysis of unresolved chromatographic fractions.

Experimental work was done using Beckman *IR*–4 and *IR*–5 spectrophotometers with beam condensers[1] and a *GC*–2 gas chromatograph. Liquid samples were run in a sealed cell (0·1 mm. thick, 2 μl. vol.) or a very thin demountable cell with grooved windows[2] (0·002 mm. thick, 0 02 μl. vol.), gaseous samples in a miniature folded-path gas cell[3] (60-cm. path, 20-ml. vol.), and solid samples in potassium bromide pellets pressed in aluminium foil[4], in solution, or as melted liquids. The effluent from the chromatograph is condensed on the cooled walls of a tube, concentrated at the bottom of the tube by centrifugation, and transferred to the liquid cells by using a fine capillary tube. Vapours are sampled from the space above the liquid or by passing the effluent directly through the gas cell.

Certain peculiarities of microquantitative techniques have led to measuring procedures which might not be the most desirable in the case of macro-samples. In the transmittance-ratio method for two-component mixtures, the transmittance is measured at two appropriate wave-lengths, and the logarithm of the ratio is plotted against the concentration of one of the components, usually providing a straight line of greater slope than single wave-length measurements. In the absorbance-ratio method, the ratio of the absorbances at two wave-lengths is plotted against the ratio of the concentrations, yielding a straight line provided there is no band overlap. Because the absorbance-ratio method deals with concentration ratios, it does not require close control of cell thickness, solvent concentration, or vapour pressure.

A number of two-component mixtures have been studied using these experimental techniques.

m- and p-Xylene: Spectra of blends of *m*- and *p*-xylene were recorded in the 12–14μ region using the 0·002 mm. cell. Analysis for the *meta* and *para* isomers was based on bands at 13·0 and 12·59μ respectively, using the transmittance-ratio method. A linear calibration plot was obtained. A study of the precision of the method, based on repeated cell fillings with the 1 : 1 mixture, revealed an overall uncertainty in concentration of ± 0·5 per cent and a standard deviation of ± 0·15 per cent. A practical example of the use of this analysis occurs in the gas chromatographic determination of a mixture of benzene, toluene, and *o*-, *m*-, and *p*-xylene. Although it is possible to separate *m*- and *p*-xylene chromatographically, it is not always convenient to establish the necessary conditions. In this case benzene, toluene, *o*-xylene, and combined *m*- and *p*-xylene are determined from the chromatogram, the *meta* and *para* isomers are collected and transferred to the micro-cell, and the relative proportions are then determined spectrophotometrically. The concentrations are found to agree satisfactorily with the true concentrations of the blend (Table 1).

Table 1. TYPICAL COMBINED *GC–IR* ANALYSIS

Component	Known concentration	Determined concentration *GC*	*IR*
Benzene	6·9	7·0	
Toluene	16·0	16·1	
o-Xylene	22·1	21·7	
m-Xylene	36·5	55·2	36·1
p-Xylene	18·5		19·1

To study the effectiveness of the absorbance-ratio method, solutions of the *m*-, *p*-xylene blends in *cyclo*hexane were observed in the 0·1 mm. micro-cell. The plot of concentration ratio versus absorbance ratio yielded a straight line. No attempt was made to control the extent of dilution in solvent beyond ensuring that the xylene peaks were measurable. The effect of variation in dilution was investigated by preparing solutions of the 1 : 1 *meta*-to-*para*-xylene blend in varying amounts of *cyclo*hexane. In the spectra of these solutions the transmittance of the *para*-xylene band varied from 19 to 79 per cent, corresponding to a sevenfold variation in dilution. The measured absorbance ratios were constant to within a small random error amounting to an uncertainty in concentration of ± 0·5 per cent.

Spectra of about 4 μmoles of each of the *m*-, *p*-xylene blends were observed as vapour sampled from above the liquid phase. Because no quantitative control could be exerted over the combined xylenes trapped in this way, the absorbance-ratio method was used. The resulting curve showed considerable deviation from a straight line because of the strong overlap by the rotational branches of the bands, but was nevertheless a useful calibration curve.

Occasionally, it is not practical to perform an analysis in the usual rock-salt region between 2 and 15μ. Because the beam condenser used in the present study has potassium bromide lenses, it can be used at wave-lengths as long as 25μ. *Meta*- and *para*-xylene have bands in this region at 23·13 and 20·7μ, respectively, which can be used for quantitative measurements. Spectral absorption curves were made using cæsium bromide prisms, and satisfactory transmittance-ratio and absorbance-ratio plots were constructed. The uncertainty in the measurements was somewhat greater than in the measurements at 13·0 and 12·59μ because of increased amplifier gain. The noise can be reduced at the expense of longer scanning time.

m- and p-Cresol: This system is another practical case which occurs because of the difficulty encountered in separating *meta*- and *para*-cresol by gas chromatography. A transmittance-ratio plot, based on the *m*- and *p*-cresol bands at 12·88 and 12·23μ respectively, gave a straight line with the same precision as in the case of the xylenes.

2,6-Xylenol and o-Cresol: This mixture is interesting because 2,6-xylenol is solid at room temperature. Blends were studied in a heated micro-cell at a temperature of about 55° C. Measurements were made at the 8·04 and 8·34μ bands of *o*-cresol and 2,6-xylenol respectively and plotted on a transmittance-ratio basis. Departures from linearity found at high concentrations of each component are very likely due to the influence of hydrogen bonding and could be avoided by use of dilute solutions in a non-polar solvent.

Anthracene and Phenanthrene: Solid mixtures of phenanthrene and anthracene were studied by mixing about 100 μgm. of sample with 10 mgm. of potassium bromide and pressing a 1 mm. × 5 mm. pellet. Measurements were made at 11·31 and 12·22μ for anthracene and phenanthrene, respectively. Difficulty in handling these small samples without loss makes the transmittance-ratio method unsuitable. In the case of phenanthrene–anthracene, it is possible to construct a base-line between the wave-lengths of 10·95 and 12·99μ providing a satisfactory basis for absorbance measurements and a straight line calibration curve.

These experiments demonstrate that satisfactory infra-red quantitative analysis can be performed on 20–100 μgm. of sample in liquid, solution, solid, or gas phase.

Portions of this work were discussed at the Rocky Mountain Spectroscopy Conference (August 12, 1958), the American Chemical Society Southwest Regional Meeting (October 25, 1958), and the Pittsburgh Conference on Analytical Chemistry and Applied Spectroscopy (March 6, 1959).

Mechanism of the Oxidation and Reduction of Metal Ions by Hydrogen Atoms

RECENT demonstrations[1-3] that metal hydrides such as CuH^+, AgH^+ and AgH are formed as intermediates in the reduction of metal ions by molecular hydrogen in aqueous solution suggest that similar species may be involved in the oxidation and reduction of metal ions by hydrogen atoms, for example, in the well-known reactions :

$$Fe^{2+} + H + H^+ \rightarrow Fe^{3+} + H_2 \qquad (1)$$

and

$$Fe^{3+} + H \rightarrow Fe^{2+} + H^+ \qquad (2)$$

These and related reactions between hydrogen atoms and metal ions have now been observed in aqueous solutions in which hydrogen atoms were generated in a variety of ways[4-6] or introduced from the gas phase[7,8]; but their mechanisms are still uncertain and the subject of considerable controversy.

For the oxidation of Fe^{2+} (reaction 1) we propose the following mechanism:

$$Fe^{2+} + H \underset{k_{-3}}{\overset{k_3}{\rightleftharpoons}} FeH^{2+} \qquad (3)$$

$$FeH^{2+} + H^+ \underset{k_4}{\rightarrow} Fe^{3+} + H_2 \qquad (4)$$

A detailed kinetic analysis[9] shows this mechanism to be in quantitative accord with the observed[7] dependence of the rate on the Fe^{2+} and H^+ concentrations and yields values of 6×10^4 l. mole^{-1} sec.$^{-1}$ for k_3 and 0·22 for k_{-3}/k_4 at 4°. The mechanism is also consistent with the pH independence, over a wide range, of the relative rates of competing reactions of H with Fe^{2+} and other substrates, for example, oxygen[10] or methanol[11]. It is noteworthy that the oxidation of I^- by hydrogen atoms, where analogous hydride formation is unlikely, proceeds by a different mechanism, namely, electron transfer to H_2^+ (ref. 12). While a similar mechanism has been considered[5,6] for the oxidation of Fe^{2+} its contribution apparently is unimportant because of the slowness of formation of H_2^+ ($k_{H+H^+ \rightarrow H_2^+} = 10^3$ l. mole^{-1} sec.$^{-1}$) (ref. 12) compared to reaction 3. The absence of an efficient acid-promoted isotope exchange reaction[13] is also in accord with this. The two other mechanisms which have been considered previously for the oxidation of Fe^{2+}, namely, the direct termolecular process (reaction 1) and hydrogen abstraction from the hydration shell of the ferrous ion[14,15], also cannot be reconciled readily with all the experimental facts[9].

The proposed oxidation step (4) is analogous to the back-reaction (−5) which is known[1] to occur in the reduction of Cu^{2+} by H_2:

$$Cu^{2+} + H_2 \rightleftharpoons CuH^+ + H^+ \qquad (5)$$

$$CuH^+ + Cu^{2+} \rightarrow 2Cu^+ + H^+ \qquad (6)$$

and which leads to the prediction of a mechanism analogous to that described by (3) and (4) for the oxidation of Cu^+ by hydrogen atoms. It seems likely that oxidation of other metal ions will also occur through this type of mechanism.

Reduction of metal ions by hydrogen atoms may proceed by electron transfer (probably through a bridging anion) or by ligand abstraction[16], for example, the reduction of $FeCl^{2+}$ and $FeOH^{2+}$ the rates of which are 10^2–10^3 higher than that of Fe^{3+} aq.[7,10,17]. The very fast reduction of $Fe(CN)_6^{3-}$ ($k = 10^6$–10^7 l. mole^{-1} sec.$^{-1}$) also is almost certainly by electron transfer[16,19]. In other cases, however, hydride intermediates may be involved. This is particularly likely with metal ions such as Ag^+ or Cu^+ the homogeneous reduction of which by electron transfer (that is, to silver or copper atoms) is unfavourable but which form stable hydride complexes. The observed[3] activation energy of 15 kcal. for the reaction:

$$2Ag^+ + H_2 \rightarrow 2AgH^+ \qquad (7)$$

implies considerable stability for AgH^+ (with respect to dissociation into either $Ag^+ + H$ or $Ag + H^+$)[18] and suggests both that the reaction:

$$Ag^+ + H \rightarrow AgH^+ \qquad (8)$$

will be rapid and that it will occur in preference to electron transfer. It thus seems likely that (8) is the first step in the efficient reduction of Ag^+ by hydrogen atoms followed by dissociation of AgH^+ into H^+ and metallic silver; the latter step is likely to be the slower one and probably involves heterogeneous catalysis. In the reduction of ions such as Fe^{3+} and Cu^{2+} or their complexes there is less reason to believe that initial hydride formation will occur in preference to electron transfer.

Infra-red Spectra of Ammonia adsorbed on Silica–Alumina Catalysts

In an extension of kinetic studies of the catalytic decompositions of hydrocarbons, infra-red spectra of ammonia chemisorbed upon silica–alumina catalysts have been obtained. The techniques employed were similar to those described previously by Eischens *et al.*[1]. A Perkins–Elmer model 112 *C* infra-red spectrometer utilizing calcium fluoride and lithium fluoride optics was modified by mounting the glowbar source in a position above the infra-red cell housing the catalyst deposit held in a horizontal manner.

Thin films of silica–alumina (87 per cent silicon dioxide) were prepared by sedimentation methods: approximately 1 gm. of the 'fluid' catalyst was suspended in 10 ml. of water by vigorously shaking the mixture in a tube and withdrawing the finer particles by means of a small pipette. Sufficient quantities of the suspension of fine particles were placed in a medicine-type throat atomizer and then sprayed on to a calcium fluoride plate oriented vertically over a small hot-plate, namely, with the flat surface perpendicular to the plane of the laboratory desk top. This technique was important in obtaining uniform catalyst films and preventing puddling. Each application of the aqueous suspension to the calcium fluoride plate was allowed to approach dryness before additional spraying commenced. The density of the catalyst deposits was of the order of 2–3 mgm./cm.^{2}. Final pretreatment of the silica–alumina consisted of dehydration at 450–500° C. for 16 hr.

Infra-red spectra of ammonia tenaciously adsorbed upon a catalyst having a surface area of 600 m.^{2}/gm. were observed at room temperature. These spectra exhibit considerable differences from similar investigations reported by Mapes and Eischens[2]. In the current study a series of infra-red absorption bands were resolved in the vicinity of 3,300–3,170 cm.$^{-1}$ attributable to ammonia adsorbed on Lewis acid sites. A second set of absorption frequencies were noted between 3,025 and 2,900 cm.$^{-1}$ ascribable to the reaction products of ammonia and Brønsted sites. From band-widths and band-intensities it was estimated that the concentrations of Lewis to Brønsted sites are in the ratio 3/2, respectively, near room temperature and the ratio increases with rising temperature. A minimum of three discrete energy-levels of Lewis acids and four definite energy-levels of Brønsted sites was detectable. The multitude of infra-red bands exhibited in the stretching region of the spectrum diminished in intensity with decreasing surface coverage in such a manner as to provide further evidence for adsorption sites of differing energies. That is, the ratios of band-intensities changed perceptibly as the ammonia was removed by pumping and elevation of temperature.

The kinetic results of Franklin and Nicholson[3] showed a compensation effect whereby high values of energy of activation corresponded to high values of the frequency factor, and vice versa. The kinetic results could be correlated on the assumption of a logarithmic relationship between the frequency factor and the energy of activation. This observation is suggestive of a distribution of catalytic centres according to their acid strength. The spectroscopic results cited above provide independent confirmation of the distribution of adsorption site energies on the silica–alumina catalyst. The optical spectra suggest that even though the energy distribution may be somewhat continuous in nature, a preponderance of the chemisorption of ammonia occurs upon a small number of spots in an energetic sense.

Addition Compounds between Copper Complexes and Organic Bases

In a recent communication[1], Graddon interpreted the formation of an addition compound between copper complexes such as cupric acetylacetonate and pyridine or other bases as due to formation of a 5 co-ordination complex of the copper atom. This is not the only possible interpretation, nor the most probable one.

The investigations of Lowry *et al.*[2] showed that such bases, together with *p*-cresol, alcohol and probably acetone, can act as catalysts for the mutarotation of beryllium benzoyl camphor and aluminium benzoyl camphor dissolved in carbon tetrachloride or chloroform. In these compounds the metal atoms are showing maximum co-ordination, and the only likely interaction between the catalyst and substrate is by the former replacing one of the points of attachment of the chelate group to the metal atom, the mutarotation becoming possible when the second chelate group (in the beryllium compound) is also detached at one end by thermal energy, amounting to about 20,000 cal./mole. This is supported by the increase in optical rotatory power shown by solutions containing *p*-cresol. It would therefore seem likely that the bases used by Graddon are similarly able to detach part of a chelate group. It is not clear, however, why only one molecule of the base has been found to be attached to a metal atom.

It may further be noted that Graddon used chloroform as solvent in some of his experiments. Lowry *et al.* also showed that beryllium benzoyl camphor forms crystals from chloroform solution containing two molecules of chloroform to each metal atom, and that when these are dissolved in carbon tetrachloride the optical rotatory power differs from those of either the unsolvated material or of the equilibrium mixture: they postulated that it contained equal proportions of the two optically active isomers. It may be interpreted as formed by the replacement of one end of each chelate group by a chloroform molecule, probably attached through a chlorine atom to the metal atom, and also forming a hydrogen bond with the oxygen atom of the detached group. The possibility of similar effects in solutions of copper complexes in chloroform should not be overlooked.

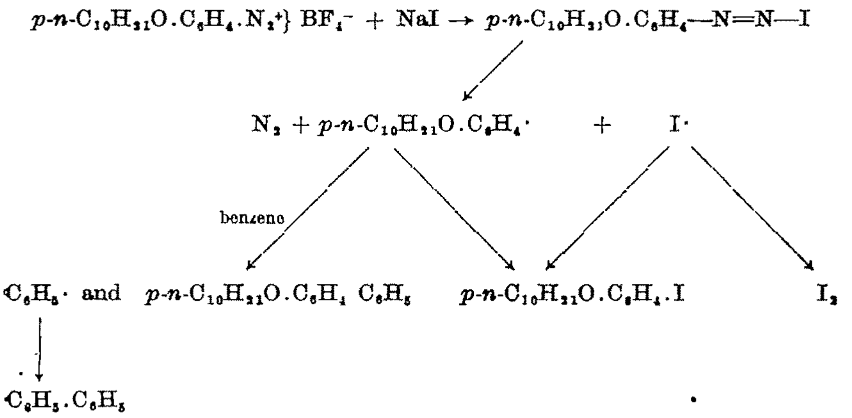
Reaction of *p-n*-Decyloxybenzenediazonium Fluoborate with Sodium Iodide in Benzene

In an earlier communication[1] it was shown that several diazonium salts belonging to the series, $RO.C_6H_4.N_2^+\}X^-$, reacted with β-naphthol in benzene containing an equivalent amount of pyridine to form normal azo-compounds. With Grignard reagents, however, *p-n*-decyloxybenzenediazonium salts gave not only the expected azo compounds but also *p-n*-decyloxydiphenyl and *n*-decyloxybenzene which must have been formed from *n*-decyloxyphenyl radicals produced at an earlier stage. A further instance of the occurrence of radical reactions in the chemistry of diazonium salts has now been found in the reaction of *p-n*-decyloxybenzenediazonium fluoborate in benzene with sodium iodide dissolved in a small volume of dry acetone. Addition of the sodium iodide solution at the room temperature produced a yellow colour followed by the evolution of nitrogen and formation of *p*-iodo-*n*-decyloxybenzene and, in addition, free iodine, an equivalent amount of *p-n*-decyloxydiphenyl, and a trace of diphenyl. The *p-n*-decyloxydiphenyl must have arisen by production of *n*-decyloxyphenyl radicals and their subsequent reaction with the medium. The formation of diphenyl requires the intermediate production of phenyl radicals, presumably by reaction of *n*-decyloxyphenyl radicals with benzene. When the volume of benzene was increased the yield of *p*-iodo-*n*-decyloxybenzene was reduced, but both iodine and *p*-*n*-decyloxydiphenyl were found in increased, and equivalent, amount.

Using *p*-*n*-decyloxybenzenediazonium fluoborate (7·050 gm.) in dry benzene and sodium iodide (3·832 gm.) in dry acetone (25 ml.) the yields obtained were :

Volume of benzene (ml.)	Mol of *p*-iodo-*n*-decyloxybenzene (per cent)	Mol. of *p*-*n*-decyloxydiphenyl (per cent)	Mol. of iodine (per cent)	Total diazonium salt accounted for (per cent)	Total iodine accounted for (per cent)
200	60	14	15	74	75
600	46	26	26	72	72

The following sequence of reactions would explain the results obtained :



p-n-$C_{10}H_{21}O.C_6H_4.N_2^+\}$ BF_4^- + NaI → p-n-$C_{10}H_{21}O.C_6H_4$—N=N—I

Radiation Labelling with Carbon-14 of Aliphatic Hydrocarbons

RADIATION labelling techniques have been successfully developed to introduce tritium atoms in a number of organic molecules[1]. Such a method may also be applied to preparation of carbon-14-labelled compounds, taking advantage of radiation-induced reaction between an organic substance and that containing the radioisotope. Preliminary reports[2] describe the identification of a number of radioactive carboxylic acids in mixtures containing hydrocarbons (or heterocyclic compounds) and carbon-14 dioxide irradiated with X- or beta-rays. Substantially better results, as regards the amount of radioactivity incorporated into the reaction products, have been now attained in the radiation labelling of aliphatic hydrocarbons promoted by high doses of gamma-rays (from spent elements of nuclear fuel) in gaseous systems containing labelled methane as the source of radiocarbon, a saturated hydrocarbon of low molecular weight and an inert gas. Typical experimental conditions were as follows : a mixture of 0·75 m.mole of radioactive methane (specific activity 0·5 mc./m.mole), 0·75 m.mole of propane and 3·0 m.moles of xenon was irradiated in a sealed 'Pyrex' ampoule (125 c.c. approximate capacity). Addition of xenon increased considerably the energy transfer from ionizing radiation to the hydrocarbon mixture, as shown by preliminary runs. The irradiation dose was estimated to be 0·99 × 10^8 rads.

The contents of the vessel were then frozen in liquid nitrogen, the methane pumped away and the residue thoroughly outgassed by the conventional melting-freezing technique. Gas chromatographic methods were employed to separate the radioactive hydrocarbons in the irradiated sample, a mixture of ethylene, propane, butane and *iso*butane, pentane and *iso*pentane, and hexane carriers having been previously added. The gas chromatographic apparatus employed for the analysis was equipped with a conventional thermoconductivity detector, in series with a 100-ml. ionization chamber, connected to a vibrating reed electrometer[3]. Thermoconductivity cell and electrometer responses were registered on synchronized recorders for simultaneous chemical and radiochemical analysis. Satisfactory efficiency in chromatographic separation was attained using two different columns for the analysis of C_2-C_5 and C_6 hydrocarbons : columns containing as stationary phase acetonylacetone on 'Celite *C* 22' and dinonylphthalate on 'Celite *C* 22', respectively 6 m. and 4 m. long, were chosen for analysis of lighter hydrocarbons, with nitrogen as carrier gas, the temperature being 15° C. (Fig. 1). A column of dinonylphthalate on 'Celite *C* 22', at 55° C., was adopted for C_6 compounds.

The radioactivity of each compound was evaluated by integrating the area of the corresponding radiochemical peak. Total radioactivity was determined by two independent methods : (i) calculating the activity corresponding to the sum of the radiochemical peaks ; and (ii) counting known amounts

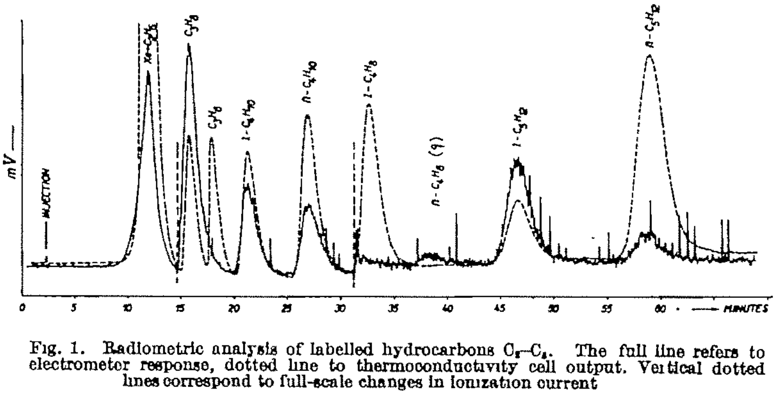

Fig. 1. Radiometric analysis of labelled hydrocarbons C_2–C_5. The full line refers to electrometer response, dotted line to thermoconductivity cell output. Vertical dotted lines correspond to full-scale changes in ionization current

Table 1*

Compound	Activity (μc)†

Unknown§	0·11
i-Pentane	0·51
n-Pentane	0·15
i-Hexane	1·14
n-Hexane	0·49
Total	21·48 μc

* The activity of methane in irradiated mixture was 0·370 mc.

† Radioactivity data were obtained as the mean value of several measurements, the standard deviations being less than 5 per cent.

‡ Radioactive ethylene may be contained in the ethane peak, due to the poor separation in the presence of large excess of xenon.

§ Probably unsaturated linear butenes.

of the radioactive mixture, introduced into a 250-c.c. ionization chamber of the Borkowsky modified type.

The results obtained are summarized in Table 1. It can be seen that a comparatively high percentage of methane radioactivity is contained in the reaction products. Further, the specific activity of the labelled hydrocarbons—except propane—is very high before dilution with carriers. It should also be pointed out, in evaluating the practical interest of the results summarized in Table 1, that the activity of labelled compounds could be substantially increased—in about the ratio 20 : 1—simply by irradiating a mixture containing methane of the maximum available specific activity. Finally, it is worth mentioning that, despite the high dose of gamma-rays absorbed by the gaseous system, only a small amount of the radioactivity was found in unsaturated hydrocarbons.

This work was supported by the Comitato Nazionale Ricerche Nucleari. We also thank Prof. G. Giacomello for valuable suggestions, and Mr. R. Cipollini for some of the chromatographic analysis.

BIOCHEMISTRY

Electrophoretic Components of the Proteins in Honeybee Larval Food

THE proteins of the larval food of the honeybee, *Apis mellifera* L., have been resolved into a number of components by zone electrophoresis[1–3]. The total protein content of larval food (royal jelly) given to female larvæ being reared in queen cells remains fairly constant throughout the feeding period. However, a marked drop in total protein occurs in the food given to worker larvæ midway in the feeding period[4]. It has been observed that larvæ from worker cells can develop into fully mature adult queens if transferred to queen cells (receiving queen larval food or royal jelly) during the first three days of larval life[5]. The purpose of this communication is to note the relation of electrophoretic pattern of larval food proteins to the age and caste of the larvæ receiving the food.

Larval food was gathered from brood cells containing old larvæ (4–6 days of larval life) and young larvæ (less than 3 days) of each caste. Care was taken in obtaining the food samples to avoid contamination from materials clinging to the sides of the cells. The samples were kept at −40° C. until a pool of each caste and age-group was collected. They were obtained during the height of brood rearing from the colonies maintained in the University apiary.

The pools were thawed, stirred, and 1-gm. samples (fresh weight) withdrawn. Each sample was extracted by stirring in 10 ml. of water followed by centrifuging. This was repeated with successive amounts of water until no more protein was found in the supernatant as judged by the biuret test. These were the water extracts. The residue from each sample was then further extracted with alkali (0·5 per cent sodium carbonate) to the same end-point. These were the alkali-soluble extracts. The extracts from each sample and treatment, respectively, were pooled and dialysed against water (changed twice daily) until the dialysate was negative to ninhydrin (about 4 days). The extracts were then pervaporated to 2 ml. volume.

20 μl. of each sample were spotted on Munktell 20*S* paper at a line 14 cm. from the cathode buffer reservoir of an *LKB* model 3276 electrophoresis apparatus. The reservoirs were filled with *M*/10 barbital buffer, *p*H 7·4. Current (4·3 V./cm.) was applied for 18 hr. The sheets were removed, dried with a hair-dryer, and stained with bromphenol-blue[6].

The distribution of water-extracted stained proteins is shown in Fig. 1. There is no qualitative difference apparent between the proteins in the food of young larvæ of queen, worker, and drone castes. Spots 1 and 3, however, are not found in the old worker and drone larval food. A single zone with a migration equivalent to that of spot 3 was present in alkaline extracts of all food samples examined. Thus it is apparent that the qualitative change of the protein constituents of worker and drone larval food is restricted to the water-soluble fractions.

A bluish fluorescent zone not associated with any of the proteins was visible on unstained electro-

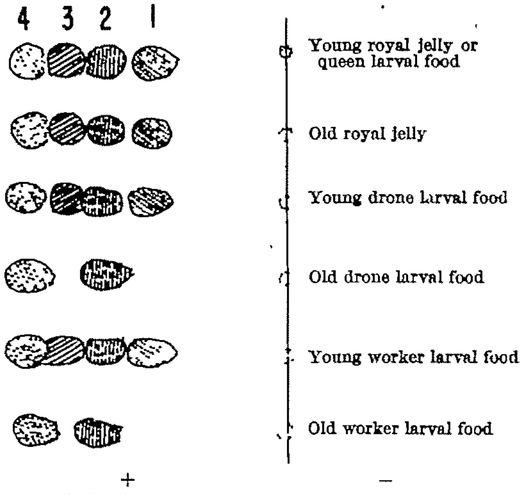

Fig. 1. Electrophoretic patterns (drawn to scale) of proteins from food of honeybee larvæ of different age and caste

phorograms of food of younger worker and drone larvæ and of food of both ages of queen larvæ. The fluorescence may indicate the presence of biopterin[7], which has been associated with queen larval food.

The source of brood-food proteins was sought in adult worker bees: 16 pairs of each of the mandibular, hypopharyngeal and thoracic glands were dissected from (*a*) 6-day post-emergence nurse bees; (*b*) newly emerged bees. The glands were macerated in 0·5 ml. phosphate (M/10, pH 6·0) and electrophorograms prepared as above. The electrophoretic pattern obtained from the hypopharyngeal glands of the 6-day post-emergence adults was similar to that of queen larval food, whereas other glands and glands of newly emerged bees contained a single, immobile spot. The source of young brood-food protein appears to reside in the fully active pharyngeal gland.

Thus the divergence of maturation of the fully fertile queen from that of the infertile worker coincides chronologically with the qualitative change in protein composition of brood-food given to the larvæ of the latter caste. A more concerted study of the changes occurring in the brood-food at this time could help explain the mechanism of this divergence. For example, Ammon and Zock[2] localized cholinesterase activity in their alpha fraction and acid phosphatase in their gamma fraction, corresponding to our spots 2 and 4. It is possible that loss of other biological or nutritional activity is associated with loss, in the older worker larval food, of spots 1 and 3. Such a loss could be related in some way to the subsequent sexually incomplete development of the worker caste.

Desalting of Urine by Electrodialysis

THE electrodialyser previously described[1] has been used for desalting samples of urine prior to chromatography. This apparatus (obtainable from Shandon Scientific Co., Ltd., 6 Cromwell Place, London, S.W.7) was used successfully in the desalting of tissue extracts; but Smith[2], using a modified version of the desalter, reported considerable losses of amino-acids during desalting of urine. It was considered desirable to repeat the experiments in the original apparatus by plotting the 'desalting curve' and submitting samples desalted for varying lengths of time to two-dimensional chromatography.

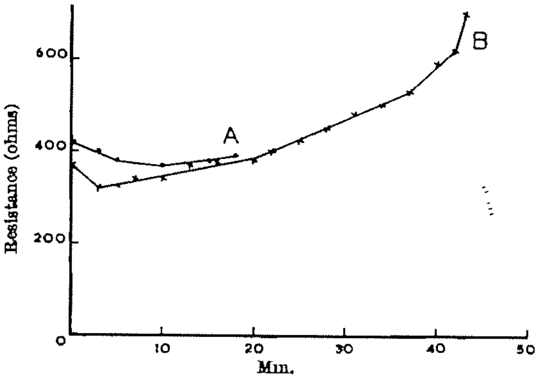

Fig. 1. Ordinates: resistance of the cell. Abscissæ time in min. Runs *A* and *B* are indicated

The urine was part of a 24-hr. sample from a patient at the Royal Alexandra Hospital for Children, Sydney. 10-ml. portions were diluted with 10 ml. of water and placed in the centre compartment of the cell and tap-water was run through the electrode compartments. The current was switched on and the voltages adjusted periodically to maintain the current flowing at 0·200 amp. for the greater part of the run. After 43 min. the resistance of the cell had begun to rise steeply, and the removal of ions was substantially complete (run *B*).

The plot of resistance against time is shown in Fig. 1. Initially, the resistance of the cell falls as salt begins to pass through the membranes; after 20 min. the greater part of the inorganic salts has been removed, and more of the current is being carried by organic ions, as shown by the increase in gradient; finally, the curve rises steeply as the solution becomes exhausted of ions.

Runs *A* (and *C*) were carried out in the same way but were terminated after 18 min. and 10 min. respectively.

The solutions from runs *A*, *B* and *C*, and the original urine were brought to dryness under reduced

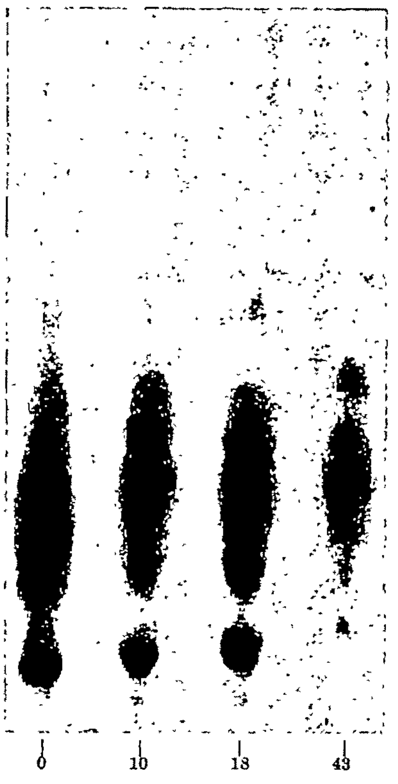

Fig. 2. One-dimensional chromatogram in butanol/acetic acid of the amino-acids in samples of urine withdrawn at zero time and after 10, 18, and 43 min.

pressure and diluted to 2 ml. with 10 per cent v/v *iso*propanol. Equal amounts of each sample were chromatographed in butanol/acetic acid[2] (ascending) followed by phenol/ethanol[2] on Whatman No. 1 paper and developed with ninhydrin. Two-dimensional chromatograms of the urine desalted for 10 min. gave good discrete spots compared with the original urine. A one-dimensional chromatogram of samples withdrawn at various times during the run is shown in Fig. 2.

It is evident from the results that, provided a 'desalting curve' for the urine is plotted, it is possible to stop the run at a time when most of the salt has been removed but little or no amino-acid has been lost. It is also suggested that a procedure of 'total desalting' might be useful in clinical laboratories to measure the total amount of electrolyte in urine, since this is directly proportional to the average current × time.

Biosynthesis of Flavonoids

Several workers have shown that lignin and the '*B* ring' of flavonoids are formed *in vivo* from shikimic acid and certain C_6C_3 compounds. The latter compounds are frequently encountered in plant tissues[1]. The '*A* ring' of flavonoids appears to arise from acetate units[2]. However, the occurrence of the free '*A* ring' or simple derivatives of it have rarely been reported. We have found that on acid treatment kinos yield phloroglucinol, but bark and wood polyphenols do not

Concentrated hydrochloric acid was added to an aqueous ethanolic (1 : 1) solution (5 ml.) of the kino (0·2 gm.), until the strength was 3 *N*. The open test-tube containing the solution was heated in boiling water for 1 hr., and the reaction products examined by two-way chromatography in butanol/acetic acid/water (6 : 1 : 2) and 6 per cent acetic acid. All the kinos examined produced phloroglucinol, which was identified by co-chromatography, its appearance under ultra-violet light while fuming with ammonia (s.g. 0·88) and its colour reaction to diazotized *p*-nitroaniline[3] and vanillin-hydrochloric acid[4].

Phloroglucinol was isolated from *Pterocarpus marsupium* kino (5 gm.) by treating in a similar manner, adding sodium carbonate to the filtered reaction products until the acid strength was about 1 *N*. The resulting liquor was placed on a polyamide column[5] and, after washing with water, the column was developed with ethanol/water (3 : 7) and the phloroglucinol recovered from the appropriate fractions in 0·5 per cent yield. The crystals did not depress the melting point of authentic phloroglucinol and possessed the same infra-red spectrum.

When the kinos were treated with butanol – hydrochloric acid, the anthocyanidins produced by the leucoanthocyanins present were identified chromatographically using Forestal[6] and formic acid – hydrochloric acid – water[7] solvents, and they all contained a phloroglucinol '*A* ring'. In addition, *Eucalyptus* and *Angophora* kinos gave gallic acid, and some kinos gave methyl gallate and protocatechuic acid which were identified by co-chromatography on 2-way chromatograms.

The kinos examined, and the principal anthocyanidins produced with acid, were as follows: *Eucalyptus calophylla* (pelargonidin and cyanidin), *E. camaldulensis* (cyanidin), *E. consideniana* (delphinidin), *E. corymbosa* (cyanidin), *E. elaeophora* (delphinidin), *E. gigantea* (delphinidin), *E. macrorrhyncha* (delphinidin), *E. obliqua* (delphinidin), *E. polycarpa* (cyanidin), *E. radiata* (delphinidin), *E. regnans* (delphinidin), *E. sideroxylon* (pelargonidin, cyanidin, delphinidin), *E. sieberiana* (delphinidin), *Angophora intermedia* (cyanidin), *Pterocarpus marsupium* (cyanidin), *Butea frondosa* (cyanidin).

The material yielding phloroglucinol with acid treatment was insoluble in ether, and formed unresolved streaks on the solvent axes. When solutions of *E. elaeophora* and *P. marsupium* kinos in aqueous ethanol (1 : 1) were made 2 *N* with sodium hydroxide, kept at room temperature for 2–4 hr., then acidified, phloroglucinol was not detected, so that esters of it are absent. Sugars could not be detected in the acid reaction products.

In contrast, extracts of the wood and phloem tissues of several of the above eucalypts which had formed kinos did not yield phloroglucinol on acid treatment. Extracts from the wood of *E. wandoo*, and the barks of *E. astringens* and *Rhizophora mucronata* which are rich in leucoanthocyanins containing a phloroglucinol '*A* ring' also failed to yield phloroglucinol. Thus, kinos contain phenolic components which are absent in the phloem and woody tissues, and consequently kinos appear to be formed *in situ* from other materials. Further evidence[8] indicates that the polyphenols in kinos and in the tissues of trees are formed from carbohydrates which have been translocated or stored as starch.

PHYSIOLOGY

Œstrogen–Insulin Interaction on the Uterus of the Rat

The physiological activity of a specific hormone may be greatly modified by the presence or absence of other hormones, as evidenced, for example, by the Houssay effect[1]; the inhibitory action of adrenal cortical hormones on the response of the rat uterus to œstrogens[2]; the interaction of the various œstrogens on uterine growth[3]; the synergistic effect of growth hormone and thyroxine on body-growth in hypophysectomized animals[4], etc. Of more immediate relevance to the subject to be treated here is the finding that the response of the mouse vagina to œstrogen is heightened by local application of insulin[5]; analogies between the effects of œstrogen and those of insulin on the mitotic activity of mouse ear epidermis have been pointed out by Bullough[6]. Other similarities between the generalized action of insulin and the specific effects of œstrogens on their target organs include an increased potassium uptake by the responding tissue[7–9], and a heightening of glycogenesis and lipogenesis[10–14]. The foregoing observations, together with the fact that except in a few specific preparations œstrogens are ineffective *in vitro*[15], and in large doses produce a transient diabetes[16], suggest a possible interaction between insulin and œstrogen.

The investigations described here were designed to establish whether diabetes and insulin-induced hypoglycæmia would affect the response to œstrogen based on the 6-hr. Astwood assay[17]. This would presumably indicate whether insulin plays a part in the action of œstrogen, and whether the blood glucose is also involved.

Twenty-one- to twenty-two-day old albino rats weighing 40–50 gm. were employed in this study. Diabetes was induced by partial pancreatectomy followed by the subcutaneous injection of 1 c.c. of a 40 per cent glucose solution; 1 hr. after the administration of glucose the animal received 0·5 μgm. of œstrone in 0·1 c.c. of sesame oil subcutaneously; autopsy was performed 6 hr. after the injection. Œstrogen-treated and un-treated non-operated, sham-operated, operated but glucose-uninjected controls were also provided. The extent of the diabetes was determined by the use of the Lilly diabetic test tape; all partially depancreatized glucose-treated animals exhibited at least a ++++ response, that is, a urine sugar content of at least 2 per cent, at autopsy.

Table 1. EFFECTS OF HYPER- AND HYPO-GLYCÆMIA ON THE UTERINE RESPONSE TO ŒSTROGEN

Group	Uterine water (per cent)*	No. of animals
1 Unoperated, untreated controls	81·4 ± 0·2	22
2 Received 0·5 μgm. œstrone	86·8 ± 0·1	12
3 Received 0·5 μgm. œstrone 12 hr. after injection of 2 units of protamine zinc insulin	81·6 ± 0·4	5
4 Received 0·5 μgm. œstrone 12 hr after injection of 2 units of 'Lente' insulin	83·1 ± 0·5	8
5 Received 2 units 'Lente' insulin 18 hr. before autopsy	81·5 ± 0·4	7
6 Received 0·5 μgm. œstrone 2 hr. after partial pancreatectomy	86·0 ± 0·6	7
7 Received 0·5 μgm. œstrone 1 hr. after injection of 1 c.c. of 40 per cent glucose solution	86·8 ± 0·5	9
8 Received 0·5 μgm. œstrone 2 hr. after sham partial pancreatectomy and 1 hr. after injection of 1 c.c. of 40 per cent glucose solution	85·8 ± 0·8	8
9 Received 0·5 μgm. œstrone 2 hr after partial pancreatectomy and 1 hr. after injection of 1 c.c. of 40 per cent glucose solution	81·1 ± 0·6	10
10 Received 0·5 μgm. œstrone 2 hr after partial pancreatectomy and 1 hr. after injection of 1 c.c. of 40 per cent mannose solution	82·4 ± 0·2	6
11 Received 0·5 μgm. œstrone 2 hr. after partial pancreatectomy and 1 hr. after injection of 1 c.c. of 40 per cent fructose solution	81·9 ± 0·3	9
12 Received 0·5 μgm. œstrone 2 hr. after partial pancreatectomy and 1 hr. after injection of 1 c.c. of 40 per cent galactose solution	83·5 ± 0·9	8

* Mean ± standard error of the mean

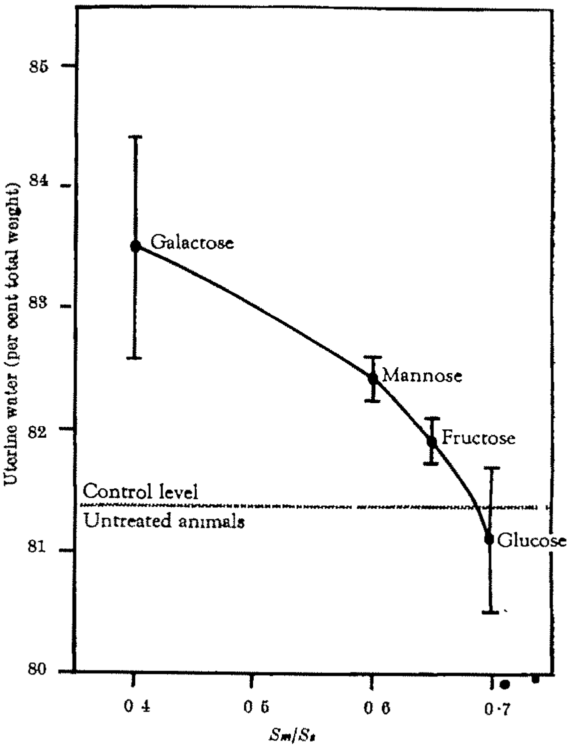

Fig. 1. Relation between S_m/S_s and uterine water uptake in depancreatized diabetic immature rats

None of the other animals in this set of experiments exhibited any evidence of glucosuria.

Hypoglycæmia was induced by injection of insulin 12–14 hr. before the administration of œstrone. Uterine wet weights were determined immediately upon removal of the organ; the tissue was then placed in a pre-weighed aluminium pan and dried at 90° C. for 72 hr.

Additional pancreatectomized groups were provided in which glucose was replaced by fructose, mannose, or galactose; some of the pancreatectomized sugar-treated animals exhibited mild glucosuria.

From the results presented in Table 1 it is evident that the response to œstrogen was dependent upon the physiological integrity of the test animal; the absence as well as the excess of insulin inhibited the action of œstrone. It is difficult to determine whether the inhibition due to lack of insulin was a direct one; diabetic animals exhibit a marked polyuria, and recent studies have indicated that the 6-hr. response to œstrogen is diminished in 'Diamox'-treated animals, which lose a great deal of water[18]. Adrenal involvement in the reduction of the œstrogen response in glucose-treated partially depancreatized animals appears minimal in view of the results obtained with sham-operated glucose-treated controls. It is noteworthy that not all the sugars tested are equally effective in blocking the action of œstrone under identical experimental conditions; Fig. 1 relates the extent of the inhibition to the degree to which normal rat muscle takes up sugar under a given dose of insulin; this parameter was derived from the work of Park *et al.*, who express it as the ratio of the free sugar in the tissue to the sugar concentration in the blood serum $(S_m/S_s)^{19}$. The inverse relation between the extent of œstrogen stimulation and the 'insulin demand' of muscle is highly suggestive.

The fact that insulin-pretreated animals do not respond to œstrogen does not conclusively point to a direct involvement of the blood glucose in the response phenomenon, as the inhibition might be ascribed to increased adrenal secretion in response to the stress of hypoglycæmia. This hypothesis is rather difficult to check in view of the extreme sensitivity of adrenalectomized hyperinsulinized animals.

In view of the results obtained it seems worth while to speculate on the inhibition of œstrogen-induced water uptake observed in the uteri of eviscerated animals. Some reports have explained this phenomenon as resulting from the absence of liver tissue[20]. The results reported here would point to the absence of pancreatic tissue as a prime factor in this inhibition.

Intracellular Potentials in Rat Atria during and after Vagal Stimulation or Acetylcholine Administration

RECENTLY, Vaughan Williams[1] observed that the shortening of the duration of the intracellularly recorded action potential in rabbit atria following vagal stimulation or acetylcholine administration is not always associated with diminished atrial contractions. In fact the association between the two phenomena as observed by Burgen and Terroux[2] might be coincidental. The question arose whether the slowing-up of the atrium which will result from vagal stimulation or acetylcholine administration is always connected with a shortening of the duration of the atrial action potential. The right atrium of adult Wistar rats was impaled with glass microelectrodes filled with 3 *M* potassium chloride, their tip diameter being $< 0\cdot5\mu$ and their resistance 20–35 MΩ. After retrograde insertion of a plastic cannula in the thoracic aorta, the heart and both vagi were perfused *in situ* with normal Tyrode solution. The vagi were stimulated with rectangular current pulses of varying intensity. The pulses had a frequency of 10 c./sec. and a duration of 0·5 m.sec. In a few experiments we succeeded in recording intracellular atrium potentials from artificially ventilated animals that had an intact circulation. The results obtained with perfused rats and with rats with an intact circulation did not differ.

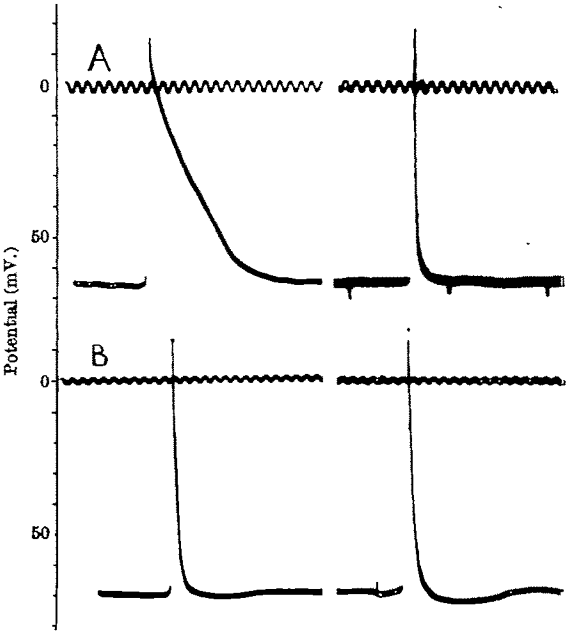

Fig 1. Effect of vagal stimulation and acetylcholine administration on atrial potentials. *A*, left, normal atrial potential; right, atrial potential during vagal stimulation. *B*, left, atrial potential shortly before cardiac arrest as caused by acetylcholine administration; right, potential of driven atrium during acetylcholine administration. Time marks, sine wave of 100 c./s. Stimulus artefacts are visible in right-hand records

During vagal stimulation or during the administration of acetylcholine to the perfusion fluid or to the venous blood the duration of the atrial potential decreased from 100 to about 20 m.sec. The degree of slowing-up of the atrium and the shortening of the atrial action potential were found to be dependent equally upon the intensity of the vagal stimulation and the concentration of acetylcholine in the perfusion fluid or in the blood. Immediately after the arrest of vagal stimulation the heart frequency rose to its original value within 1 sec. In most experiments post-vagal acceleration of heart frequency was observed.

The shortening of the duration of the action potential, however, did not disappear as quickly as the atrial slowing and reached its original value only after 7–15 sec. after the arrest of vagal stimulation. The same observation was made when perfusion with Tyrode solution containing acetylcholine was suddenly replaced by perfusion with normal Tyrode.

In a further series of experiments cardiac arrest was established by perfusing the heart with a Tyrode solution containing 20γ acetylcholine/ml. As an atrium under these conditions will still respond with a contraction to an electrical stimulus[1], the atria were electrically driven up to their original frequency. Despite this frequency of contraction, the duration of the atrial potential remained considerably shortened so long as the acetylcholine administration was continued. On discontinuing the acetylcholine perfusion the duration of the atrial potential gradually rose to its original value.

Consequently we have come to the conclusion that shortening of the duration of the auricular potential during vagal stimulation does not depend upon the rate of the atrial contractions.

We are indebted to the Dutch Organization for Pure Scientific Research for its financial support.

Effect of Methylpentynol on Acetylcholine in the Rat's Brain

Recent observations that methylpentynol, a sedative-hypnotic agent, interferes with transmission in certain cholinergic synapses[1], have led to the demonstration by Marley and Paton that this action is due in part to a reduction in the output of acetylcholine, at least from the superior cervical ganglion of the cat[2]. In the course of work in this and other laboratories on the influence of a number of appropriate neuro-pharmacological agents on the acetylcholine content of the rat's brain, it became apparent that the administration of depressants of the central nervous system in general is followed by a rise in brain acetylcholine (unpublished work and ref. 3). It seemed essential, therefore, for us to include methylpentynol in our survey, because this central-depressant might, in the light of the findings of Marley and Paton, depress the output of acetylcholine by the brain, possibly leading to a depression of the total level of acetylcholine. On the other hand, if release of acetylcholine alone, and not its synthesis, were interfered with, one might expect an accumulation and an increase in the amount of acetylcholine in the brain.

Adult male rats (150–250 gm.) were given intraperitoneal injections of methylpentynol in doses varying from 200 to 500 mgm./kgm. At a time shortly after loss of the righting reflex, when the animals were believed to be at the point of greatest central depression, the rats were decapitated, their whole brains (without olfactory lobes and pituitaries) quickly removed and extracted for acetylcholine by the method of Smallman and Fisher[4]. The content of acetylcholine in these extracts was determined by bioassay on the frog's rectus abdominis muscle preparation. Methylpentynol has no direct effect on this preparation in concentrations up to 20 μgm./ml. (approximately seven times the maximal amount expected in the extracts), nor does it sensitize the muscle to acetylcholine. The results are shown in Table 1.

The animals given the lower doses were all lightly depressed, and their acetylcholine-levels were only slightly higher than those of the two control animals. On the other hand, those animals given 500 mgm. of methylpentynol per kgm. were deeply depressed and the levels of acetylcholine in the brain were considerably higher than those of the control animals. It appears that, in rats, methylpentynol causes a rise in the level of acetylcholine in the brain, and that the extent of this rise is related to the degree of depression induced by the administration of the agent. If methylpentynol causes a rise in brain acetylcholine by reducing the output of that substance at certain central synapses, these results would indicate that there is no interference with the synthesis of acetylcholine. It has already been established that methylpentynol does not inhibit cholinesterase (unpublished work).

Table 1. Effect of Methylpentynol on Acetylcholine Content of the Rat's Brain

Intraperitoneal dose (mgm./kgm.)	Killed (min. after onset of anæsthesia)	Acetylcholine in brain (μgm./gm. ± *S.E.*)

Effect of Severing the Olfactory Bulbs on the Intake and Excretion of Water in the Rat

Ecologists and experimental workers maintain that the sense of smell plays an important part both in the search for food and the regulation of alimentary reactions[1–3]. In recent investigations we studied the significance of olfactory signalization for the intake and excretion of water.

Adult male rats in groups of eight or more were used. The skull was trephined above the olfactory bulbs and the bulbs severed with a scalpel: the experiments were begun after a period of 1–2 months. Control animals were sham operated. During the experiment animals were housed individually in metabolism cages, and the intake and excretion of water together with food intake and body-weight were determined.

In the animal house operated animals drink 71 per cent more water a day than normal animals, and the same result was obtained during the experimental period: after their olfactory bulbs had been cut, rats drank 60 per cent more water in a day than the control animals and also excreted 60 per cent more urine. Thus water exchange was the same for both groups.

In order to determine whether increased water intake or increased water loss was the primary mechanism concerned the following experiment was performed. Animals housed in metabolism cages were deprived of food and water for 24 hr. and the amount of urine excreted was measured. It could be shown that operated animals lost 65 per cent more water than control animals during that period.

It seemed possible to explain the above findings by assuming a defect similar to diabetes insipidus. In order to confirm this assumption, adiuretic activity was determined in the blood of our animals using the method of Heller[4]. Its activity was found to be significantly lower in the blood of operated animals than in that of the controls. Exclusion of other sensory receptors (enucleation, severing of the trigeminal nerve) has no effect on water metabolism. Thus severing the olfactory bulbs significantly affects the intake and output of water. It has no effect on food intake and body-weight.

In further experiments it was shown that normal rats make up for the deficit in water due to the 24-hr. period of starvation and thirst by increasing their intake of water on the next day. Operated animals react quite differently. They drink the same amount of water as before the period of thirst. After 24 hr. without access to food and water, control rats excrete urine in the normal fashion. Operated rats under the same conditions urinate less than normally. Only on the next day and afterwards do we find the high excretion of water observed before the period of starvation and thirst. This was also confirmed by a further experiment. Animals were again deprived of food and water for 24 hr. and then given a quantity of water at 38° C. through a stomach tube corresponding to 5 per cent of their body-weight. 3 hr. after the administration of water it was found that more water was retained by the operated rats than by the control ones, the former excreting 40 per cent less water than the latter. It may be concluded that intact rats regulate a water deficit by an increased intake of water, while operated animals react by decreasing urine excretion. Thus these animals, although having less adiuretic activity in their blood, are capable of regulating the volume of their body-fluid.

The changes described do not appear immediately after the operation and on the average become permanent after 20 days. This demonstrates that they are not due to surgical trauma or exclusion of olfactory signalization. It is assumed that they depend on degenerative changes in the olfactory tracts leading to the hypothalamus whence collaterals pass to hypothalamic nuclei. This will have to be verified.

Interrelation of Tryptophan and Nicotinic Acid in Man during the First Month of Life

In the fœtal liver of mammals there is little or no activity of the following enzymatic systems: glucose-6-phosphatase[1], uridine diphosphoglucose dehydrogenase, and glucuronyltransferase[2], phenylalanine transaminase, tyrosine transaminase and phenylalanine hydroxylase[3]. Hence these enzymes reach the normal levels of activity during the first period of extra-uterine life, and for some of them it seems that this process is regulated or accelerated by the adrenocortical hormones.

A similar behaviour has been demonstrated in the rat, in the guinea pig, and in the rabbit as regards the tryptophan peroxidase activity[4]: in the fœtus and newborn of these animals, the conversion of tryptophan into nicotinic acid is diminished or completely eliminated.

We have recently begun an investigation of the tryptophan metabolism in sucklings. In the work to be described in this communication, our particular interest was to examine, in newly born children and sucklings 1 month old, the excretion in the urine, both spontaneous and after administration of L-tryptophan, of the intermediary metabolites of the conversion of this amino-acid to nicotinic acid.

We examined urine samples of normal newly born children and of normal sucklings. The urine was taken every other day, from the first to the thirtieth day of life. For the chromatographic analysis of the urinary metabolites involved in the tryptophan–nicotinic acid system the Dalgliesh technique[5] was used.

Urine samples of 5 breast-fed and of 5 hand-fed children, without administration of L-tryptophan, have been examined systematically during the whole of the first month of life.

In this way, three types of excretory picture, occurring in succession, were observed. The first is characterized by the absence of the metabolites looked for, and lasts from the first to the fourth–eleventh day, varying from child to child; the second phase lasts from the fifth–twelfth day to the seventh–twenty-eighth day and is characterized by the appearance of numerous conjugates of 3-hydroxykynurenine and kynurenine (R_F 0·1–0·15), and of the kynurenine; in 7 out of 10 cases, of 3-hydroxyanthranilic acid; in 2 cases also of anthranilic acid and of 3-hydroxykynurenine; in some of the children the conjugates and the kynurenine appeared before the 3-hydroxyanthranilic acid. The third phase was characterized by the progressive disappearance from the urine of all these metabolites.

However, of the 10 children examined, one excreted with the urine only traces of the conjugates of 3-hydroxykynurenine and of kynurenine (R_F 0·1–0·15), but never the other metabolites looked for. No significant difference in the excretory picture was found between breast-fed and hand-fed children, with the techniques used.

Finally, 2 children were given L-tryptophan *per os* (the first child 150 mgm. and the second 400 mgm.) in single doses on the second, eighth and thirteenth day of life. Their urine was collected for 24 hr. after administration of the drug. In both subjects the dose given on the second day provoked high urinary excretion of L-tryptophan (detected on paper also with the xanthydrole reaction[6]), without the appearance of any other metabolite in the urine. On the eighth and thirteenth day large quantities also appeared of kynurenine, N-α-acetyl-kynurenine, and 3-hydroxyanthranilic acid.

Our results could be, perhaps, explained by the variations during the first month of life of the renal threshold for tryptophan metabolites; or, more probably, by deficiency of the tryptophan–peroxidase activity during the first days of life. There should be, in succession, within the first month, activation of the tryptophan–peroxidase and of other enzymes which catalyse the conversion of the amino-acid into vitamin; if this should happen, during the first days of life the synthesis of nicotinic acid from tryptophan would be completely, or at least partly, inhibited. As is already known, this metabolic route provides in the adult person the synthesis of some tissue pyridine coenzymes[7].

Coenzyme *A* Content of Adipose Tissue

ADIPOSE tissue, long considered an inert storehouse, has recently been shown to have intense metabolic activity. In spite of the importance of coenzyme *A* in fat metabolism, the existence of coenzyme *A* activity had not been demonstrated in adipose tissue. The present communication does so and in addition directs attention to the differences in this respect between normal and obese animals and, among the latter, between animals with 'regulatory' obesity and animals with 'metabolic' obesity[1,2].

The mice used were hereditarily obese hyperglycæmic mice[1,2], approximately five months of age, weighing 51–71 gm., with a blood glucose ranging from 175 to 301 mgm. per cent (av. 242); their thin litter-mates (weight 21–27 gm., blood glucose 82–130 mgm. per cent, av. 93); and thin litter-mates in which hypothalamic obesity had been induced by an intraperitoneal injection of goldthioglucose (crystalline aurothioglucose-*GT*-7-*D*-7-11, Schering Corp., Bloomfield, New Jersey) (1 mgm. per 1 gm body-weight) two months prior to death (weight 44–58 gm., blood glucose 100–245 mgm. per cent, av 168)[1-3]. The first two groups were females, the goldthioglucose groups half males, half females (no sex difference in coenzyme *A*-levels was noted).

All animals were kept in separate cages at 26° C., under regular illumination, maintained on 'Purina chow'. Food intakes were checked during the twenty-four hour period preceding death to ensure that animals were in the fed state.

The coenzyme *A* assay method of Novelli[4] was used. This technique is based on the *in vitro* acetylation of sulphanilamide in an artificially defined medium in which coenzyme *A* is the limiting factor. The enzyme source is a bicarbonate extract of a pigeon liver acetone preparation obtained from Cambridge Biochemicals. The animals were killed by a sharp blow on the head; the abdominal fat was quickly excised, weighed, chilled and homogenized in ten volumes of iced water. The homogenate was boiled for 5 min., cooled (ice bath), centrifuged (10 min. at 1,800 r.p.m.), the lipoid foam discarded and the supernatant stored at –4° C. until assayed. Dry weight was determined by the constant-weight method (90° C. oven); nitrogen content (water-soluble) by alkaline nesslerization[5] of an aliquot of the homogenate removed before the boiling using a 45-min. digestion with a modified Arnold–Gunning digestion mixture (sulphuric acid, 20 ml.; potassium sulphate, 10 gm.; copper sulphate, 0 1 gm.), followed by addition of alkaline Nessler's solution (Fisher Scientific dil. 1 : 2 with 10 per cent sodium hydroxide). Solutions are read at 420 mμ. Results are given in Table 1.

Table 1. COENZYME *A* LEVELS IN ABDOMINAL FAT TISSUE OF MICE

Type of animal (number per group)	Weight when killed (gm.)	Coenzyme *A* levels (Lipmann units)		
		per gm. wet weight	per gm. dry weight	per 100 mgm. nitrogen (water-soluble protein)
Goldthioglucose obese (9)	45 ± 6	50·89 ± 10·50	62·03 ± 21·30	30·26 ± 6·20
Obese-hyperglycæmic (9)	62 ± 8	40·96 ± 8·26	51·07 ± 20·35	38·80 ± 3·20
Non-obese litter-mates (8)	26 ± 3	79·12 ± 11·08	108·56 ± 25·65	20·59 ± 6·23

Figures after ± are standard deviations.

It was found that: (1) the coenzyme *A* is present in considerable amount in adipose tissue; (2) the coenzyme *A* activity per mgm. nitrogen is significantly greater in goldthioglucose obese mice than in non-obese litter-mates; (3) the co-enzyme *A* activity per mgm. nitrogen is significantly greater in the hereditarily hyperglycæmic obese than in non-obese litter-mates made obese by goldthioglucose administration. The last fact is in accord with the known extreme activity of adipose tissue in this syndrome[6].

If values previously obtained for body composition in non-obese mice and mice with the two obese syndromes[7] are accepted, and if it is assumed that the adipose tissue of the animals is homogeneous with respect to the coenzyme *A* concentration, the total coenzyme *A* content (Lipmann units) would be: non-obese 100–150 units, obese-hyperglycæmic approximately 1,200 units and goldthioglucose mice 600–700 units.

An attempt was made to demonstrate the presence of the entire acetylation system (enzyme and co-factors as well as coenzyme) in adipose tissue. The procedures of Lipmann[8] and of Luukkainen[9] were used. No activity could be demonstrated in intact tissue 'cuttings' or in 'unfortified' homogenates. Some activity was seen when a 10-vol. homogenate was incubated for 2 hr. with the 'assay mix' fortified with adenosine triphosphate prepared according to the coenzyme *A* method of Novelli[4].

Control of Colour Change in Amphibians

THE adaptation of colour in anurans to the background is controlled by hormones. Direct innervation of the melanophores is of little or no importance in controlling the degree of dispersion of the melanin-containing granules within the melanophores[1]. It is generally agreed that a melanin-dispersing hormone is produced in the pars intermedia of the hypophysis and that this hormone, intermedin, is responsible for the darkening of the skin. It is, however, controversial whether the paling upon transfer to a white, illuminated background is due to the disappearance of intermedin from the blood, or to the secretion of a whitening hormone.

Hogben *et al.* argue for the participation of a whitening hormone in the colour response to the background[2]. Their theory can be summarized as follows: light-stimulation of the ventral area of retina causes reflex liberation of intermedin; light-stimulation of the dorsal area of the retina causes liberation of whitening hormone. An amphibian (for example, *Xenopus laevis* on which most of their experiments have been made) kept on a black, light-absorbing background and illuminated from above is therefore dark due to liberation of intermedin. When transferred to a white, light-scattering background the animal becomes pale, because now both the ventral and dorsal retina are stimulated, and whitening hormone secreted in addition to the intermedin. The whitening hormone should thus be capable of completely over-riding the melanin-dispersing activity of intermedin. The whitening hormone is assumed to be produced in the pars tuberalis of the hypophysis[2,3] But also the adrenal medulla[4] and the pineal gland[5] have been considered as sites of origin of a whitening hormone.

In order to decide whether a whitening hormone does or does not participate in the normal control of the colour response to a white, illuminated background, we denervated the neuro-intermediate lobe in *Bufo bufo* and *Xenopus laevis* by cutting, in its entire width, the thin wall of the third ventricle which separates the neuro-intermediate lobe from the median eminence and infundibulum. In some operations, part of the neuro-intermediate lobe was extirpated; in others the lobe was transplanted to an eye muscle. So in all the operations the structures supposed by Hogben *et al.* to control the liberation of the whitening hormone were left intact. The operations exclude a nervous regulation of intermedin secretion, whereas a nervous regulation of secretion of the whitening hormone should still be possible—provided the whitening hormone is not secreted by the neuro-intermediate lobe. If a whitening hormone is released into the blood stream when operated animals are transferred from a black to a white illuminated background, and if the secretion is inhibited on retransfer to a black background, such fluctuations in the rate of secretion might be detectable by observation of the state of the melanin within the melanophores.

Table 1. MELANOPHORE INDEX IN *Xenopus laevis* ON ILLUMINATED WHITE OR BLACK BACKGROUND

		Melanophore index. Background White	Melanophore index. Background Black
X.1 *X*.2 *X*.3 *X*.4	Neuro-intermediate lobe denervated	3·6 3·8 4·0 2·2	3·8 3·8 3·6 3·8
X.5 *X*.6 *X*.7 *X*.8	Neuro-intermediate lobe denervated + partly extirpated	2·4 1·7 4·0 4·0	2·0 1·0 4·3 4·2
	Average of five normal *Xenopus*	1·1	4·3

Readings of the melanophore index were made according to Hogben. Melanophore index of 1 stands for maximally concentrated and of 5 for maximally dispersed melanin within the melanophores. The animals were kept for 24 hr. or more on the white or black background before the melanophore index was read. The background was changed repeatedly, mostly every day. In Tables 1 and 2 each melanophore index represents the average of readings from six or more changes of background.

It appears from Tables 1 and 2 that in seven out of eight *Xenopus* and in twenty out of twenty-one *Bufo* the colour (melanophore index) was independent of the background during some weeks after operation, even when melanin dispersion was submaximal, that is, when secretion of intermedin from the denervated neuro-intermediate lobe was submaximal. (Submaximal dispersion of melanin *in vitro* is produced by

† *B*.1–*B*.9 before operation.

high concentrations of intermedin[6]. The submaximal dispersion of melanin frequently observed in operated animals was, however, not due to excess secretion of intermedin from the denervated neuro-intermediate lobe, because injection of intermedin into such animals produced maximal dispersion of melanin.) It can therefore be concluded that if a whitening hormone is secreted in response to a white background it is present in the blood in amounts too small to modify visibly the effect on the melanin dispersion of even small amounts of intermedin. Paling upon transfer to a white background must result from the disappearance of intermedin from the blood. The fact that two animals, *X*.4 and *B*.9, did respond to the background after the operation does not necessarily disprove this conclusion. The persisting colour response can be due to incomplete denervation of the neuro-intermediate lobe.

It is generally agreed that intermedin secretion from the pars intermedia is controlled by inhibitory nerves, because lesion of hypothalamus or transplantation of the pars intermedia has been observed to darken the operated animal permanently[7]. We found, however, that the rate of intermedin secretion from a denervated neuro-intermediate lobe can vary from high to zero, as judged from the state of the melanophores. The toads especially operated during the breeding season were pale after the operation. The normal secretion of intermedin is therefore probably regulated by both inhibitory and secretory nerves.

HÆMATOLOGY

M_1, a Subdivision of the Human Blood-Group Antigen M

A 'NEW' antibody, anti-M_1, has been found as a component in six out of twenty available human anti-M sera: in one of them practically all the antibody was anti-M_1. No anti-M_1 could be detected in anti-M sera from eight rabbits and from one horse, nor in an extract of the seeds of *Iberis amara* (which contains anti-M): nor could it be found in a wide range of other antisera. We are calling the antibody anti-M_1, because in several ways it behaves like anti-A_1 of the ABO system and anti-P_1 of the P system.

The corresponding antigen, M_1, differs qualitatively from ordinary M. It is not merely strong M, because our two best anti-M_1 sera are insensitive to the greater amount of M known to be present in cells representing the genotype *MM* than in those representing the genotype *MN*; and, conversely, because two anti-M sera in our collection which are particularly sensitive to this 'dosage' difference make no distinction between M_1 and ordinary M. The Ss antigens do not appear to be playing a part in the M_1–M_2 difference.

Preliminary tests established that the antigen M_1 is commoner in Negroes than in Whites: they also showed that there is considerable variability in the strength of the antigen and that the classification of the weaker reactions may be left in doubt. Because of this difficulty we decided to confine the present report to classifications based on the results of rather laborious quantitative tests in which strictly comparable cell samples were used. When better anti-M_1 sera are available we hope it will be possible to classify routine cell samples without using quantitative methods.

Samples of blood from 32 New York Negroes and 32 Whites were taken on the same day at the Knickerbocker Foundation and sent by air to London. There they were tested against titrations of six sera containing anti-M and anti-M_1 in different proportions, and against titrations of three anti-N sera, one anti-S and one anti-s. The results given in Table 1 indicate that M_1 is about four times more frequent in Negroes than in Whites.

Table 1. RESULTS OF TESTING SAMPLES OF BLOOD FROM 32 NEGROES AND 32 WHITE PEOPLE WITH ANTI-M_1

		Negroes			Whites		
		M	MN	N	M	MN	N
Anti-M_1	+	3	5	0	2	0	0
	–	4	12	8	8	15	7

A genetic background for these antigenic differences can be provided most simply by postulating three alleles, M_1, M_2 and N, the approximate frequencies of which are:

	M_1	M_2	N
Negroes	0·18	0·35	0·52
Whites	0·03	0·52	0·45

Recombined, these figures give expectations in the five phenotype (six genotype) classes which agree very closely with the numbers observed in both the Negro and the White series. This, to say the least, does not contradict the hypothesis that two kinds of M alleles are responsible for the M_1–M_2 antigenic difference; but we hope for more direct support when appropriate families can be tested.

We wish to thank Dr. Gerald E. Fox and Sister M. Gabriel, O.S.F., of the Blood Bank, St. John's Hospital, Springfield, Illinois, for sending the serum which first attracted our attention to the M_1–M_2 difference. Other acknowledgments will be made in a more detailed account which will be submitted for publication elsewhere.

Separation of the α- and β-Chains of Globins by Means of Starch-gel Electrophoresis

THE investigation of the molecular weight and the electrophoretic behaviour of globins at pH 2–4 has led to a better understanding of the structure of the hæmoglobin molecule. At a pH less than 6 there is a progressive decrease of the molecular weight of human hæmoglobin[1]. At pH 11 the value of the sedimentation coefficient is 2·55, which points to a molecular weight of about 33,000 instead of 67,000, a value normally found[2].

In an indirect way, Singer and Itano[3] demonstrated that the dissociation at a low pH is asymmetrical. Moving-boundary electrophoresis at pH 11[2] leads to the assumption that the molecule is split into two identical halves[2].

Reichmann and Colvin[4] estimated a molecular weight of 16,000 at pH 2 for horse globin. From the electrophoretic behaviour of globin in acid medium, these authors were able to show that more than one component was present.

Haug, Smith and Wilson[5,6] were able to isolate two different components from horse globin, by fractionated precipitation with acid acetone, by moving boundary electrophoresis and by a chromatographic procedure at low pH. Hunt[7], using the same chromatographic method, separated the α- and β-chains and the α- and γ-chains, respectively, of human adult and fœtal globin. Hill and Craig[8] prepared the α- and β-chains by a counter-current distribution procedure.

This communication is a description of the separation of human adult and fœtal globin in chains by means of starch-gel electrophoresis according to Smithies[9], in formate-buffer pH 1·9 ; $\mu = 0{\cdot}02$. A potential of 120 V. was applied during 16 hr. Globins were prepared[10] from the following hæmoglobins: (*a*) normal adult ; (*b*) chromatographically pure A_1[11] ; (*c*) fœtal purified by the alkali-denaturation method of Chernoff[12].

The electrophoretic pattern of adult globin (Fig. 1*d* and *e*) demonstrates two fast-moving bands of almost equal intensity, and a third band with a smaller mobility. The fast-moving bands are the α- and β-chains of the globin ; this was proved in the following way. Globin was separated into two fractions, the α- and β-chains, using the chromatographic method of Wilson and Smith[6]. After concentration the two fractions were separately applied to the gel (Fig. 1*b*, *c*). Fraction I (α-chain) contains the slower of the two fast bands while fraction II contains the faster band.

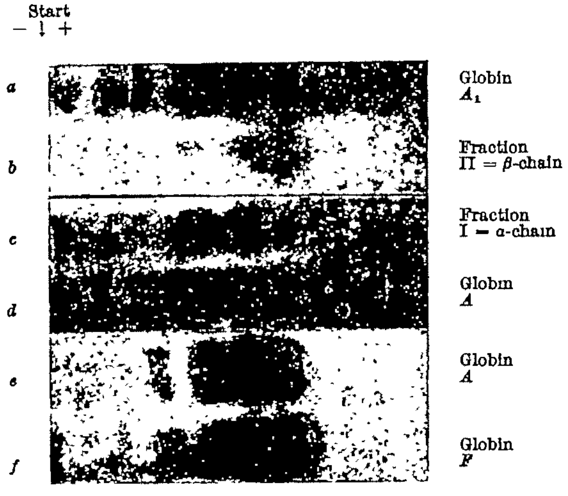

Fig. 1

The electrophoretic pattern of fœtal globin (Fig. 1*f*) compared with the pattern of adult globin (Fig. 1*e*) demonstrates that the α-chains have the same mobility. The mobilities of the β-chains, however, are different. This result is in agreement with the recent findings of Hunt[7].

The nature of the slow band that is present in both separated fractions and in the unfractionated globins is not quite clear. It is possible that they are the result of agglomeration of single chains. Interesting in this respect is the presence of the same band in the electrophoretic pattern of globin of pure hæmoglobin A_1. This excludes the possibility that it is due to the minor components present in the hæmoglobin of an adult human individual. Further research on this third fraction is in progress.

I am much indebted to Prof. J. H. P. Jonxis and Dr. T. H. J. Huisman for their advice and encouragement during this investigation. This work was supported by a grant from the Dutch Organization of Pure Research (Z.W.O.).

Haptoglobin Types in *Macaca irus*

WE have examined the haptoglobin types[1] of ten Cynomolgus monkeys (*Macaca irus*, F. Cuv.). The serum samples have been obtained from the Department of Virus Research, Karolinska Sjukhuset, Stockholm. The monkeys were not born in captivity, but were all captured from wild populations.

The sera were examined by starch-gel electrophoresis, using the discontinuous buffer system described by Poulik[2]. Hæmoglobin from the monkeys was added to the sera prior to electrophoresis, and the resultant gels were stained with benzidine and amido-black.

The resulting protein patterns were, as expected, similar to human serum protein patterns. Two different hæmoglobin-binding serum protein patterns were observed. Double runs revealed that the two patterns were identical with the *Hp* 1–1 and *Hp* 2–1 types found in man. Three of the ten individuals had the *Hp* 2–1 type. It was noted that the *Hp* 2–1 types had a much heavier concentration of haptoglobin in the fastest zone compared with the ordinary human *Hp* 2–1 ; in other words, it resembled the *Hp* 2–1 (mod), cf. Giblett[3].

Arends and Rodriguez[4] have examined the sera from 27 monkeys (23 *Macaca mulatta*, 1 *Macaca irus* and 3 *Cebus nigrivittatus*). All the monkeys were found to have type *Hp* 1–1. The authors suggested that this might be a phylogenetically significant finding, should future investigations confirm that monkeys have only one type of haptoglobin.

The slow-migrating zones of our three heterozygotes were very weak. Such weak types may be overlooked and classified as *Hp* 1–1, especially as the fastest zone is very strong.

The findings by Arends and Rodriguez[4] and our distribution (seven *Hp* 1–1 and three *Hp* 2–1) indicate that the frequency of the *Hp*–1 gene may be high in monkeys. It is then quite reasonable that no *Hp* 2–2 type has yet emerged.

It is known also that African Negroes have a high frequency of the *Hp*–1 gene (refs. 3, 5). Hence this gene might have a selective advantage in tropical areas.

We wish to thank Prof. S. Gard, of Stockholm, for supplying us with the serum samples.

A Re-Evaluation of the Clotting Time of Chicken Blood

The blood coagulation mechanism of the chicken appears to differ greatly from that of mammals, in that its clotting time can exceed 1 hr. Recent literature assumes the chicken to have a blood-clotting time in a range similar to the higher mammals. Dukes[1] quotes Amendt (1922) as finding this to be 4·5 min.; Johnson and Connor[2] found an average of 6 min. 21 sec. with a range of 1–14 min.; while Didisheim *et al.*[3] query their recorded time of 9 min. in glass and 10 min. with siliconized equipment at 37° C. Howell[4], however, in 1909 infers that it is common knowledge that the blood of birds, terrapins and horses clots slowly. In 1940[5] he indicates that prolonged clotting time of hours or days in lower vertebrates (birds, reptiles and fishes) is due to the lack of "thromboplastic substance" within the vessels while prompt clotting is brought about by an active "thromboplastic tissue extract".

In a preliminary determination of clotting times on fifteen chickens using the Lee and White method[6] with plastic or siliconized glass syringes, a range of 1·5–30·0 min. was found at 42° C. It was observed that the negative pressure of the syringe caused a 'fluttering' of the fragile vein against the bevel of the needle and that the greater the degree of 'fluttering', the shorter was the clotting time of the blood. It was assumed from this that the trauma caused by the vein striking the needle released tissue thromboplastin which hastened clotting.

Blood from thirty-seven caged laying hens of three different breeds (Leghorns, Light Sussex and White Rocks) was collected utilizing precautions to minimize the release of tissue thromboplastin. This was done by venipuncture with No. 20 siliconized *B–D* vacutainer needles only. No syringe was used, the blood being allowed to flow directly into 13 mm. × 10 cm. Kimble glass tubes by very slight digital pressure on the superior portion of the brachial vein. Needle movement within the vein was minimized. Clotting times varied from wing to wing, also between the two tubes from each wing; the longest for each bird ranged from 13 to 180 min. with a mean of 69·25 min. (*S.D.* 36·6) (Fig. 1).

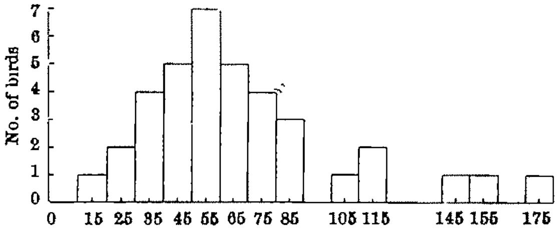

Fig. 1. Distribution of blood clotting times of thirty-seven chickens

Native blood was also timed with a stop watch following the addition of (1) 0·1 ml. of chicken brain thromboplastin prepared by the acetone dehydration method of Quick[7] and (2) 0·1 ml. of chicken thrombin (full strength) made by the technique described by Biggs and Macfarlane[8]. The results are summarized in Table 1.

Table 1. Coagulation Time at 42° C. of Chicken Blood with and without Added Thromboplastin or Thrombin

No. of birds	Material added	Clotting time (sec.)	Control Lee–White clotting time (min.)
21	Chicken thromboplastin	18·4 (11–17·8)	70
15	Chicken thrombin	30·6 (19–50)	64·5

These observations tend to confirm those of Howell[4,5] and indicate: (1) that the blood of the birds tested had generated very little plasma thromboplastin; (2) that the chicken has an efficient blood-clotting mechanism, but that it relies on an active tissue thromboplastin rather than plasma thromboplastin as do mammals; (3) that the shorter clotting times noted here and by other authors may have been due to action by vein wall tissue thromboplastin.

The apparently delayed action of the chicken thrombin in Table 1 is under investigation. A comparison of clotting times at 37° C. and 42° C. revealed only a slightly longer time at 37° C.

HISTOLOGY

Neurokeratin Network of the Peripheral Nerve Fibre Myelin Sheath as a Centre of Metabolic Activity

THE neurokeratin network has long been regarded by histologists as a fixation artefact ; it is figured as such in papers and text-books. Sometimes it is shown as irregular bands radiating through the myelin sheath to the neurilemma, sometimes as a network particularly at the surface of the fibre or around the axon.

However, if fresh unfixed nerve fibres are studied under the interference microscope, an indication that similar structures are present can be seen, which suggests that a network-like structure may be present in the living nerve. Investigations of cryostat sections of fresh unfixed nerves in both transverse and longitudinal section indicated that this network is actually in the form of hexagonal prisms which have one end on the axon and radiate out through the myelin sheath to the neurilemma. The longitudinal faces of these prisms take the form of bands seen radiating through the myelin in transverse and medial longitudinal sections of nerve. The application of Baker's acid hæmatin technique showed that these faces give a positive phospholipid reaction, and osmium-fixed nerve, if extracted with turpentine, shows that the osmium tends to be retained on the faces of the prisms but is extracted from their interiors. Since electron microscopists simply stain overall with osmium tetroxide, perhaps this is why this network has not been described in electron microscope studies of the nerve fibre. On the other hand, the performic acid–Schiff reaction which is claimed to demonstrate unsaturated fats gives a reaction in the spaces which constitute the interior of the prisms. Mitochondrial preparations (Regaud and Schridde methods) of the nerve fibre show that a few bodies giving a positive stain for mitochondria are present in the axon, a number are found around the periphery of the axon and a number are found among the lipid (probably lipoprotein, also giving a positive reaction with these techniques) which forms the faces of the hexagonal prisms—no such bodies are found in the interior of these prisms. Adenosine triphosphatase preparations of fresh unfixed nerve demonstrate that this enzyme is localized in the myelin sheath in the same place as the mitochondrial reaction (that is, in the faces of the hexagonal prisms) and that every phosphate ester (about 20 were tried, including creatine phosphate) used as a substrate was dephosphorylated at the same sites as adenosine triphosphate. Acid phosphatase, on the other hand, was localized exclusively in the axon with the incubation times used. No adenosine triphosphatase or other enzyme activity was observed in the nodes of Ranvier. Studies on oxidative enzymes demonstrated that cytochrome oxidase and succinic dehydrogenase were also located in the same areas as the adenosine triphosphatase. Furthermore, we have also demonstrated that specific cholinesterase is located in and around the axon, and non-specific cholinesterase is located in the faces of the hexagonal prisms.

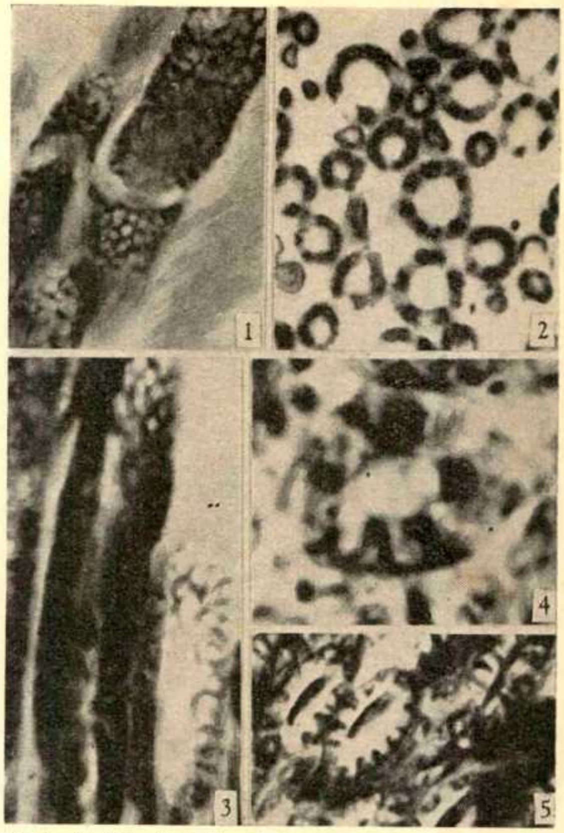

Fig. 1. 1, Adenosine triphosphatase preparation of frog myelinated nerve showing surface view of reaction localized in hexagonal network. On the right of the fibre the plane of section passes through the myelin sheath and the faces of the hexagonal prisms are shown as adenosine triphosphatase-positive bands radiating from the axon to the neurilemma. The node of Ranvier can be seen to contain no adenosine triphosphatase activity. (Preparation and photograph by David G. Shand) (× 1,050). 2, Mitochondrial preparation (Regaud's method) of myelinated nerve of rat. Transverse section. The reaction can be seen to be localized in bands which represent the faces of the hexagonal prisms (× 1,050). 3, Phospholipid preparation (Baker's method) of longitudinal section of myelinated nerve of rat. At the top of the figure the hexagonal appearance of this reaction (surface view) can be seen and further down, where the myelin sheath has been cut, the positive faces of the hexagonal prisms in the myelin sheath are visible (× 1,050). 4, Cytochrome oxidase preparation of a cryostat section of a transverse section of a single unfixed untreated nerve fibre of rat showing the reaction in the form of bands (the faces of the hexagons) radiating out from the axon to the neurilemma (× 2,100). 5, McManus sudan black *B* stain for compound lipids. Transverse sections of nerve fibres of rat. The reaction can be seen to extend in bands radiating out from axon to neurilemma (× 1,050)

The 'neurokeratin' network thus not only appears to be present in unfixed nerve but also to be a locus of major metabolic activity. The space within the neurokeratin network, although it contains lipid and ether- and alcohol-soluble material, gives no reaction with the mitochondrial techniques and contains no dephosphorylating or oxidative enzyme activity. Fig. 2 is an artist's impression of the arrangement of the metabolically active hexagonal prisms in the myelin sheath. It can be seen from this how either transverse or longitudinal sections of the nerve fibre will show the faces of the prisms as bands radiating out from the axon to the neurilemma and how, according to the point of section, some of the bands will appear thick and others thin. The faces of these prisms contain phospholipid, mitochondrial-like lipoprotein, adenosine triphosphatase, creatine phosphatase and a spectrum of other phosphatases, cytochrome oxidase, succinic dehydrogenase, and non-specific cholinesterase.

The possibility that these reactions are artefacts due to freezing, handling or other manipulation has been carefully considered. We feel that the results of our interference microscope studies indicate,

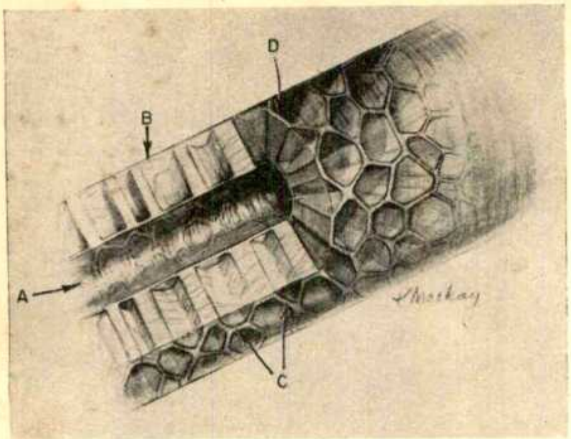

Fig. 2. *A*, Canal normally occupied by the axon ; *B*, neurilemmal sheath ; *C*, end-on view of faces of hexagonal prisms seen from surface of the nerve ; *D*, face of hexagonal prism as seen in transverse section of nerve

though not with absolute clarity, that some structure similar to what we have described may be present in the fresh nerve. Furthermore, our adenosine triphosphatase, cytochrome oxidase and succinic dehydrogenase reactions were carried out on fresh nerve which was simply removed from the animal and dropped straight into the substrate solution. However, all these processes have involved some handling and to compensate for this we have exposed the sciatic nerve in a living, anæsthetized rat without touching or stretching it and dropped buffered osmium tetroxide directly on to it as if we were preparing the material for electron microscopy. After the nerve had been well fixed *in situ*, it was removed, given further fixation in osmium tetroxide, sectioned and the sections were then extracted with turpentine and diacetin—we were able to bring up the neuro-keratin network in the form described in this communication. We feel, therefore, that the evidence for the *in vivo* existence of such a network is strong.

It is perhaps inappropriate to speculate on the significance of this structure at this time ; but perhaps we should mention that if the efflux of sodium and influx of potassium through the myelin sheath itself is important to nerve function and maintenance of membrane potentials, the faces of these hexagons are admirably adapted for this purpose. Conway[1,2] has suggested a redox system for the active transport of sodium ions by adsorption of these ions on to a catalyst molecule. The present work suggests that the catalyst molecules may be phospholipid, and it is of interest that Conway[3] has himself suggested that this may be so. Creatine phosphatase, adenosine triphosphatase and oxidative enzymes as required by Hodgkin[4] for his ion-pump mechanism are also present in these faces and their possible relationship to the physiology of the nerve fibre should therefore be carefully considered.

In the interpretation of these findings we have not taken into account the lamellæ which electron microscopists have described in the myelin sheath, although it is possible from our osmium tetroxide results that there is simply a stronger binding between the lipid and the protein components of the lamellae in the regions which we have described as the faces of the hexagons. Nerve fibres from the following animals were used in this study : frog, mouse, rat, cat, dog and human.

The work will be published in detail elsewhere. It was carried out under grant *B*-1914 from the National Institute of Neurological Diseases and Blindness, U.S. Public Health Service.

Note added April 20. While this communication was in the press Wolfgram and Rose[5] have demonstrated the presence of alkaline phosphatase, 5-nucleotidase (confirming the previous observations of Beckett and Bourne[6]) and adenosine triphosphatase in the neuro-keratin network and Koenig[7] has demonstrated the lipoprotein nature of the network.

PATHOLOGY

Effect of Antibody and Complement on Volume Control in an Ascites Tumour Cell

WHEN Krebs mouse ascites tumour cells are exposed to the action of rabbit antibodies and complement, the permeability properties of the cells are altered in such a way as to permit rapid equilibration of small molecules and ions between the interior of the cells and the medium[1]. This deprives the cells of the ability to regulate their internal cation concentration, which is necessary for normal control of cell volume (ref. 2 and Tosteson, D. C., and Hoffman, J. F., personal communication). As a result, the cell volume then responds passively to whatever colloid osmotic pressure difference exists between the cell interior and the medium. In ordinary media, the colloid osmotic pressure of which is lower than that of the cells, the cells take in water[3,4]. As they swell, they lose protein and ribonucleic acid to the medium[1], probably until the colloid osmotic pressure inside the cells is reduced to that of the medium, when cell volume is stabilized at a new value.

Fig. 1 shows the result of an experiment in which rabbit anti-tumour γ-globulin and complement (fresh rabbit serum) were permitted to act on a washed suspension of ascites tumour cells in a bicarbonate-buffered balanced physiological salt solution containing varying concentrations of crystalline bovine serum albumin (Armour). After 15 min. incubation, a measured aliquot of suspension was placed in a graduated capillary sedimentation tube[5] and centrifuged at $550g$ for 30 min. at 0°. In the absence of added albumin, the antibody-complement treated cells swelled freely, as indicated by an increase of nearly threefold in packed cell volume. At increasing concentrations of albumin the swelling of the cells was progressively reduced, and at concentrations in excess of 110 mgm./ml. the cells were actually smaller than the controls. The volume of the control cells was practically insensitive to changes in albumin concentration, whether antibody was present or not. In most experiments, however, there was a slight increase in packed volume at high albumin concentrations, but this was probably due to poorer

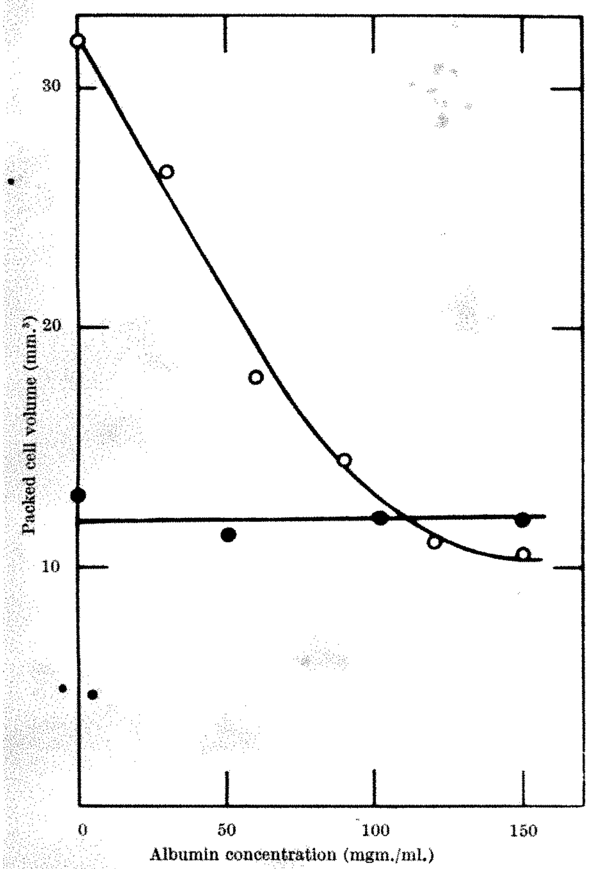

Fig. 1. Effect of albumin concentration on the packed volume of tumour cells treated with antibody plus complement.
To flasks containing 0·90 ml. of bovine albumin solutions of varying concentration were added 0·15 ml. immune rabbit γ-globulin (68 mgm./ml.), and 0·15 ml. washed cell suspension ($5·4 \times 10^7$ cells/ml.). To the experimental series 0·30 ml. rabbit complement was then added and to controls 0·30 ml. of heat-inactivated complement. After 15 min. incubation at 37°, while gently shaking in a water-bath, 1·0 ml. aliquots from each flask were placed in graduated capillary centrifuge tubes (ref. 5) and centrifuged.
○, Cells incubated in presence of antibody plus complement;
●. cells incubated in presence of antibody plus inactivated complement

packing of the cells in the denser and more viscous medium.

The decrease in the packed volume of the antibody-complement treated cells with increasing albumin concentration is not due to inhibition of the action of antibody and complement on the cells, since at high albumin concentrations the volume of these cells fell below that of the controls. Moreover, measurement by flame photometry of the potassium ions remaining in the packed cells showed a constant loss from the treated cells of most of their potassium ions over the whole protein concentration range, demonstrating that the antibody and complement had acted on the cells[1].

It appears from Fig. 1 that the colloid osmotic pressure of the cells is equal to that given by a solution containing 110 mgm./ml. serum albumin plus the proteins of the complement and immune γ-globulin. Assuming that globulins contribute half as much to the osmotic pressure as does albumin, the total colloid osmotic pressure would be equivalent to that of an albumin solution of about 130 mgm./ml.

Packed cell volume in these experiments was measured after 15-min. incubation. If, however, cells in albumin concentrations even higher than 110 mgm./ml. were observed in the phase microscope immediately after addition of antibody and complement, a transitory swelling of the cells was observed. After a very few minutes, however, this swelling was arrested and the cells shrank to a size which thereafter remained constant. This transitory swelling may be due to a temporarily more rapid influx of cations than efflux, a hypothesis suggested by Dr. John Cook and supported by the observation that the transitory swelling was largely abolished if sodium ion in the medium was replaced by an equimolar concentration of the larger, more slowly penetrating ion, choline.

It appears, therefore, that for cells which are able to regulate their cation concentrations, cell volume is not detectably sensitive to changes in the albumin concentration in the medium, for the osmotic pressure contributed by even the highest albumin concentration examined, $2·3 \times 10^{-3} M$, is negligible compared with that of the regulated cations. These cells are, of course, shrunk by relatively high molar concentrations of sucrose ($0·5 M$), to which the cell membrane is also impermeable. On the other hand, cells acted on by antibody and complement are not shrunk by sucrose, for the cell membrane becomes freely permeable to small molecules and ions[1]. For the same reason, these cells act as osmometers responding passively to the osmotic pressure of those macromolecules which are sufficiently large so that they cannot pass through the altered cell membrane.

Changes in the Deoxyribonucleic Acid Content of Mouse Sarcoma 37 Cells following Serial Irradiation

CHANGES in the deoxyribonucleic acid content of human tumour cells following irradiation have been reported by Richards and Atkin[1] and Atkin, Richards and Ross[2]. There exists strong evidence in support of a positive relationship between modal deoxyribonucleic acid content and the degree of ploidy; this has been discussed by Atkin and Richards[3], and Richards and Atkin[4]. This communication reports changes in content of deoxyribonucleic acid in the mouse sarcoma 37 following serial irradiation.

The tumours selected for study were taken from untreated control transplants and from the twentieth untreated sub-line passage of the twelfth stage of the serially irradiated line (*B*12). Although the irradiated line at this stage varied from the control with respect to histology and cytology, no subsequent variations occurred during sub-line passages. Details of the techniques employed in establishing the irradiated line have been given elsewhere[5]. Smears of isolated cells from the cortex of actively growing tumours were prepared as described by Atkin and Richards[3]. The amount of deoxyribonucleic acid in individual cell nuclei was estimated by microspectrophotometry of Feulgen stained material. Two tumours from each group were used; 72 cells were measured in each of one pair (Fig. 1, *A* and *C*) and 45

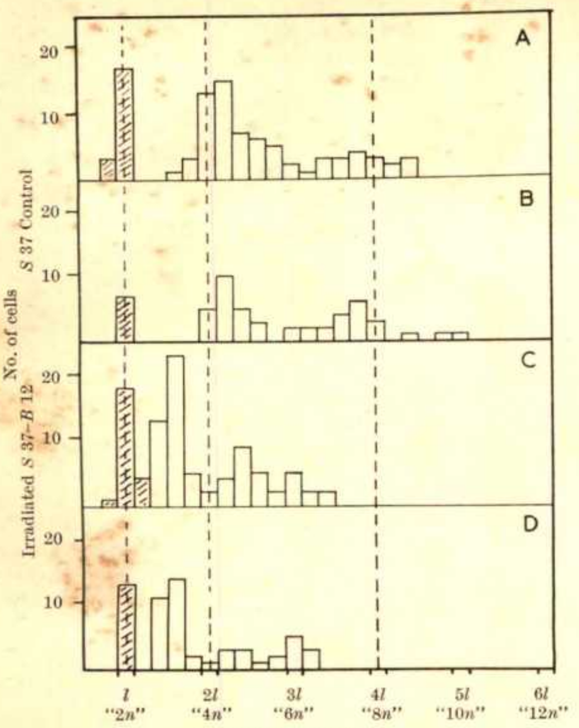

Fig. 1. Measurements of deoxyribonucleic acid in cells of sarcoma 37 and its serially irradiated line *B*12. Shaded regions, leucocytes; unshaded regions, tumour cells

cells in the second (*B* and *D*). In addition, 14–20 polymorphonuclear leucocytes and lymphocytes were measured from each tumour preparation to provide a modal value corresponding to the diploid level (the l value).

The results of these measurements are shown in Fig. 1 in the form of histograms having 10 classes between the $2l$ and $4l$ values. Control tumours exhibited a primary mode in the tetraploid region with an extensive spread to the hyperoctoploid region. Irradiated line tumours exhibited a primary mode corresponding to a triploid condition with a less extensive spread towards higher values than was found in control tumours.

It is apparent that the modal deoxyribonucleic acid value of the irradiated mouse tumour line differed from that of the unirradiated control. Radiosensitivity comparisons between the two lines, however, indicated that no changes had occurred in the tumour lethal dose; at lower dose-levels, an increased radiosensitivity was apparent in the irradiated line[5]. It seems, therefore, that the changes observed cannot be correlated with the acquisition by the irradiated line of radioresistant characteristics. In this connexion it is of interest that serial observations on the content of deoxyribonucleic acid of two human cervical carcinomata, which responded poorly to radiotherapy, strongly suggested the emergence following treatment of a stable radioresistant cell strain having in both cases a triploid deoxyribonucleic acid content from what was originally a mixed population[1]. The accumulated data on human uterine tumours[1,2] show that there is no clear-cut correlation between ploidy-level and response to radiotherapy, although near-diploid tumours appear to give rise to fewer local recurrences than do those with higher modal values of deoxyribonucleic acid.

Our thanks are due to Mr. D. Doxey for assistance with the preparation of cell smears. The deoxyribonucleic acid measurements were made in collaboration with Dr. B. M. Richards, at the Wheatstone Physics Laboratory, King's College, London.

The expenses of this research were defrayed from a block grant by the British Empire Cancer Campaign.

BIOLOGY

Nuclear Morphology of Human Spermatozoa

THIS communication concerns observations on dried, unstained smears of human spermatozoa in phase contrast. These were made in an attempt to gain more insight into the basis for the known differential in conception and birth sex ratios.

Spermatozoa from forty men were studied. Thin smears were allowed to dry. Observations became clearer with increase in extent of drying. The dry phase objectives and condensers were used. Oil immersion and wet preparations in seminal fluid did not permit observation of nuclear detail, that is, the chromosomes accentuated their own visualization in phase contrast in the dried state. A Zeiss phase-contrast microscope with built-in accessory scope was used. A Leica camera with 'Ibso' attachment and 'Microfile' film was employed.

Under these conditions, lying horizontally, the spermatozoan heads fell into two distinct populations (Figs. 1–3). There were no intermediate types. Reflexion of light was different for the two kinds

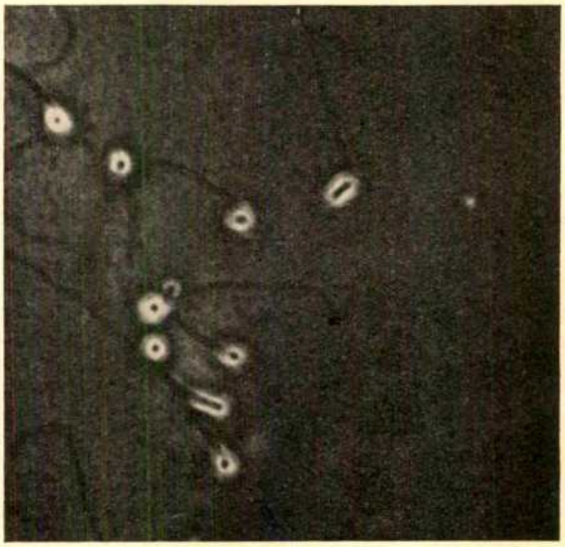

Fig. 1. Dried, unstained smear of human spermatozoa in phase contrast. (× 640)

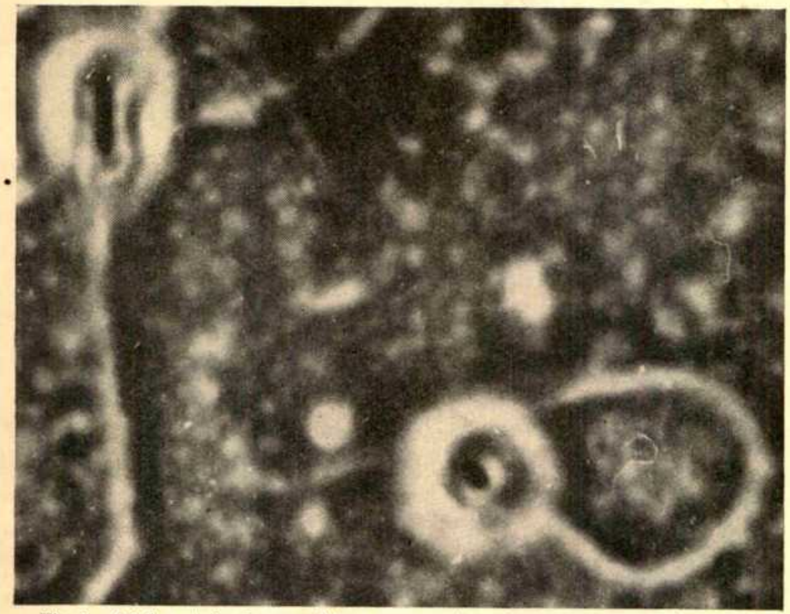

Fig. 2. Dried, unstained smear of human spermatozoa in phase contrast. (× *c.* 750)

(Figs. 1 and 2). The smaller-headed spermatozoa contained a centrally located, rounded mass, whereas the larger-headed ones had an elongated mass, centrally located. These masses lay anterior to, and in line with, the axial filament of the mid-piece. There was a definite, constant pattern of nuclear content in each type, conforming in outline to the respective, most central chromosome (Fig. 3). In the smaller-headed spermatozoa the nuclear material was arranged with circular concentricity; in the larger-headed ones, the nuclear material had an elliptical or ovoid configuration. The pattern of arrangement remained characteristic and recognizable for each of the two types of spermatozoan heads, in front and side views and while varying the focus. The nuclear content of the larger-headed spermatozoa was less compact; consequently more detail was seen at different focal levels here. In one head of this type three observers counted independently 18 discrete chromosomes at different focal levels. With proper combination of condenser and dry objective the difference in diffraction of light by the chromosomes markedly enhanced their visibility, as though they were stained differentially. This made it possible to photograph them in colour.

The most centrally situated chromosome in each type of nucleus possessed the exact size and shape relationships of the X and Y chromosomes previously observed in the primary and secondary spermatocytes at metaphase in meiosis (Fig. 3).

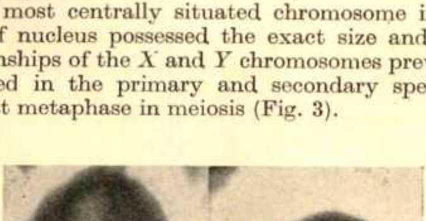

Fig. 3. Dried, unstained smear of human spermatozoa in phase contrast. (× 1,000)

Even though the characteristics were remarkably constant for the two types of spermatozoan heads within a given specimen, the overall head-size varied from individual to another. In some donors the respective head-sizes were twice as great as in others. Even though actual percentages were not ascertained for each type in each specimen, it was readily noted that the ratio was not the same in all specimens, and that there was a preponderance of the smaller-headed spermatozoa in each specimen. Further observations are being made on the ratio of the two kinds in a large number of specimens and in varied circumstances.

Any differential in migratory rate of the two kinds of spermatozoa can now be investigated with ease by means of the capillary tube method[1]. This is now being studied. With the two distinct types now recognizable, the efficacy can be checked of attempts to separate the X- and Y-chromosome-containing spermatozoa.

In summary, viewed in phase contrast, dried, unstained spermatozoa fall into two distinct populations regarding head and nuclear size, shape, diffraction of light and chromosomal pattern. With knowledge of the behaviour of the sex chromosomes at metaphase of the meiotic division of the primary and secondary spermatocytes, the relative sizes and shapes of the chromosomes in the centre of the spermatozoan nuclei indicate that the smaller heads contain the Y- and the larger the X-chromosome.

Dependence of the Sex Ratio at Birth on the Age of the Father

RECENTLY I have attempted to develop a general theory of ageing applicable to mammals[1]. This theory assumes that, during the life-time of the animal, whole chromosomes, which are contained in the somatic cells, suffer a total loss of function in a single random event. It further assumes that the probability of such an event remains constant throughout life-time and that it is the same for all individuals of a given species.

From the American life-tables I have derived, on the basis of the theory, the frequency with which such random events occur in man and found that on the average one chromosome, of the haploid chromosomal set of the somatic cell, suffers such a 'hit' in about twelve years. If we assume that this holds also for the spermatogonia in man, we should then expect that the ratio of boys and girls, at birth, decreases appreciably with the age of the father. This conclusion is based on the following notions:

We may assume that any cell of the male becomes non-functional if the *X* chromosome for which the cell is hemizygous suffers an ageing hit, that is, the absence of the *X* chromosomes is lethal for the somatic cell in the male. The absence of the *Y* chromosome is not lethal for the somatic cell and, as a matter of fact, it need not be lethal even for the zygotes; there exist individuals whose cells contain one *X* chromosome and no *Y* chromosome and these exhibit Turner's syndrome.

Accordingly, if the *X* chromosome in a spermatogonium suffers an ageing hit, then the cell is eliminated; if the *Y* chromosome in a spermatogonium suffers an ageing hit, then the cell remains fully functional and will give rise to spermatozoa, but only to spermatozoa which contain an *X* chromosome.

The length of the *Y* chromosomes amounts to about 2 per cent of the total length of the haploid set of the autosomes[2] and on this basis we may perhaps assume that an average of 2 per cent of the *Y* chromosomes of the spermatogonia suffer an ageing hit in a 12-year period.

We may assume that some spermatogonia are lost due to causes other than ageing and are replaced by other spermatogonia undergoing divisions. Then if spermatogonia which lack a functioning *Y* chromosome divide at the same rate as spermatogonia which carry a functioning *Y* chromosome, the ratio, at birth, of boys and girls would decrease by 2 per cent for a 12-years increase in the age of the father, and by 4 per cent for a 24-years increase. However, if the spermatogonia which lack a functioning *Y* chromosome undergo divisions at a somewhat lower rate, then the ratio of boys and girls would, initially, decrease with the father's age at the rate quoted above, but the ratio would approach a fixed value with increasing age of the father.

One may compute on the basis of birth data[3] for the United States, 1955, the dependence of the ratio of boys and girls on the age of the father. For the age-group of the father indicated and for the sample sizes—for boys alone or girls alone—given in brackets, the ratios are as given in Table 1.

Table 1

15–19 yr. (~ 46,000): 106·7; 20–24 yr. (~ 410,000): 105·7;
25–29 yr. (~ 590,000): 105·0; 30–34 yr. (~ 440,000): 105·0;
35–39 yr. (~ 250,000): 105·0; 40–44 yr. (~ 120,000): 104·1;
45–49 yr. (~ 45,000): 103·6

These data do not take into account the age of the mother, and there is, of course, a strong correlation between the age of the father and the age of the mother. What one would want to know is the dependence of the sex ratio at birth on the age of the father, for a fixed age of the mother. However, if one tabulates the available data on this basis the sample sizes become too small.

From the data given in Table 1 it would appear that the ratio of boys and girls does fall with increasing age of the father. It will not be possible, however, to draw conclusions which are relevant from the point of view of the theory until the data based on larger samples become available.

Neuro-Muscular Transmission in the Earthworm

Neuro-muscular transmission was investigated in the earthworm, *Lumbricus terrestris*, by stimulating a segmental nerve with maximal shocks and recording the electrical responses from the surface of the longitudinal muscle.

A single action potential was recorded to each shock, and from latent period measurements it was calculated that conduction velocity in the motor neurones was of the order of 0·4 m. per sec. This slow velocity suggests that, unlike the situation in *Myxicola*[1] and certain other polychaetes[2], there are no rapidly conducting giant axons in the segmental nerves of *Lumbricus*.

At frequencies greater than 1 per sec. the first muscle potential was found to be consistently smaller than subsequent ones (Fig. 1). In a very few preparations there was a gradual increase in size over the first three responses. In greatly fatigued preparations the response to the first shock was much reduced, though never completely absent, and the difference between the first and second responses particularly marked.

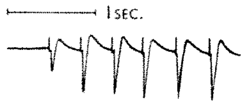

Fig. 1. *Lumbricus terrestris*: longitudinal muscle potentials in response to repetitive stimulation of segmental nerve at three shocks per sec. Tracing of original oscillograph record. Each potential preceded by upward-projecting stimulus artefact

If the frequency of stimulation is gradually increased the size of the muscle potentials also increases. For example, in one preparation (Fig. 2) the segmental nerve was stimulated initially at just less than one shock every 2 sec. and the approximate height of the muscle potentials, measured from the oscillograph trace, was 7·5 mm. The frequency was then increased to 3 per sec. and the muscle potentials rose to 13 mm., being maintained at about this height until after several seconds the frequency was decreased again.

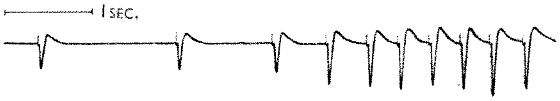

Fig. 2. *Lumbricus terrestris*: longitudinal muscle potentials in response to repetitive stimulation of segmental nerve at gradually increasing frequency. Tracing of original oscillograph record. Each potential preceded by upward-projecting stimulus artefact

With prolonged repetitive stimulation the potentials, after being maintained for a short while, undergo a gradual decline in magnitude, the number of shocks required to induce fatigue depending on the frequency of stimulation and the freshness of the preparation.

Determination of Physiological Age for Female *Glossina morsitans*

Recently, considerable attention has been paid to a method of determining the physiological age of female insects of economic importance by the appearance of the ovarioles after ovulation. This method, which was originally worked out by Soviet entomologists[1,2] for *Anopheles*, and has since been extended to other blood-sucking Diptera, depends upon the recognition of the number of follicular relics ('corpora lutea') appearing as dilatations of the follicular tubes. Each dilatation represents the relic of a single egg follicle and is evidence of a gonotrophic cycle. If the duration of the cycle is known it is possible to calculate the calendar age of the female, a factor of great practical application in determining the epidemiological importance of populations of insect vectors or the degree of success of control programmes. In the laboratory, Bertram and Samarawickrema[3] recognized *Mansonioides uniformis* which had completed five gonotrophic cycles by the presence of five dilatations in the follicular tubes. A study of the ovarioles of *Glossina morsitans* after ovulation has been made, and it is suggested that a similar method of determining the physiological age of female tsetse flies should be possible.

Each ovary of *G. morsitans* consists of two polytrophic ovarioles, each at a different stage of development[4]. Only one egg matures at a time, and a sequence of ovulation occurs so that the first and third eggs are ovulated from the right ovary and the second and fourth eggs from the left ovary. Subsequent eggs are produced from each ovariole in a continuation of the same sequence.
